## CONTENTS OF VOL. XXVII, NO. I.

---

Editorial notes:	Page.
The need for research in home economics.....	1
Recent work in agricultural science.....	7
Notes.....	98

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

A study of humus in Hawaiian soils, Kelley and McGeorge.....	7
The detection of nitrates with diphenylamin, Caron.....	8
The determination of nitrogen in commercial ammoniates, Rudnick et al.....	8
An apparatus for preparing ammonium citrate solution, Vecchi.....	8
Methods for determining the hardness of natural waters, Silber.....	9
Determination of proteins and the digestion of protein by pepsin, Westhauser..	9
The measurement of the oxidase content of plant juices, Bunzel.....	9
On the determination of dry matter in roots, Goldschmidt.....	9
A study of the carbohydrates in the prickly pear and its fruits, Hare.....	9
The analysis and composition of grapes, Brunet.....	10
The composition of the apple as affected by irrigation, Bradley.....	10
Investigations in regard to the composition of pear and apple seeds, Huber....	11
The hydrocyanic acid content of some seed and stone fruits, Huber.....	11
Analysis of mustard flour, Domergue.....	12
A recently discovered bacterial decomposition of sucrose, Owen.....	12
A new method for estimating sugar, von Fillinger.....	12
Extraction of grains and cattle foods for determination of sugars, Bryan et al...	12
Detection of salicylic acid, Sherman and Gross.....	12
Differences in cleavage of casein, paracasein, and calcium paracaseinate, Hösl..	12
Boiling test, alcohol test, and acidity degree of milk, Rammstedt.....	13

	Page.
The guaiac test for distinguishing raw and boiled milk, Schern and Schellhase..	13
The blue coloration obtained with tincture of guaiac, Tewes.....	13
The Schardinger reaction for milk, Rullmann.....	13
The catalase reaction for milks from cows affected with mastitis, Huynen.....	14
Volatile acidity of gum tragacanth compared with that of Indian gum, Emery..	14
Determination of nicotin, Bertrand and Javillier.....	14
An electrically controlled constant-temperature water bath, Gore.....	14
Mixing, stirring, and kneading, and the machines used, Fischer.....	14
International catalogue of scientific literature. D—Chemistry.....	14
Yearly report of progress made in agricultural chemistry, edited by Dietrich...	14
Report of the official agricultural laboratories of Belgium, 1910.....	14
Modern chemical technology, edited by Dammer.....	14
Yearly reports in regard to the fermentation organisms, Koch.....	15
Manufacture of starch, Rehwald.....	15

## METEOROLOGY—WATER.

The climate of Switzerland, Maurer, Billwiller, jr., and Hess.....	15
The influence of rain and temperature on cereal crops, Kharizomenov.....	15
Precipitation in Havana in each month of the years 1859 and 1908, Müller.....	15
Protection of Beaujolais against hail by electric barrages, Perraud.....	15
Water powers of North Carolina.....	15
The origin and wholesomeness of the saline waters in the London Basin, Thresh.	16
Purification tests of the water supply of Marseille, Arnaud et al.....	16
Utilization of sludge in England, Batley.....	16
Sewage sludge disposal, Batley.....	17
The private sewage disposal plant, Manning.....	17

## SOILS—FERTILIZERS.

Soils of the eastern United States and their use, XXIX—XXXV, Bonsteel.....	17
Soils of the Shenandoah River terrace: A revision of certain soils, Bennett.....	18
Soils of the San Luis Valley, Colo., Lapham.....	18
Agricultural possibilities of the Canal Zone. Part I, Soil survey, Bennett.....	19
Records of drainage in India, Leather.....	19
Lysimeter investigations, 1911, Krüger.....	19
The flow of subsoil water, Hurst.....	20
The conservation of the soil, Grégoire.....	20
The absorption phenomena of cultivated soils, Aberson.....	20
The biological absorption of soils, Stoklasa.....	20
Biochemical relations of the phosphate ion in the soil, Stoklasa.....	21
Loss of ammonia from soils and experiments on nitrogen balance, Ehrenberg.	21
The loss of ammonia from manured soils, Ehrenberg.....	21
The loss of ammonia from soils, Liechti and Ritter.....	21
Green manuring in Mysore, Coleman, Iyengar, and Sampatiengar.....	21
The smells of manure works of Paris, Boudouard.....	21
Fertilizer resources of the United States, Cameron, Moore, et al.....	22
Potash salts: Summary for 1911, Phalen.....	23
An investigation of the Otero Basin, New Mexico, for potash salts, Free.....	23
Potash from the Pacific kelps.....	23
Leucite as a potash fertilizer, Bonomi.....	23
On the economic use of potassic fertilizers, Bonomi.....	24
Comparative tests of calcium and sodium nitrates as fertilizers, Bonomi.....	24
Chilean production of nitrate, Winslow.....	24
Lime for Alabama soils, Duggar and Funchess.....	24
Liming the soil, Abbott.....	24
The uses of peat for fuel and other purposes, Davis.....	24

## AGRICULTURAL BOTANY.

British fungi and lichens, Massee.....	25
Enzym studies of lower fungi, Dox.....	25
Oxidizing enzymes in certain fungi pathogenic for plants, Reed and Stahl.....	25
The root nodules of <i>Myrica gale</i> , Bottomley.....	25
The morphology of the root tubercles of <i>Alnus</i> and <i>Eleagnus</i> , Spratt.....	25

	Page.
Nitrogen nutrition of <i>Aspergillus niger</i> , Brenner.....	26
The rôle of nitrogen in plant metabolism, Perrie.....	26
Can humus be directly assimilated by the higher plants? Molliard.....	26
The influence of phytin on seedlings, Rose.....	26
The action of sulphur on plants, Boullanger.....	27
The effect of ether and carbon bisulphid on plants, Koch.....	27
Effect of guanidin on plants under different conditions, Schreiner and Skinner.....	27
The influence of chemicals on the germinating capacity of dodders, D' Ippolito.....	28
Sterilization of seed in relation to micro-organisms contained by them, Rossi.....	28
Influence of continued electric currents on the growth of plants, Kövessi.....	28
The liberation of heat in respiration, Peirce.....	28
Incipient drying in plants, Livingston.....	29
The water balance of desert plants, MacDougal.....	29
The relation of soil acidity to plant societies, Sampson.....	29
The weeds of arable land in relation to the soils, H, Brechley.....	29
Toxic excreta of plants, Fletcher.....	30
The injurious influence of tarred roads on neighboring vegetation, Mangin.....	30
<i>Lotus corniculatus</i> , a cyanophoric plant, Armstrong and Horton.....	30
Investigations on heredity, Johannsen.....	30
On the cause of dimorphism in <i>Oenothera nanella</i> , Zeijlstra.....	30
Contribution to the study of buds, Perriraz.....	30
Graft hybrids, Gregory.....	31
International catalogue of scientific literature. M—Botany.....	31

## FIELD CROPS.

Classification of field crop varieties, Merkel.....	31
[Wisconsin farm crops experiments], Russell.....	31
Results of cooperative experiments in agriculture, Zavitz and Squirell.....	31
[Fertilizer tests on swamp soils], Harcourt.....	32
[Adaptation experiments], Hampton.....	32
[Fertilizer and variety tests], Johnston.....	32
Supplementary pasture crops, Fisher and King.....	32
[Chemical and physical observations on Eritrea cereals], Manetti.....	32
Trials with grains and legumes for feeding purposes, 1899-1908, Hansen.....	32
Eighteen years' culture trials with root crops, Helweg.....	33
The agave, Michotte.....	33
Soils of the prairie regions of Alabama and Mississippi and use for alfalfa.....	33
How to grow alfalfa, Wiancko and Fisher.....	33
Genetic studies with the beet, Kajanus.....	33
A new plant fiber, Zimmermann.....	33
Local fertilizer experiments with cotton in South Alabama, 1911, Duggar et al.....	33
Local fertilizer experiments with cotton in North Alabama, 1911, Duggar et al.....	34
Cotton culture in North Carolina.....	34
Heading off boll weevil panic, Hinds.....	34
British cotton growing, Reed.....	34
Seed selection series. I, Broach cotton, Main.....	35
Sakellaridis cotton.....	35
[Cotton tests at the botanical garden of Palermo], Bozzi.....	35
Fertilizing ingredients in Danish hay crops, Kristensen.....	35
A note on onion couch, Underwood.....	35
Potatoes at Wisley, 1911.....	35
Six years' potato variety tests at Sindlingen, Adlung.....	35
A new potato.....	35
The thornless prickly pears, Griffiths.....	35
[Advice on prickly pear destruction].....	36
San hemp ( <i>Crotolaria juncea</i> ), Pátzil.....	36
Grain-sorghum production in San Antonio region of Texas, Ball and Hastings.....	36
Observations on the early flowering of the sugar beet, Munerati.....	36
Sweet clover, Westgate and Vinall.....	37
The culture of cigar leaf tobacco in Texas, Olson.....	37
Cultural tests of Herzegovina tobacco in Italy, Abbate.....	37
Water content of soil, nitrogen fertilization, and development of wheat, Meyer.....	38
Report of the Danish seed control station, 1910-11, Dorph-Petersen.....	39
[Tests of Bombay seeds], I, Mehta.....	39

## HORTICULTURE.

	Page.
Report on the government horticultural gardens, Lucknow, 1911, Davies.....	39
Report of fruit branch of department of agriculture, Ontario, Hodgetts et al. . .	39
Return of inspections of fruit and vegetables for 1911, Scriven.....	39
Spraying to control insects and fungus diseases affecting the apple, Scott.....	39
Orchard spray calendar, Richards.....	39
Lime-sulphur wash, Caesar.....	39
Valencia melon industry, Frazer, jr.....	39
Onions, McMeans.....	39
The pear and how to grow it, Brackett.....	40
The plums of New York, Hedrick et al.....	40
Report on orcharding and the wine industry, Brönnle.....	40
Grape culture, Farrar.....	40
The family strawberry patch and the way to make it a success, Boulton. . . . .	40
Roselle, its cultivation and uses, Wester.....	40
The Sour orange bud as a remedy for gummosis of citrus trees, Savastano.....	40
English walnuts, Allen.....	41
Making a lawn, Doogue.....	41
Amateur gardencraft, Rexford.....	41
Garden profits, Seymour.....	41
One hundred and fifty small gardens, Hampel.....	41
Let's make a flower garden, Verbeck.....	41
Orchids, O'Brien.....	41
Carnations and pinks, Cook, Douglas, and McLeod.....	41

## FORESTRY.

The elements of British forestry, Nisbet.....	41
Forestry for woodmen, Hanson.....	41
Wood and forest, Noyes.....	42
On forest types, Cajander.....	42
Experiments on the periodicity of some tropical trees, Dingler.....	42
On the periodicity of central European deciduous trees in Ceylon, Dingler.....	43
Strength, elasticity, and other properties of New South Wales timbers, Warren.	43
<i>Iveea brasiliensis</i> , Vernet.....	43
Anatomy of <i>I. brasiliensis</i> and <i>Manihot glaziovii</i> as to tapping, Arens.....	44
An irrigation method for tapping <i>Iveea</i> , Wurth.....	44
[Tapping experiments].....	44
On the coagulation of the latexes of some Euphorbias, Zimmermann.....	44
On heath burning for reforestation, Wibeck.....	44
A new sowing method in the mountains, Hauenstein.....	44
The Spranz seed sower, Schinzinger.....	44
Forest administration in Baluchistan for 1910-11, Mulraj and Dobbs.....	44

## DISEASES OF PLANTS.

Bacteria in relation to plant diseases, II, Smith.....	44
[Notes on plant diseases and their control], Russell.....	45
Some new or little-known plant diseases in Britain, Chittenden.....	45
Physalosporina, a new genus of Pyrenomycetes, Woronichin.....	46
New studies on Plasmodiophoraceæ, Maire and Tison.....	46
Scleropycnis, a new generic type, Sydow.....	46
A culture study of <i>Hyalospora polypodii</i> , Dietel.....	46
Parasitism of Nectria and Fusicladium, Voges.....	46
Infection studies with Peronospora, von Istvanffi and Palinkas.....	47
The infection of forage grasses by ergot, Gain.....	47
The use of iron sulphate for the control of the rust of plants, Fuschini.....	47
A practical view of root rot of beets, Briem.....	47
Rice blight, Collier.....	47
Preliminary study of the red rot of sugar cane, Kulkarni.....	48
The life history of the plum rust in England, Brooks.....	48
Experiments on the control of chlorosis of fruit trees, Rivière and Bailhache.....	48
Resistance to chlorosis, Verneuil and Lafond.....	49
Infection of grapes, by downy mildew, Krankoff.....	49
Conditions necessary for appearance of downy mildew, Ravaz and Verge.....	49
Experiments in treatment of grapevine mildew in Bombay Presidency, Burns. .	49
Relation of meteorological conditions to mulberry diseases, Arnaud and Lafont.	49

	Page.
Banana diseases, Fawcett.....	50
The Panama disease of the Gros Michel banana in Surinam, Drost.....	50
The banana disease.....	50
Die-back or exanthema of citrus trees, Essig.....	50
The withertip disease in Florida, Rolfs.....	50
New fungi occurring on orange leaves, Rehm.....	50
Notes on <i>Scleroplea aurantiorum</i> and <i>Mycosphaerella lageniformis</i> , Metz.....	50
A new <i>Mycosphaerella</i> from Saxony, Krieger.....	51
Mycological notes, von Hühnel.....	51
The slime disease of <i>Cyathea medullaris</i> , Sorauer.....	51
The Japanese chestnut at the experiment station at Lindsøis, Prunet.....	51
A disease of the beech, Magnus.....	51
Fungus galls on the beech, Möbius.....	51

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

A history of British mammals, Barrett-Hamilton.....	51
Mammals of western Montana in relation to spotted fever, Birdseye.....	52
Analysis of 87 fecal examinations of sheep dogs for parasitism, Foster.....	52
A new species of trematode from the muskrat, Barker and Laughlin.....	52
Microbes killing mice and rats, Voytkovich and Kolenev.....	52
Raticide—Azoa, Mereshkowsky.....	52
The food of birds of India, Mason and Maxwell-Lefroy.....	52
Chronology and index of American game protection, 1776-1911, Palmer.....	52
Physiology and morphology of the digestive apparatus of insects, Schlüter.....	53
Insect pest survey, Russell.....	53
Farmers' foes and their remedies.....	53
Insect pests in the West Indies in 1911.....	53
Insect notes for the year 1910-11, Guppy.....	53
Miscellaneous notes, Urich.....	53
[Destructive insects, 1910].....	53
Report of the entomological section of the Wellcome Laboratories, King.....	53
Suppression of the cotton white scale in Piura, Townsend.....	54
Insect pests of jute, Dutt.....	54
The enemies of rye, Noel.....	54
Fruit flies and other insects attacking fruits in New South Wales, Gurney.....	54
New control methods for the pear thrips and peach tree borer, Morris.....	54

# EXPERIMENT STATION RECORD.

VOL. XXVII.

JULY, 1912.

No. 1.

One of the significant educational developments of recent years has been the increasing recognition accorded to instruction in home economics. Although the term itself was unfamiliar a generation ago, at the present time home economics courses are being offered in this country in more than twelve hundred institutions, of which over two hundred are colleges and normal schools. Thirty-five of the land-grant colleges for white students are among the number, and twenty-seven of these offer four-year courses leading to degrees. Extension work has likewise been well organized in many of the States, largely with a view to reaching the women on the farm. In short, home economics instruction is already emerging from the pioneer stage and becoming an accepted factor in American education.

One of the principal obstacles which educators are encountering in their efforts to reduce the subject to sound pedagogical form is the comparatively retarded development of experimental work. It is well recognized that, as is the case with agriculture and other composite branches of learning, home economics is largely a specific application of the principles of chemistry, bacteriology, physics, and other sciences; but, as is also the case with agriculture, there are required to make it most effective special investigations and experiments, made from the standpoint of those who appreciate the needs and use to be made of such information.

Considering home economics as including the economic, sanitary, and esthetic aspects of food, clothing, and shelter as connected with their selection, preparation, and use by the family in the home or by other groups of people, it is a matter of everyday knowledge that many of its practical applications are still largely governed by rule-of-thumb or by tradition. For example, the laws of heat are well understood in the scientific world, but their application to cookery, food preservation, or the heating of houses needs far more investigation than it has thus far received. The present is preeminently the era of machinery, but the improvement of household appliances has

been left almost entirely to commercial exploitation, and progress has admittedly lagged far behind achievements in the factory and on the farm. Yet if there are to be reliable comparisons of the merits of different foods or textiles, or of different labor-saving or sanitary devices, there must be scientific tests by those familiar with the housekeeper's needs and competent to work out her problems.

The need of these studies is becoming the more imperative because of the increasing complexities of modern life. It is even more important now than it was a few years ago that there should be a scientific basis for instruction on how food materials can be best utilized in family diets, how houses should be constructed, furnished, and managed, and what materials are most suited for clothing, because of late years there has been less and less opportunity to acquire experience in such matters in the home itself. Two or three generations ago each home, and especially each rural home, was practically self-sufficient, producing not only its own food supply, but, to a certain extent, its own clothing, and constructing its buildings in such a simple way that any intelligent and experienced laborer could understand the principles involved. Now, however, a great many branches of work which were formerly home industries have been taken over by factories or by specialized workers, and there is no longer the opportunity to learn about them by practical trials in the home. In many cases such knowledge as is available is still, to a certain extent, handed down in an empirical way from mother to daughter, but in many others it would soon die out entirely did not schools or other educational agencies supply it, and these must acquire exact knowledge before they can transmit it.

It is true that many of the problems encountered are more or less isolated in application, and that much can be accomplished by individual initiative within the home. But it is as unreasonable to look to the farmer's wife for progress along technical lines, as to rely on the farmer to work out the fundamental principles of his art. As is pointed out by a recent writer on the subject, such knowledge as the housekeeper has "is in reality a by-product of a vast number of unrecorded and half-observed events. For the more exact and vastly more economical gathering of knowledge, by methods known to the laboratory, the housewife lacks the training and the outfit, especially the instruments of precision. Above all, she presides not over a laboratory, products of which are considered of no value except for teaching purposes, but over a factory the output of which—good food, clean and attractive rooms, suitable clothing, and all the rest—must not fail. By any methods known to her, usually those she has inherited, she must bring some semblance of these results to pass, and that daily."

Just as the trained experimenter was needed for the conversion of agriculture from a traditional to a scientific basis, all that relates to hygiene and household methods and the host of related questions demands careful study by experts having proper equipment for the undertaking.

Fortunately the dependence of home economics instruction upon research is becoming generally understood, and the belief that house-keeping is largely a matter of inspiration and feminine intuition, with no need of an accumulated store of information to draw upon, is rapidly giving way to the modern view that "a knowledge of house-keeping is not a matter of sex but of science." Nearly fifteen years ago the Secretary of Agriculture, in the Yearbook for 1897, pointed out that "the teachers of domestic science are not content to follow a dull routine of household drudgery in their teaching. They are appealing to the scientist and specialist in lines which touch the home life to explain the principles on which home practices should rest, and to show them how intelligent taste and skill can make the home a pleasant place to live in, and how scientific knowledge can enable the home-keeper to maintain the health and generally promote the physical well-being of those committed to her charge. Some progress has been made in formulating the replies which science is now able to give to inquiries relating to domestic science, and in undertaking investigations with a view to greatly broadening our knowledge of these matters in the days to come."

In the interval which has elapsed since these words were written much additional attention to research in problems affecting the home has been given, to some extent by home economic workers themselves and even more largely by scientists in associated lines. Agriculture in particular has contributed most valuable assistance, the community of interests between the production of food supplies, textiles, and other farm products and their utilization within the home being generally recognized.

Most of the agricultural experiment stations have from time to time studied problems which have to do with the handling, storing, and marketing of foods, while many have had to deal with food and drug inspection. They have also studied many technical as well as practical problems of milling and dairying, and other problems which pertain to the home as distinguished from the farm as an industrial enterprise. Of such work may be mentioned studies of the composition and digestibility of foods, numerous studies of cooking processes and of canning, dietary studies, the improvement in quality of cotton, flax, and wool, studies of household equipment and conveniences, and the cost of board for laborers on farms.

An important service has also been rendered by the engineering experiment stations established at several of the land-grant institu-

tions. Comparisons of different illuminants and fuels, and studies of sewage disposal plants and of building materials, may be cited as types of the work already undertaken.

It is well known that the Department of Agriculture has made a large number of contributions, the activities of nearly every bureau containing much of interest. The intimate connection of much of the work of the Bureau of Chemistry, the Bureau of Animal Industry, and the Bureau of Plant Industry is obvious, but there may also be mentioned the studies of household insects in the Bureau of Entomology, the utilization of woods by the Forest Service, some of the economic studies of the Bureau of Statistics, and a study in the relation of high altitude to cookery reported by the Weather Bureau. The nutrition investigations of this Office are, of course, accepted as fundamental by home economics educators, and the publications issued as part of the work are widely utilized as texts.

The contributions of home economics workers themselves have been numerous and meritorious, especially in view of the comparative newness of the subject and the lack of organized research agencies. The attention which is being concentrated on the preparation of research workers is yielding results of much promise, and the list of additions to knowledge in the form of theses for advanced degrees is each year becoming more impressive.

Contributions from the more mature workers actively engaged in instruction duties are even yet relatively few. This of course is unfortunate, since their qualifications and experience would seem to promise results of exceptional value. It is not, however, particularly surprising, for as was recently pointed out, "under present conditions, the task of the college teacher of home economics is a very difficult and complicated one. By study and research she must assemble and enlarge a new body of knowledge and give it pedagogical form. She must prepare manuals, text-books, apparatus, and illustrative material in this new subject. . . . Besides giving sound and thorough instruction to her college students, she must do a large amount of propaganda work to secure the general recognition of home economics in the elementary and secondary schools, and all she can of that broader extension work by which the multitudes of untrained women in the homes are to be encouraged and inspired."

Notwithstanding these difficulties, to which may be added those imposed by an absence of funds for research and often of equipment, the uncertainties as to the publication of results, and the lack of many other advantages enjoyed by a regularly organized research institution, it is believed that there are many opportunities for adding to the store of knowledge by the use of existing facilities. If home economics embodies, as has been stated, "the utilization of

all the resources of science to improve the home life," then the chemist, the physicist, and the economist may each be expected to contribute his share. Studies corresponding, for instance, to those recently reported from the department of bacteriology of the University of Wisconsin on the sanitary value of vacuum cleaners and on the preservative action of various spices, would doubtless occur to many a worker in these related sciences, and if brought to completion would be assured of immediate application.

Oftentimes, too, investigations already under way at the experiment stations may be legitimately extended to throw light on those phases of particular interest to the home. In other cases there may be cooperation with home economics departments to their mutual advantage. A study of this type was completed some time ago at the University of Missouri. Here the meats produced under controlled conditions in connection with nutrition studies of the station were utilized by a graduate student in home economics for an inquiry as to the relative economy of various cuts of beef.

An interesting development of recent years has been the establishment of commercial "housekeeping experiment stations." These have thus far given particular attention to household appliances, but the idea could doubtless be more widely extended.

The responsibility for real progress in research, however, must rest largely with the home economics departments. Whatever the assistance rendered by other agencies, the upbuilding of a distinctive body of home economics knowledge must come mainly from investigations by the home economics workers themselves, rather than through the mere adaptations of either traditional methods or "borrowed science." It is well known that this has already been the experience in agriculture, and the close analogy between the two studies warrants the prediction that the future of home economics instruction depends very largely upon its establishment on a sound scientific foundation by those to whom its development has been specifically intrusted.

Doubtless in many cases the undertaking of comprehensive investigations by home economics instructors is impracticable under present conditions, but as in the early days of agricultural instruction, there are a host of smaller projects awaiting and needing solution for which opportunity might be found. For instance, in the field of textiles, there may be cited studies of the relative durability of different fabrics as affected by such controllable conditions as the kind of material, its thickness, and its closeness of weave; the testing of various solvents in removing stains from fabrics; and the comparison of soaps and detergents in different waters and temperatures. There might well be additional studies of the comparative cost of household

fuels and illuminants, of the use of nonconducting materials in stoves and other cooking utensils, and of the solubility of kitchen ware in different waters, fruit acids, and other liquids. The preparation of systems of household accounts and the investigation of the lessening of the time requirements of household operations, the actual loss incurred by the purchase of supplies in uneconomical quantities and the incomplete utilization of "left overs," are other examples, such as will readily suggest themselves to the thoughtful observer. Many of these studies might readily be carried through during the long summer vacation, and others demand regular attention rather than large amounts of time.

In many of these cases not the least of the benefits to be secured would be the stimulation of the research spirit of the teacher, for the generally accepted opinion of President Jordan of Leland Stanford University that "no one can be a great teacher without the spirit of research; without this he lags behind the progress of knowledge and his mental equipment becomes second hand," is as applicable to home economics as to other subjects of instruction. There is also the same broadening and stimulating effect on advanced students in home economics as on those in other lines.

The increasing attention which is being devoted to the more thorough training of prospective teachers in research methods is a recent development which augurs well for the future. The steadily improving facilities for graduate study, the numerous summer schools now available, and in particular the inspiration of the Graduate School of Home Economics, which has just completed its fourth session at the Michigan State Agricultural College in close association with the Graduate School of Agriculture, are destined to add greatly to the ultimate efficiency of home economics instruction and experimentation. Once the inculcation of the spirit of research into the investigators of to-morrow can be accomplished, the establishment of home economics as a well-defined science will be assured, and its consistent development may be confidently awaited.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

A study of humus in Hawaiian soils, W. P. KELLEY and W. McGEORGE (*Hawaii Sta. Press Bul. 33, pp. 23, fig. 1*).—While studying Hawaiian soils as regards their humus content it was found that those soils obtained from the upper islands, which had a varied physical structure and in some instances a high percentage of clay and silt, gave unreliable results with the official method. As the clay in these soils could not be removed by any other means than by using the Cameron-Breazeale-Alway clay filter method (*E. S. R., 24, p. 9*), the authors made an effort to overcome the difficulties which attend its use.

This was done by drawing the solution through the filter in the reverse direction from that usually employed. For the compression chamber was substituted an ordinary suction pump. "The tube of glazed porcelain, attached to the lower end of an 8-in. Pasteur-Chamberland tube, was broken off so as to leave this end of the tube open; then the tube was inserted into the upper opening of a bell jar, such as is used for filtering with suction, in a manner similar to that employed in the use of a Gooch. A large part of the tube was allowed to extend into the filtering jar and the connection was made air-tight by means of a short piece of Gooch tubing or a rubber stopper. It was also found desirable to coat the upper portion of the tube with paraffin so as to prevent the passage of the solution except in the lower half of the filter tube, otherwise the solution will pass down the side of the bell jar.

"A 50 cc. aliquot of humus solution (the preliminary extractions with hydrochloric acid were made by digesting 10 gm. of soil in 200 cc. of fifth-normal hydrochloric acid at ordinary laboratory temperature for 5 hours, filtering, and washing free from acid with distilled water, as outlined by Fraps in his directions for cooperative study of humus determination for the Association of Official Agricultural Chemists, May, 1911), which represented 1 gm. of soil, was drawn through the tube by means of reduced pressure, the filtrate being collected in a short cylinder. After the entire aliquot was drawn through, a 4 per cent solution of ammonia was then passed through so long as it showed any color. Usually about 200 cc. was required. In no instance was it found necessary to use more than 250 cc. The filtrate and washings were then evaporated to dryness and the determinations completed as usual.

"Some difficulty was experienced in completely removing the clay in certain soils. There was found to be considerable difference in different tubes in this respect. Some filters will remove all clay, while others seem to allow a small amount of the most finely divided clay to pass through. . . .

"The time required to complete a filtration was found to be about 3½ hours, and by arranging a number of filtering jars in a series an ordinary Richardson pump will provide suction for at least 3 filters, and with close-fitting con-

nections it is probably possible to operate  $\frac{1}{2}$  doz. filters with one pump. In any event, at least  $\frac{1}{2}$  doz. solutions can be filtered in one day by this apparatus."

"After each filtration the tube should be washed out. A test-tube brush was found to be serviceable in removing the clay from the inner walls of the filter tube."

The results obtained show that the modified clay filter method yields higher results than either the Hilgard, Mooers-Hampton, or the Cameron-Breazeale method, and lower results than the Rather and official methods. The latter 2 methods, however, could not be relied upon as far as Hawaiian soils are concerned. The Rather method in most instances did not bring about a coagulation of the clay. On the other hand, although the results obtained with the Mooers-Hampton, Hilgard, and Cameron-Breazeale methods at times furnished concordant results, on the whole they were found to be in disagreement.

It was furthermore noted that as much as 4 gm. of ammonium carbonate per 100 cc. of soil extract was necessary to effect a complete coagulation of the clay with the Rather, Rather modified, and the modified clay filter methods. In some instances, however, a partial precipitation of humus also took place with the Rather methods. Organic matter was precipitated with all the methods. The fundamental reason for the differences in coagulability of the clays seems to lie in the fact that the clays under examination were different in composition. The uncoagulated suspensions were always found to contain relatively more iron and correspondingly less aluminum. The iron and aluminum in such solutions were found to be present in about the proportions necessary for the formation of a double silicate.

**The detection of nitrates with diphenylamin, H. CARON** (*Ann. Chim. Analyt.*, 16 (1911), No. 6, pp. 211-215; *abs. in Chem. Zentbl.*, 1911, II, No. 6, p. 390).—The diphenylamin reaction for nitrates was found to depend upon the concentration of the diphenylamin and sulphuric acid and the temperature. The reaction was more pronounced if the diphenylamin was present in small quantities and concentrated sulphuric acid was used in the test.

The test is best conducted by adding to 1 volume of the solution containing the nitrate  $2\frac{1}{2}$  volumes of a 0.002 per cent diphenylamin solution in concentrated sulphuric acid. The presence of hydrochloric acid or chlorids will not affect the reaction if concentrated sulphuric acid is used. If, however, diluted reagents are employed the presence of a drop of hydrochloric acid will render the reaction more sensitive. Glycerin, acetone, carbohydrates, salicylic acid, phenol, etc., destroy the intensity of the reaction more or less, particularly if the reagent employed has been prepared with concentrated sulphuric acid. When these substances are present the reagent must be prepared with hydrochloric acid.

**The determination of nitrogen in commercial ammoniates, P. RUDNICK ET AL.** (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 10, p. 783).—This is the second report of the committee on nitrogen, which was appointed by the division of fertilizer chemists of the American Chemical Society. It contains the reports of 15 analysts who determined the nitrate nitrogen according to the modified Gunning-Kjeldahl method and the moisture, using 2 gm. samples of fertilizer.

A wide range in the results on both moisture and nitrogen was reported, and no definite conclusions could be drawn. Local conditions of manipulation and reagents were deemed probably responsible for as much variation as any other factor. A further study of the subject with a view to the establishment of a standard sample is recommended.

**An apparatus for preparing ammonium citrate solution, G. VECCHI** (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 1, pp. 56, 57, fig. 1).—A simple apparatus, which

can easily be constructed in the laboratory, for preparing as much as 5 liters of ammonium citrate solution at one time is described.

A critical study of methods for determining the hardness of natural waters, J. M. SILBER (*Arch. Hyg.*, 73 (1911), No. 2, pp. 171-182).—Wartha's method<sup>1</sup> for determining the transitory hardness, when modified according to the author's specifications, yields good results, but otherwise leads to error.

In regard to the determination of proteins and the digestion of protein by pepsin, F. WESTHAUSSER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 72 (1911), No. 5-6, pp. 363-373; *abs. in Zentbl. Physiol.*, 25 (1911), No. 16, p. 673).—Determinations of proteins by Stutzer's method and by precipitation with tannin generally yield the same result. The methods can also be used for separating protein from amid nitrogen. On the other hand, varying results were obtained when the methods were used for separating the cleavage products resulting from the action of pepsin on protein. Identical results were obtained in fecal analyses.

The measurement of the oxidase content of plant juices, H. H. BUNZEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 238, pp. 49, pls. 2, figs. 9; *Jour. Amer. Chem. Soc.*, 34 (1912), No. 3, pp. 303-316, figs. 2).—Inasmuch as practically all of the tests heretofore reported for studying the activity of plant oxidases are of a more or less qualitative nature, a new method is described in which the oxygen is absorbed by pyrogallol through the agency of the plant juice, and the carbon dioxide developed is determined with sodium hydroxide. The oxygen absorbed is noted by means of the manometer.

The apparatus employed in the method is as follows: (a) A compact oxidase apparatus constructed entirely of glass, and with which it is possible to conduct the entire reaction, that is, oxygen and carbon dioxide absorption in the same apparatus (the apparatus also has connected with it a graduated apparatus for adding the reagents and the plant juice without disconnecting in any way); (b) a compact titration apparatus for determining the amount of carbon dioxide absorbed by the sodium hydrate solution; and (c) an electrically heated and controlled thermostat for conducting the oxidase reactions under uniform temperatures and conditions. The thermostat also contains a shaking device.

Some tests with the apparatus and potato peelings for furnishing the oxidase preparation, and some with normal beet leaves and others affected with curly top disease, are recorded, and which show that the apparatus furnishes concordant results.

On the determination of dry matter in roots, H. GOLDSCHMIDT (*Malkeritid.*, 25 (1912), Nos. 1, pp. 12-15; 2, pp. 33-38; 3, pp. 63-70, figs. 4).—A new method of determining the dry matter content of roots is described, and the apparatus used is illustrated. Samples weighing about  $\frac{1}{2}$  kg. are ground and dried in a specially constructed drying apparatus at steam heat for a period of from 48 to 72 hours, according to the number of samples being dried. Comparative results obtained with samples of different sizes are reported, showing a general agreement to within a few hundredths of 1 per cent.

A study of the carbohydrates in the prickly pear and its fruits, R. F. HARE (*New Mexico Sta. Bul.* 80, pp. 30).—This is a continuation of previous work (E. S. R., 19, p. 65). Among other objects, this investigation was to determine the composition of the mucilage, which this plant contains during its cycle of growth but which disappears at the ripening period, with a view of ascertaining its function and its possible economic uses.

"The juice of the ripe fruit contains 1.57 per cent of pentosans and only traces of galactan. When previously precipitated with lead acetate, the juice

<sup>1</sup> *Ztschr. Angew. Chem.*, 15 (1902), No. 9, p. 198.

gave the anilin acetate reaction for pentose, but none for galactose. The presence of fructose and glucose in considerable amounts was quite definitely established by several reactions characteristic of these sugars.

"The dried mucilage of the prickly pear, when separated by precipitation with alcohol from a 2 per cent solution, contained 15 per cent of galactan, 31 per cent of pentosan, and 12 per cent of ash.

"The mucilage could not be separated completely from cell fragments, starch, crystals of calcium oxalate, and other solid particles that caused opalescence and turbidity. A dilute solution with 1.5 per cent of total soluble solid matter, rendered fairly clear by repeated filtration through silk, had no effect on polarized light. This was true of all the solutions of mucilage obtained in this work, both before and after subjecting them to acid hydrolysis. . . .

"Hydrolysis of the mucilage by digestion for several hours with 1.25 per cent sulphuric acid solution produced a sugar that had properties similar to arabinose. When its osazone was formed, oily globules rose to the surface. The precipitate was darker than glucosazone, readily soluble in hot water, and melted at near 160°.

"A 95 per cent alcoholic extract of the dried stems, previously treated with ether, contained a sugar with specific rotations made on three separate solutions of -6.6°, -8.25°, and -7.1°. The osazone produced from this sugar had properties similar to those of glucosazone. These results indicate the presence of mixtures of glucose and fructose in this extract.

"A 60 per cent alcoholic extract of the dried stems contained a substance apparently intermediate in character between mucilage and sugars. It did not reduce Fehling solution before hydrolysis, but was very readily hydrolyzed by dilute acids. Alcohol stronger than 60 per cent reprecipitated this material as a flocculent mass, quite different in appearance and properties from the precipitate of the mucilage with alcohol. The precipitate was readily soluble in water, but its solution was not mucilaginous. When hydrolyzed it gave a plus rotation to polarized light.

"The coloring matter can be concentrated and made into a marketable product, of value for coloring certain foods, by first removing mucilages and gums with alcohol, and precipitating the pigment from the filtrate with acetone.

"The pigment is evidently a glucosid. When separated from the juice with alcohol and acetone, and then precipitated with lead acetate, the coloring matter liberated by sulphuric acid gave a sugar on hydrolysis, with properties similar to those of glucose.

"The lead salt produced by precipitating the purified pigment with lead acetate contains 61.42 per cent lead."

A solution of the gum, while very viscous, possesses only a very low degree of adhesiveness.

**The analysis and composition of grapes, R. BRUNET (*Rev. Vit.*, 37 (1912), No. 9/2, pp. 15-20).**—This is a discussion in regard to the variations in the chemical composition of grapes during the cycle of growth. It includes analyses of the stems, skin, pulp, and seeds.

**The composition of the apple as affected by irrigation, C. E. BRADLEY (*Jour. Indus. and Eugin. Chem.*, 3 (1911) No. 7, pp. 496, 497).**—Apples which were grown on irrigated soil were found to be somewhat higher in moisture, higher in sugar, and lower in solids than the samples which were obtained from the dry check plots. The apples were also larger, but the individual apples from a given space showed very little variation among themselves. The protein content of the peelings showed an average of 0.7 per cent and that of the edible portion only 0.2 per cent. Traces of starch were present in the samples tested.

Investigations in regard to the composition of pear and apple seeds, P. HUBER (*Landw. Vers. Stat.*, 75 (1911), No. 5-6, pp. 443-461).—A qualitative and quantitative study of pear and apple seeds, with particular reference to the oil, proteins, and carbohydrates which they contain, is summarized below:

Composition of pear and apple seeds.

	Pears (Theiler).			Pears (Reinholz).			Apples (Uster).		
	Decorticated seeds.	Hulls.	Whole seeds.	Decorticated seeds.	Hulls.	Whole seeds.	Decorticated seeds.	Hulls.	Whole seeds.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Weight relation of decorticated seeds and hulls:

The hydrocyanic acid content of some seed and stone fruits, P. HUBER (*Landw. Vers. Stat.*, 75 (1911), No. 5-6, pp. 462-482).—The seeds of most of the pears which grow in Switzerland contain practically no amygdalin (less than 1 mg. in 100 gm.), but traces of emulsin-like enzymes, the activity of which is 100 times less than that of those present in sweet almonds. Apple seeds, on the other hand, contain from 0.62 to 1.38 per cent of amygdalin, calculated to dry substance, which corresponds to from 0.037 to 0.082 per cent of hydrocyanic acid. Sweet apple seeds (Uster) contained the least of those examined, while Holz contained the most. Apple-quince seed contained from 1.18 to 1.23 per cent of amygdalin, pear-quince seeds from 1.18 to 1.24 per cent, and the seeds of the Japanese quince (*Cydonia japonica*) 2.29 per cent.

Stones of the following fruits were also examined and showed amygdalin contents as follows: Black cherries (*Prunus avium*) 1.72 per cent, blue plums (*P. insiticia*) 4.33 per cent, plum (Reineclaude) 5.03 per cent, German prunes (*P. domestica*) 2.52 per cent, Welch prunes (*P. domestica*) 4.32 per cent,

apricots (*P. armeniaca*) 0.11 per cent, luizet (*P. armeniaca*) 0.29 per cent, and peaches (*P. persica*) 2.63 per cent.

By macerating the ground seeds for 3 hours in water, and then distilling, fairly constant values can be obtained for hydrocyanic acid having its origin from the amygdalin or other glucosids through the interaction of emulsin contained in either the stones or seeds of fruits. About one-ninth of the hydrocyanic acid which can be theoretically obtained is converted into formic acid.

**Analysis of mustard flour**, A. DOMERGUE (*Jour. Pharm. et Chim.*, 7. ser., 4 (1911), No. 11, pp. 494-496, fig. 1; abs. in *Analyst*, 37 (1912), No. 431, pp. 55, 56).—On estimating the amount of mustard oil in mustard flour it is necessary to keep the distilling vapors from coming in contact with the rubber connections. Accordingly, the author uses an apparatus in which one end of the condenser is connected with the flask by means of a ground glass stopper, while the other end is bent downward at a right angle and dips into a graduated cylinder. The distillate is collected according to Lenormand's method, 20 cc. of deci-normal silver nitrate solution being added, and the solution made up to a bulk of 100 cc. The rest of the procedure is the usual one.

Commercial mustards usually contain from 0.2 to 0.9 per cent of oil. The French codex requires 0.7 per cent as a minimum for black mustard seed.

**A recently discovered bacterial decomposition of sucrose**, W. L. OWEN (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 7, pp. 481-486).—Previously noted from another source (E. S. R., 25, p. 110).

**A new method for estimating sugar**, F. VON FILLINGER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 22 (1911), No. 10, pp. 605-607, fig. 1; abs. in *Analyst*, 37 (1912), No. 431, pp. 63, 64; *Ztschr. Angew. Chem.*, 25 (1912), No. 9, p. 431).—Three solutions are required: (a) 250 gm. of potassium sulphocyanate, 250 gm. of potassium carbonate, and 25 gm. of potassium bicarbonate in 1 liter; (b) 4.278 gm. of copper sulphate in a liter; (c) 200 gm. of potassium sulphocyanate, 250 gm. of potassium carbonate, 50 gm. of potassium bicarbonate, and 10.42 gm. of copper sulphate in a liter, and filtered. In the flask (vented) described 20 cc. of each of the solutions (a) and (b) are placed and brought up to the boiling point, and from the burette the sugar solution is added until the color is discharged. Solution (c) serves as a preliminary test to determine the concentration of the sugar solution approximately.

**Extraction of grains and cattle foods for the determination of sugars: A comparison of the alcohol and the sodium carbonate digestions**, A. H. BRYAN, A. GIVEN, and M. N. STRAUCHN (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 7, pp. 486-497).—Previously noted from another source (E. S. R., 25 p. 110).

**Detection of salicylic acid**, H. C. SHEPHERD and A. GROSS (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 7, pp. 492, 493; abs. in *Ztschr. Angew. Chem.*, 25 (1912), No. 9, p. 431).—To the solution to be tested from 4 to 5 drops of a 10 per cent potassium or sodium nitrite solution, from 4 to 5 drops of a 50 per cent acetic acid solution, and 1 drop of a 1 per cent copper sulphate solution are added. After each addition of the foregoing reagents the mixture is shaken. The mixture is then placed in a boiling water bath for 45 minutes, cooled, and the red color obtained when as little as from 0.005 to 0.01 mg. of salicylic acid is present noted against a white background. Where larger amounts of salicylic acid are present a stronger solution of copper sulphate is necessary.

**In regard to the differences in the cleavage of casein, paracasein, and calcium paracaseinate of cow's and goat's milk by trypsin and pepsin**, J. HÖSL (*Über Unterschiede in der tryptischen und peptischen Spaltung des Caseins, Paracaseins und des Paracaseinkalkes aus Kuh- und Ziegenmilch. Inaug. Diss.; Univ. Bern, 1910, pp. 31*).—Casein and paracasein from cow's milk in vitro were found to behave alike toward trypsin. Paracasein is cleaved more thoroughly

by pepsin-hydrochloric acid than casein. The casein and paracasein from goat's milk reacted in the same manner as those from cow's milk.

**Boiling test, alcohol test, and acidity degree of milk,** O. RAMMSTEDT (*Ztschr. Offentl. Chem.*, 17 (1911), Nos. 23, pp. 441-455; 24, pp. 467-471; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 9, p. 436).—No definite relation exists between the alcohol coagulation and the acidity of milk, but, on the other hand, the boiling, alcohol, and acid tests are of value as preliminary tests for milk hygienic work. Milk obtained under cleanly conditions has better keeping qualities than either pasteurized or raw market milks. The rennet, fermentation, catalase, reductase, and leucocyte tests are valuable in detecting impure milks.

**The guaiac test for distinguishing between raw and boiled milk,** K. SCHERN and W. SCHELLHASE (*Berlin. Tierärztl. Wchenschr.*, 27 (1911), No. 48, pp. 868, 869).—As all guaiac tinctures do not serve as reagents for distinguishing raw milk from boiled, the author proposes a formula for preparing a reagent which will give a positive intense blue coloration when raw milk is present. This formula consists of resin. guajaci 10 gm., guajacoli 10 gm., perhydrol (3 per cent) 1 drop, and absolute alcohol 80 gm. This is termed the guaiac-guaiacol test. The use of the test in foot-and-mouth disease and tuberculosis is also considered.

**Is the blue coloration obtained with tincture of guaiac an accurate indication that milk has not been boiled?** H. TEWES (*Molk. Ztg. [Hildesheim]*, 25 (1911), No. 79, pp. 1499, 1500).—If a brown color is obtained with the guaiac test, the milk in all probability has been boiled. If, on the contrary, a violet or blue coloration is obtained it is necessary first to determine whether some oxidizing agent or water has not been added to the milk. Boiled milk subsequently contaminated with bacteria or mill dust will also give a positive reaction.

**The Schardinger reaction for milk,** W. RULLMANN (*Biochem. Ztschr.*, 32 (1911), No. 5-6, pp. 446-452).—Milk containing micro-organisms and thermostable bodies and milk free from them decolorize together or alone Schardinger's methylene blue-formalin solution in a few minutes at temperatures varying from 45 to 50° C. The formaldehyde in the reagent may be replaced by an equivalent amount of formic acid, but the appearance of the reaction requires a much longer time. The reaction in sterilized milk with either methylene blue-formaldehyde solution, or methylene blue-formic acid solution is probably due to the presence of thermostable bodies. The age of the milk has no influence upon the reaction, providing of course that the milk remains sterile. If small amounts of sodium hydroxid, ammonium salts, and phosphates are added the reaction is accelerated, particularly if a little milk sugar is added at the same time. Milk sugar when added alone is inert. Increasing the temperature somewhat will also aid the acceleration of the reaction.

Raw, pasteurized, and sterilized milk, and milk which has been boiled for a certain time were found to behave differently as regards the time required for the decoloration of the reagent. This is probably due to the demineralization of the milk, which begins at +50°, the destruction of the enzym, which starts in at 65 to 69°, and the decomposition of the proteins, which is influenced by heat.

Contrary to Sames and Römer's findings (*J. S. R.*, 23, p. 709; 24, p. 412), the author never noted the absence of a positive reaction with milks which were retained in the udder longer than usual, or was there ever any absence of the reaction in the initial milk.

The Rothenfusser reaction was found to be very accurate, and to detect an addition of 1 part of raw milk to 1,000 parts of boiled milk. The Schardinger

method, however, which does not necessitate the preparation of a milk serum, can be given the preference for use in the milk bacteriological laboratory.

The catalase reaction for detecting milks coming from cows affected with mastitis, E. HUYNEN (*Ann. Méd. Vét.*, 60 (1911), No. 5, pp. 279-290, figs. 4).—This reaction is of value for detecting the milk obtained from mastitic cows. A milk of which 5 cc. will yield 1.5 cc. of oxygen (from 2 cc. of 1 per cent hydrogen peroxid solution) is to be regarded with suspicion.

The volatile acidity of gum tragacanth compared with that of Indian gum, W. O. EMERY (*U. S. Dept. Agr., Bur. Chem. Circ. 94*, pp. 5, fig. 1).—As the amount of volatile acid developed by samples of gum tragacanth is nearly 7.5 times less than that contained in Indian gum (*Sterculia wrens*), and that of both gums is relatively constant it is an easy matter to detect these gums, either alone or in a mixture. A method is described and results reported.

Determination of nicotin, G. BERTRAND and M. JAVILLIER (*Ann. Chim. Analyt.*, 16 (1911), No. 7, pp. 251-256; *abs. in Chem. Ztg.*, 35 (1911), No. 72, p. 657).—This is a study of the silicotungstic acid method devised by the authors, which was found to yield excellent results under varying conditions, particularly in the presence of ammonium salts. The determination of nicotin in the presence of pyridin may be made accurately by slightly modifying the procedure, as pyridin and its homologues are optically inactive and both pyridin and nicotin are precipitated by silicotungstic acid. The results compare well with those obtained by Schloesing's method, although slightly higher.

An electrically controlled constant-temperature water bath for the immersion refractometer, H. C. GORE (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 7, pp. 506, 507, figs. 2).—Previously noted from another source (E. S. R., 25, p. 311).

Mixing, stirring, and kneading, and the machines used for these purposes, H. FISCHER (*Mischen, Rühren, Kneten und die dazu verwendeten Maschinen. Leipsic, 1911, pp. 90, figs. 122; rev. in Amer. Chem. Jour.*, 47 (1912), No. 4, pp. 352, 353).—The book undertakes "to discuss the principles of the operations of mixing, stirring, and kneading as carried out in industrial chemical work, and to describe by diagrammatic sketches some of the leading forms of apparatus used, as far as this is necessary to show some applications of the principles."

International catalogue of scientific literature. D—Chemistry (*Internat. Cat. Sci. Lit.*, 8 (1908), pp. VIII+1067).—This issue deals with the literature received between December, 1908, and November, 1909.

Yearly report in regard to the progress made in agricultural chemistry, edited by T. DIETRICH (*Jahresber. Agr. Chem.*, 3. ser., 12 (1909), pp. XXXIV+545; 13 (1910), pp. XXXII+619).—These are the reports for the years 1909 and 1910, continuing previous work (E. S. R., 22, p. 311).

Report of the official agricultural chemical, physical, and analytical laboratories of Belgium, 1910 (*Raps. Sta. Chim. et Phys. Agr. et Labs. Anal. [Belgium]*, 1910, pp. 75).—This is a report of the directors of the various state laboratories in regard to work in progress, and the results of examining feeding stuffs, fertilizers, foods, sugar beets, industrial products, and miscellaneous samples. In some instances the methods of analysis used in the investigations are included.

Modern chemical technology, edited by O. DAMMER (*Chemische Technologie der Nahrungsmittel. Stuttgart, 1910-11, vols. 1, pp. XV+852, figs. 217; 2, pp. XIX+1065, figs. 508; 3, pp. XXIV+1049, figs. 402*).—This work, which has been written by 50 docents and practical men, embraces almost the entire field of chemical technology. The topics of interest to agriculture and agrotechny include paper, starch, dextrin, glucose, cane sugar, bread, wine, beer, alcohol, press yeast, utilization of waste yeast, vinegar, fats and oils, resins and balsams,

milk and dairy products, conserved fruits and vegetables, tannin, peat, water, and alkaloids.

These books are to be companion volumes to the author's handbook on chemical technology.

**Yearly reports in regard to the fermentation organisms, A. KOCH** (*Jahresber. Gärungs-Organ., 18 (1907), pp. VIII+684; 19 (1908), pp. VIII+676*).—These are the reports for 1907 and 1908 of the progress made in the field of the fermentation organisms.

**Manufacture of starch, F. REHWALD** (*Die Stärkefabrikation. Vienna and Leipzig, 1911, 4. ed. rev., pp. VII+302, figs. 87*).—This is a technological handbook giving methods for the manufacture of starch, dextrin, glucose, sirup, and sugar color.

## METEOROLOGY—WATER.

**The climate of Switzerland, J. MAURER, R. BILLWILLER, JR., and C. HESS** (*Das Klima der Schweiz. Frauenfeld, Switzerland, 1909, vol. 1, pp. VIII+302, pls. 5, figs. 9; 1910, vol. 2, pp. V+217*).—The climatic features of Switzerland as shown by observations extending over 37 years (1864-1900) are described.

**The influence of rain and of temperature of the air on cereal crops in the Governments of Saratov, Samara, and Tambov, S. KHARIZOMENOV** (*Selsk. Khoz. Vestnik Tugo-Vostok, 1911, No. 4-6; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 12 (1911, No. 6, pp. 927, 928; Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 3 (1912), No. 3, pp. 609, 610*).—From a comparison of meteorological conditions and crop yields during 25 years, the following conclusions are drawn:

"Increase of rain in winter is accompanied by a parallel increase in the crops; abundant rainfall in November, December, January, February, and March is beneficial to all cereals, but heavy rains in April are on the contrary very injurious to them. Increased rainfall in August, September, October, and April causes a decrease in the crops of spring cereals, while winter cereals and perennial forage plants are not harmed. The explanation of the good and bad effect of rain must be sought for in pedology and in vegetable physiology. The effect of capillary action is the principal cause of the damage wrought by rain. A detailed description is given of the movement of water in the soil during the different seasons of the year.

"In the district of Saratov, as the temperature is below the optimum in autumn and winter, and above in June and July, it follows that during both these seasons the nitrification processes are retarded and hindered."

**Precipitation in Havana in each month of the years 1859 to 1908, E. W. MÜLLER** (*Tropenpflanzer, 15 (1911), No. 12, pp. 678, 679*).—A table gives the monthly and yearly averages for this period. The annual mean for the 50 years is 1,234.8 mm. (48.6 in.) The driest month is March, with a 50-year average of 51.8 mm., the wettest June, with an average of 166 mm.

**Protection of Beaujolais against hail by electric barrages, J. PERRAUD** (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 33 (1912), No. 11, pp. 324-332*).—An account is given of the installation of the Beauchamp method (E. S. R., 22, p. 118) in this region.

**Water powers of North Carolina (N. C. Geol. and Econ. Survey Bul. 20, 1911, pp. 383, pls. 2, figs. 2)**.—This bulletin has been prepared under the direction of M. O. Leighton and M. R. Hall of the U. S. Geological Survey. A large amount of data is presented relating to the flow and power of streams in North Carolina, including annual rainfall data, gage heights, and dis-

charge measurements. The topography of each stream basin and of the tributary drainage areas is described.

The data in general show that North Carolina has a large source of available water power both in the larger and the smaller streams. The "small power" streams may be found in all parts of the central and western portions of the State.

The origin and wholesomeness of the saline waters in the London Basin, J. C. THRESH (*Lancet* [London], 1912, I, No. 5, pp. 311, 315, 316).—This is a brief discussion of the results of examinations of waters derived from the chalk and Thanet sands under southeastern Essex, London, and other places, some of which contain as high as 70 grains per gallon of sodium chlorid and many average at least 50 grains per gallon. It is explained that these waters are derived from an admixture of sea water and chalk water altered by percolation through the Thanet sands. The sodium chlorid derived from the sea water remains unchanged while the calcium carbonate of the chalk water is converted into sodium carbonate. In spite of this unusual character, the waters are considered wholesome.

Purification tests of the water supply of Marseille, O. ARNAUD, C. FABRY, and MOITESSIER (*Off. Internat. Hyg. Pub.* [Paris], *Bul. Mens.*, 3 (1911), No. 12, pp. 2177-2215, figs. 8).—Seven processes used in these tests are described and the results obtained with them are discussed. The processes included chemical precipitation, filtration, and purification by means of ozone and ultraviolet rays. The best results from an economic standpoint were obtained with a system of filtration with submerged sand filters, although good results were obtained by ozonization and treatment with ultraviolet rays.

Utilization of sludge in England, L. BATLEY (*Municipal Jour. and Engin.*, 32 (1912), No. 13, p. 483).—It is stated that "the economical utilization of waste products generally has advanced further in England than in this country and the disposal of sewage sludge or pressed sewage cake has been receiving considerable attention there within the past few years. Various methods of disposal have been suggested with the object of so treating the sewage that the expense entailed may be, as far as possible, more than covered by the receipts obtained from the sale of the products. An additional inducement is the fact that the problem of disposal of sewage sludge is a very present one and is yearly becoming more urgent."

The methods employed by various towns in England are briefly described. At Bradford the sludge is rendered to remove the grease which is sold as "Yorkshire grease" for \$40 per ton. The filter press cake remaining after the extraction of the grease and containing about 40 per cent of moisture is dried and sold as a fertilizer base for \$2.50 per ton, finding "a large and increasing market at home, on the Continent, and in the United States." At Chorley the sludge is used with satisfactory results for the manufacture of gas.

At other works in this region the method generally followed is to press the sludge into cake, containing from 60 to 75 per cent of moisture, and to give it away to farmers in the immediate vicinity or use it to fill up low lying land. Although the material has from 3 to 4 times as much fertilizing value as ordinary farmyard manure, it is in such form that there is little demand for it from farmers, who in some cases are paid from 12 to 24 cts. per load to remove it.

At Manchester part of the sludge from the filter beds is dried and sold as a fertilizer for \$5 per ton, the demand being much greater than the supply. At Kingston-on-Thames the sludge is mixed with various materials, including alum, blood, and clay, dried, and sold as a fertilizer by a private company under the name of "native guano" for from \$15 to \$20 per ton. At Norwich "a plant

is now being erected for pressing and drying the sludge and for recovering the grease which forms about 30 per cent of the dry product; the dry residue, which contains about 3 per cent nitrogen, to be sold as a fertilizer." At Tadeaster arrangements are being made to handle the sewage in much the same way as is done at Bradford, "and the product has already been sold in advance for several years to come, to be exported to the United States."

At Leeds the sludge is used for the manufacture of ammonia gas by destructive distillation, the ammonia being recovered in the form of ammonium sulphate which has a value of \$70 per ton. The residue from the retorts is used for the manufacture of artificial stone or bricks.

At Oldham the grease is recovered from the sludge by distillation with steam. The dry residue from this process is sold for a small price as a fertilizer. It is thought to have little value for this purpose because a large part of the nitrogen is driven off in the distillation.

In Dublin a part of the sewage sludge "is mixed in large tanks with a small proportion of spent brewery yeast and fermentation is started by the aid of hot water pipes. The organic matter separates out and is dried and sold as fertilizer in powder form under the name of 'Fertilite,' \$12 per ton being obtained, and it is understood that there is a large demand for it."

**Sewage sludge disposal.** I. BARTLEY (*Municipal Engin.*, 42 (1912), No. 4, pp. 227-229).—This article covers much the same ground as that noted above.

**The private sewage disposal plant.** J. VAN V. MANNING (*Sci. Amer.*, 106 (1912), No. 15, pp. 332, 342, 343, figs. 6).—Simple systems adapted to the detached villa and farm or country house are described. The principal requirements of these disposal plants are "(1) preliminary treatment of sewage to liquefy solids and suspended impurities, and hold back grease, scum, and sludge; (2) purification of effluent by natural or artificial filtration; (3) an acre or more of land; and (4) slope sufficient for sewage to flow by gravity."

## SOILS—FERTILIZERS.

**Soils of the eastern United States and their use, XXIX-XXXV, J. A. BONSTEEL** (*U. S. Dept. Agr., Bur. Soils Circs.* 54, pp. 8; 55, pp. 10; 56, pp. 8; 57, pp. 10; 58, pp. 11; 59, pp. 10; 60, pp. 13).—These circulars discuss the following soil types with respect to geographical distribution, characteristics, surface features and drainage, use, improvement, and crop adaptations.

Circular 54 deals with the Crowley silt loam of which a total of 477,120 acres in 3 areas in central Arkansas and southwestern Louisiana has been surveyed and mapped by the Bureau of Soils.

Rice under irrigation constitutes the great dominant crop on this soil type, and it is stated that since 1885 the acreage has grown from practically nothing to hundreds of thousands of acres.

Circular 55 deals with the Chester loam of which a total of 600,680 acres in 8 areas in southeastern Pennsylvania, central Maryland, and north central Virginia has been surveyed and mapped.

The surface topography of the Chester loam is described as rolling to somewhat hilly and natural drainage is, therefore, well established. Some sections are considerably eroded and should be terraced and maintained in sod during a considerable portion of the crop rotation.

"The Chester loam is an excellent general-purpose farming soil; the principal crops grown are corn, wheat, oats, rye, potatoes, and hay."

Circular 56 deals with the Penn loam, of which a total of 320,266 acres in New Jersey, Pennsylvania, Maryland, and Virginia has been surveyed and

mapped. The soil is stated to be fairly well drained, but the more level portions of the type would be benefited by tile underdrainage.

Circular 57 discusses the Carrington silt loam of which a total of 739,584 acres in 7 areas in 5 States has been surveyed and mapped. This type is found upon the uplands of northern Indiana, southern Wisconsin and Minnesota, and in the eastern portion of both North and South Dakota. The drainage of the soil is adequate, as a rule, but in minor depressed areas tile drainage is considered necessary. The soil is well suited to the production of grains and grass, dairying and stock raising being the principal industry.

Circular 58 gives an account of the Carrington clay loam of which a total of 612,864 acres in 6 areas in 4 States has been surveyed and mapped. This type is found in southern Wisconsin, north and central Iowa, southern Minnesota, and eastern North Dakota. The drainage is good over the greater portion of the region, only small depressions requiring tile drains. "In the more southern and eastern areas corn, oats, and hay are the chief staple crops. Cabbages are raised as a special crop. Farther north spring wheat, barley, rye, and flax are grown, while in the most western areas of its occurrence durum wheat is coming to be an important and profitable crop."

Circular 59 discusses the Marion silt loam of which a total of 694,040 acres in 4 areas in Missouri and Illinois has been surveyed and mapped. This is a prairie soil adapted to small grain farming, winter wheat constituting the most important crop with oats and hay occupying considerable acreage. Drainage is stated to be imperfect in this type of soil which is also low in organic matter and needs lime.

Circular 60 deals with the Volusia loam of which a total of 554,082 acres in 7 areas in northern Pennsylvania, southern and central New York, and north-eastern Ohio has been surveyed and mapped. It is described as a general farming and dairying soil with an altitude ranging from 600 to 1,500 ft., a rolling to hilly surface fairly well drained except in depressed and level areas, and adapted to the production of grass for hay and pasture. Oats constitute the chief crop and barley and winter wheat are grown to a limited extent. In the lower areas corn is grown for grain and at the high altitudes flint varieties may be grown for silage. Buckwheat is an important catch crop.

**Soils of the Shenandoah River terrace: A revision of certain soils in the Albemarle area, Virginia.** H. H. BENNETT (*U. S. Dept. Agr., Bur. Soils Circ. 53, pp. 16, figs. 4*).—In revising some of the soils of the Albemarle area, Virginia, particularly the Edgemont stony loam, the author proposes to classify those soils of the lower, smoother division of the original Edgemont stony loam as the Waynesboro and the Holston series; and those of the mountainous belt of the region, as the Dekalb series. The principal soil types under each series are described.

**Soils in the San Luis Valley, Colo.,** M. H. LAPHAM (*U. S. Dept. Agr., Bur. Soils Circ. 52, pp. 26, fig. 1*).—The results of a reconnoissance survey of the region, including its climatic conditions, soils, and agriculture, are reported.

The region occupies a valley in south central Colorado about 80 miles long with a maximum width of 45 miles. The valley is flat and treeless. The soils of the foot slopes and alluvial fans are of porous, sandy, and gravelly character underlain by leachy, gravelly subsoils. The alluvial soils of the stream bottoms are usually sandy loams, loams, or clay loams underlain by gravelly subsoils. The soils of the marginal slopes are gravelly sand, sandy loam, or loam, and are derived mainly from volcanic rocks. They are leachy and not retentive of moisture. The northern and central parts of the valley contain small areas of the gravelly foot slope soils. The central and eastern parts of the valley

contain large areas of wind-drifted sands, broken by low flats without drainage and occupied in places by alkali lakes. Although only a relatively small proportion of the valley is now under cultivation, most of the soils are easily cultivated and well adapted to grains, grasses, legumes, and certain vegetables. Some of the lower lying slopes and depressions suffer from seepage water and alkali.

**The agricultural possibilities of the Canal Zone. Part I, Reconnaissance soil survey.** H. H. BENNETT (*U. S. Dept. Agr. Rpt. 95, pp. 5-38, pls. 10, fig. 1, map 1*).—This report which is accompanied by a paper on *The Outlook for Agriculture in the Canal Zone* (see p. 91) discusses the region with respect to physical features and area, climatic and agricultural conditions, forests, soils, and irrigation.

The soil material ranges from the fine beach sand through alluvial and coluvial clay loams of stream bottoms and lower slopes to the more predominant plastic, heavy residual clays of the hills. The residual clay types cover about 80 per cent of the available agricultural land and are formed through the decomposition in place of volcanic, igneous, and sedimentary rocks. The range in organic matter content of the residual types in samples analyzed was from 1.75 to 8.30 per cent, with few below 3 per cent. The clay loams of the bottoms and lower slopes contain sufficient organic matter and coarse grains to give a good tilth. The sandy lands which occur exclusively as narrow coast fringes consist principally of the coarser and more resistant particles of rock fragments, of stream sediments, and shore-line degradation products.

Characteristic of the soils are the small surface accumulation of vegetable mold and the strong resistance offered to erosion. The "rapid disappearance of plant remains is due in a large measure to the fact that the high humidity of the rainy seasons, followed by the winds of the warm dry season, favors rapid disintegration and oxidation of plant remains." The resistance to erosion is due to the universally low content of sand and high content of clay, coupled with the fact that the soils are never loosened by freezing. The lands are further assisted in holding place against wash by the dense vegetation and the almost total absence of cultivation.

**Records of drainage in India.** J. W. LEATHER (*Mem. Dept. Agr. India, Chem. Ser., 2 (1912), No. 2, pp. VIII+63-140, figs. 11; abs. in Chem. Abs., 6 (1912), No. 11, p. 1487*).—Studies of evaporation and of the amount, nitrate content, and movement of drainage water from fallow and from cropped soils at Cawnpore, 1903-1910, and at Pusa, 1906-1910, are reported. See also a previous note (*E. S. R., 23, p. 420*).

The evaporation was nearly independent of the season, whereas the drainage varied with the rainfall. A good crop reduced evaporation to two-thirds or one-half of that from fallow land. The amount of ammonia from both bare fallow and cropped land was as small as has been found at Rothamsted. The amount of nitrate in years of good rainfall was much greater than at Rothamsted. "The amount of nitrate in drainage water from cropped land is very much less than from fallow land, and there is some evidence that higher plants interfere with nitrification. Nitrification has been found at Pusa to be active only during wet weather and then only for a short time. The evidence of the Indian records goes to show that the water descending during wet weather passes very uniformly through the soil and not chiefly by means of 'larger channels' as has been commonly supposed."

**Lysimeter investigations, 1911.** E. KRÜGER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 4 (1912), No. 2, pp. 129-133*).—This is a continuation of previous work (*E. S. R., 25, p. 21*), and reports studies on the influence of

ground-water levels maintained at heights of 15.76, 31.52, and 47.28 in., and of soil aeration on the yield of oats. It is stated that the season was very dry.

The high water levels increased the yield of straw substantially as compared with the lower levels. A ground-water level of 31.52 in. below the surface was most advantageous and the amount of water required by this method for the production of a pound of dry matter was 618 lbs. as compared with 550 lbs. by sprinkling. Aerating the soil decreased the yield of crops in most cases, which was thought to be due to the sandy soils used and to the dry season.

**The flow of subsoil water, H. E. HURST** (*Cairo Sci. Jour.*, 6 (1912), No. 65, pp. 27-32).—In this paper an attempt is made to give part of the theory of the flow of a liquid through a porous medium, and to obtain the general equation of flow as simply as possible without applying the theory to the solution of any problems. The phenomena dealt with are those occurring in the saturated portions of the soil.

**Conservation of the soil, A. GRÉGOIRE** (*Rev. Écon. Internat.*, 8 (1911), IV, No. 2, pp. 368-383; 9 (1912), I, No. 2, pp. 391-408; II, No. 2, pp. 417-432).—This is a discussion by the director of the agricultural experiment station of Gembloux, Belgium, of the chemical, physical, and economic factors of soil conservation.

**The adsorption phenomena of cultivated soils, J. H. ABERSON** (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch.* [Wageningen], 5 (1911), No. 1, pp. 1-43, figs. 4; *Ztschr. Chem. u. Indus. Kolloide*, 10 (1912), No. 1, pp. 13-22; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 5, p. 243).—From the results of experiments with clay soils treated with varying amounts and concentrations of solutions of ammonium chlorid alone and with additions of calcium, potassium, and sodium chlorids and sodium nitrate, the author concludes that during the process of adsorption an equilibrium was established in the exchange of ions of the soil and of the added solution. It is held that this exchange of ions was not the result of a purely chemical reaction in the sense maintained by Guldberg and Waage. The addition of ions which reacted with those in the solution reduced the adsorption. Soil adsorption followed the same law as adsorption by charcoal, wool, silk, etc. Adsorption in the soil is held to be a function of the surface of the colloidal substances.

It would seem probable that the aluminum silicates in the soil are the compounds which take up the calcium, magnesium, potassium, and sodium ions, thus forming the adsorption compounds. There was a certain relation, although no exact proportionality, between adsorption and hygroscopicity (as determined by the Mitscherlich method) of the soil. Increasing the temperature lowered the adsorption of the soil just as in the case of other colloidal substances.

**The biological absorption of soils, J. STOKLASA** (*Chem. Ztg.*, 35 (1911), No. 154, pp. 1425-1427; *abs. in Chem. Zentbl.*, 1912, I, No. 12, p. 939).—Studies of the absorption of phosphate, potassium, ammonium, and nitrate ions from solutions of ammonium and potassium sulphates, ammonium and potassium chlorids, monocalcium phosphate, and potassium and calcium nitrates by sterilized and unsterilized soils, and soils inoculated with a culture of *Bacillus mycoides*, are reported. The process of absorption continued from 23 to 30 days, the solutions being allowed to percolate through the soil during this time.

The absorption of the phosphoric acid was from 3.8 to 14.5 per cent greater for the unsterilized than for the sterilized soils. This difference is attributed to the bacterial activity and is called the biological absorption. The biological absorption of all the ions was substantially smaller for acid or unsaturated and less fertile soils than for the alkaline or saturated and fertile soils. The

biological absorption increased with the alkaline character, porosity, presence of easily decomposed carbon compounds, and sufficient nitrogen in assimilable form. The absorption of ammonium and nitrate ions was dependent upon the presence of the phosphate and potassium ions. The absorption of the ammonium ion was from 3.12 to 8.01 per cent greater than that of the nitrate ion.

The general conclusion drawn is that in soil investigations, particularly as regards the question of productivity, account must be taken of the biological absorption as well as the physical and chemical absorption. It was found, for example, that rye plants made a much stronger growth in inoculated than in uninoculated, sterilized soils, thus indicating that the bacterial activity influenced the plant food of the soil and rendered it more readily assimilable by the plants. The productive soils showed a high biological absorption not only for the ammonium ion but for the phosphate and potassium ions as well.

**Biochemical relations of the phosphate ion in the soil,** J. STOKLASA (*Biochemischer Kreislauf des Phosphat-Ions im Boden*, Jena, 1911, pp. 159, pls. 12).—This is a reprint in book form of matter which has in large part already been noted from another source (E. S. R., 25, p. 624).

**The loss of ammonia from soils and experiments on the nitrogen balance in pot experiments,** P. EHRENBURG (*Fühling's Landw. Ztg.*, 61 (1912), No. 2, pp. 41-53).—This is a review of the work of O. Lemmermann (E. S. R., 26, p. 320), whose conclusions agree with those of the author as to the small losses of ammonia from the use of ammonium sulphate, and of A. Koch (E. S. R., 26, p. 319), who reports large losses of ammonia from the use of ammonium sulphate under certain conditions. The author maintains<sup>2</sup> that Koch used much larger amounts of ammonium sulphate and of lime than are ordinarily applied in practice and that, therefore, his results have little or no practical significance.

The author also refers to the work of Kraus (E. S. R., 26, p. 516) as indicating that the wind may be an important factor in influencing the rate of evaporation of ammonia from the soil.

**The loss of ammonia from manured soils,** P. EHRENBURG (*Fühling's Landw. Ztg.*, 60 (1911), Nos. 13, pp. 441-452; 14, pp. 479-500).—This is a critical review of the work of P. Liechti and E. Ritter (E. S. R., 25, p. 22), in which it is maintained that the amount of manure used by these investigators in their experiments was in excess of that which is ordinarily applied in rational systems of cropping and that, therefore, the results of the work as bearing on the loss of ammonia have no practical value.

**The loss of ammonia from soils,** P. LIECHTI and E. RITTER (*Fühling's Landw. Ztg.*, 61 (1912), No. 3, pp. 83-109).—This is a reply to the above, pointing out in a general way the fallacy of applying the results of experiments with manure to those obtained with ammonium sulphate. It is held that manure contains its ammonia in the form of carbonate, which is much more susceptible to loss of ammonia than ammonium sulphate, and that there is danger of considerable loss of ammonia when manure is applied as is ordinarily done in practice.

**Green manuring in Mysore,** L. C. COLEMAN, B. N. IYENGAR, and N. SAMPATIENGAR (*Dept. Agr. Mysore, Gen. Ser. Bul. 1, 1912, pp. IV+22, pls. 8, figs. 3*).—This bulletin gives the results of a 2-year study of green manuring as practiced in Mysore, particularly on paddy soils. It is shown that sunn hemp, cowpeas, different varieties of gram, and avare are used to a considerable extent as green manuring, but that the practice is very variable and not so extensive as it should be. Suggestions regarding the improvement of methods are made.

**The smells of manure works of Paris,** O. BOUDOUARD (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 4, pp. 238-240; *abs. in Jour. Soc. Chem. Indus.*, 31

(1912), No. 4, p. 196).—An investigation of the conditions affecting the odors of manure works showed that stocks of mineral phosphates gave off little or no odor, but that dissolved bone and phosphatic guano evolved evil-smelling odors which were increased by elevation of temperature, stirring, and variations in pressure and electrical conditions of the air. Odors from dry fertilizers lessen with time, but from moist fertilizers intensify as they gradually dry.

**Fertilizer resources of the United States**, F. K. CAMERON, R. B. MOORE, ET AL. (*U. S. Senate, 62. Cong., 2. Sess., Doc. 190, 1912, pp. 290, pls. 19, figs. 3, maps 19*).—This document, transmitted to the Senate by the President of the United States, is "a preliminary report on the fertilizer resources of the United States, describing investigations which have been carried out by experts of the Bureau of Soils, following a special authorization by the last regular session of Congress," with appendixes containing technical reports on the natural phosphates of Tennessee, Kentucky, and Arkansas, with a list of references to the bibliography of phosphates; memoranda on the manufacture of acid phosphate in the Southern States and on the manufacture of sulphuric acid and ammonium sulphate in this country; data regarding alkali crusts containing 0.5 per cent or more of potash; a list of patents for the extraction of potash salts; memoranda regarding saline claims, potash deposits, etc., and jurisdiction over kelp groves; and papers dealing with the botany, chemistry, industrial uses, and food value of the kelps of the coast of the United States and Alaska, with a bibliography of the literature of marine algae and their uses. The report explains the purpose and scope of the work undertaken by the Bureau of Soils and summarizes the more important results of this work to date.

It is stated that \$120,000,000 worth of fertilizers are now annually used in this country, but that "a much increased production and wider use of commercial fertilizers must accompany or closely follow the economic changes and readjustments now taking place in the United States."

It is believed that the United States has within its borders supplies of raw materials for fertilizers which "will be ample for a long but indefinite period. . . . This country is fortunate in having within its confines enormous deposits of natural phosphates, including the well-known fields of South Carolina, Florida, Tennessee, Arkansas, and Kentucky, lesser deposits in many other States, and the greatest deposit of the world in Montana, Wyoming, Utah, and Idaho."

Deposits of nitrates "have been found in this country, but none of commercial importance have yet been exploited. Ammonium salts, a product of the coke ovens and gas furnaces, slaughterhouse products, cotton-seed meal, and in lesser quantities, other nitrogenous organic materials, are utilized in the manufacture of fertilizers. The so-called atmospheric products, calcium cyanamid and basic calcium nitrate, are finding an increased use." The search for nitrate deposits in the United States is being actively prosecuted and other sources of nitrogen, especially ammonium sulphate from by-products of coke ovens, are being developed.

"Up to the present there have been no sources of potash in this country commercially developed." The search for mineral deposits of potash, which has been actively carried on, has given results which seem to warrant the continuation of such investigations (see abstract below), but the report holds that the most promising source of potash yet discovered in the United States is the kelp groves along the Pacific coast. These kelps "are essentially different in certain respects from the Atlantic kelps and apparently from those of Japan. They yield a much higher percentage of potash (five or six times as much as the Atlantic kelps), but have a much lower percentage of iodine."

It is estimated that "the Pacific kelps can easily be made to yield upward of 1,000,000 tons of potassium chlorid annually, worth at least \$35,000,000, and that the cost of production can largely, if not entirely, be covered by the value of the iodine and other minor products. The value of the present annual importations of potash salts from Germany is, in round numbers, \$12,500,000."

**Potash salts: Summary for 1911.** W. C. PHALEN (*U. S. Geol. Survey, Advance Chapter from Mineral Resources of the United States, Calendar Year 1911, pp. 31*).—This is an advance chapter from Mineral Resources of the United States, 1911, and reports the progress in work by the U. S. Geological Survey, the Bureau of Soils of this Department, and private persons in the search for a domestic supply of potash, which has included investigations of "(1) saline residues, (2) natural and artificial bitterns, (3) alunite and similar minerals, (4) the igneous rocks containing as a lower safe limit at least 6 per cent of potash ( $K_2O$ ), (5) the greensand marls of Kentucky, New Jersey, Tennessee, and probably other States, (6) organic sources, including wood ashes, beet-sugar molasses and residues, wool scourings, and seaweed."

The work of the Geological Survey in 1911 included "(1) deep drilling for saline residues, (2) the collection and examination of natural and artificial brines and bitterns, (3) the examinations of deposits of alunite and other minerals containing potassium, (4) the examination of certain occurrences of igneous rocks known to contain large quantities of potash." At the time this report was made the deep drilling operations had not revealed potash deposits of commercial importance; one Ohio bittern had shown a considerable percentage of potash (3.9 per cent); a considerable deposit of rather pure alunite (hydrous potassium and aluminum sulphate) had been discovered near Marysville, Utah (*E. S. R.*, 26, p. 526); and the extensive leucite deposits of Sweetwater County, Wyo. (*E. S. R.*, 26, p. 623), had been examined and their potash capacity estimated at 197,349,617 short tons of potash. The examinations of samples of other igneous rocks, particularly those rich in potash feldspar and of the potash-yielding capacity of New Jersey, Kentucky, and Tennessee marls had revealed little new information of special commercial importance. Accounts are given of the fruitless search for potash salines in the Otero Basin, New Mexico (see below), of methods of recovering potash from alunite and other igneous rocks and marls, and of simple field and laboratory tests for potash.

Data are given regarding the consumption of potash salts in the United States, amounting to 672,639,581 lbs. valued at \$11,826,106 in 1911, and the production of potash from wood ashes in the United States (1,866,570 lbs. valued at \$88,940 in 1910), and reference is made to the industries in which potash salts are used.

The work of the Bureau of Soils of this Department on kelp as a source of potash (see abstract above) is summarized, attention being called to the recent establishment at Cardiff, on the coast of southern California, of a plant for the manufacture of potash from kelp.

An investigation of the Otero Basin, New Mexico, for potash salts, E. E. FREE (*U. S. Dept. Agr., Bur. Soils Circ. 61, pp. 7*).—An investigation which led to entirely negative results is briefly reported in this circular.

**Potash from the Pacific kelps** (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 2, pp. 76, 77).—This is a brief discussion based upon the work of the Bureau of Soils of this Department on the possibilities of potash production from Pacific coast kelps.

**Leucite as a potash fertilizer**, Z. BONOMI (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata*, 3 (1909-10), pp. 17-25).—Comparative tests of leucite

and potassium sulphate as fertilizers for medic and *Lotus corniculatus* are reported. The leucite showed considerable fertilizing value, but much less than potassium sulphate.

**On the economic use of potassic fertilizers**, Z. BONOMI (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata*, 3 (1909-10), pp. 39-53).—This is a fourth paper on this subject (*E. S. R.*, 20, p. 925), and reports tests of potassic fertilizers on clover and medic, the general conclusion being that the use of potassium sulphate on these crops was economical.

**Comparative tests of calcium and sodium nitrates as fertilizers**, Z. BONOMI (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata*, 3 (1909-10), pp. 27-32).—The results of the series of experiments reported in this article were variable, sometimes favoring one nitrate and sometimes the other, but indicating on the whole about an equal efficiency for the two.

**Chilean production of nitrate**, A. A. WINSLOW (*Daily Cons. and Trade Rpts. [U. S.]*, 14 (1911), No. 203, p. 959; 15 (1912), No. 79, p. 39).—It is stated that the production of nitrate in Chile in 1911 was the highest ever recorded. It amounted to 54,297,531 Spanish quintals (of 101.4 lbs. each) during the nitrate year ended June 30, 1911, and 51,784,271 quintals during the calendar year 1911. The production during the calendar year 1910 amounted to 53,596,000 quintals. The business was prosperous notwithstanding the low prices which prevailed during the first 6 months of the year, and which fell as low as \$1.66 per quintal on board steamer on the coast in March. The price, however, gradually advanced to \$1.94 per quintal in October.

New works, which it is estimated will increase the output 18,000,000 quintals per annum, were in progress during the year, and the Chilean congress authorized the further sale of nitrate lands.

"The consumption of nitrate during 1911 increased 108,000 tons. The United Kingdom consumed 10 per cent more than in 1910, the United States 10 per cent, Holland 7 per cent, Belgium 7 per cent, France 4 per cent, and Italy 12 per cent, while Germany consumed about 4 per cent less."

**Lime for Alabama soils**, J. F. DUGGAR and M. J. FUNCHESS (*Alabama Col. Sta. Bul.* 161, pp. 301-324).—This bulletin discusses the forms, sources, and methods of application of lime, its action on different kinds of soils and crops, and its need in Alabama soils, and summarizes the results of experiments with lime in different parts of the State. It is stated that there are abundant sources of supply of lime in Alabama; also that there are large areas of acid soils in Alabama, although the exact extent of such soils has not been determined, and that "on most acid soils, as well as on some other soils, the use of lime generally increases the yield of most crops. . . ."

"In the lime tests made in various parts of Alabama the average increases in yield attributable to the use of lime were as follows: Cotton 23 per cent, corn 11, cowpeas (seed and hay) 14, peanuts 24, velvet bean hay 35, soy beans (seed and hay) 49, German millet hay 11, sorghum hay 47, chufas 0, and sweet potatoes (loss) 17 per cent."

The litmus paper test for determining whether a soil is acid is described.

**Liming the soil**, J. B. ABBOTT (*Indiana Sta. Circ.* 33, pp. 16, figs. 4).—This is a popular discussion of this subject adapted to Indiana conditions.

**The uses of peat for fuel and other purposes**, C. A. DAVIS (*U. S. Dept. Int., Bur. Mines Bul.* 16, 1911, pp. 214, pl. 1, fig. 1).—This bulletin gives the results of an investigation primarily into the possibility of the economic use of peat as a fuel in the United States. Incidentally attention was also given to other uses of peat, namely, for the production of ammonium compounds and other chemical products and for fertilizers and other agricultural purposes.

It is stated that "peat land may be cultivated with profit if the right crops are chosen and the peat is sufficiently drained, decomposed, and fertilized. Many of the peat swamps in the northern part of the country are, however, of a type that will scarcely repay cultivation, since the peat is very poorly decomposed and would be a long time in reaching a state in which it could be safely used for most crops.

"On the other hand, even poorly decomposed peat may be very profitably used in many ways on farms to increase the fertility of the land, and to add to its productiveness indirectly, by conserving and preserving other more salable articles, or by saving valuable waste matter which could not be kept except by its use."

### AGRICULTURAL BOTANY.

**British fungi and lichens.** G. MASSEE (*London*, [1911], pp. X+551, pls. 42, figs. 19).—This book contains chapters on the classification of fungi, how to study them, their collection and preservation, ecology, edible and poisonous fungi, diseases caused by fungi, etc. In part 2, which constitutes the greater portion of the work, the systematic arrangement of fungi is treated at length, many of the species being illustrated by colored plates. A rather brief chapter on lichens concludes the text. The primary object of the work is said to be to enable the reader to determine the names of the indigenous mushrooms, toadstools, etc.

**Enzym studies of lower fungi.** A. W. DOX (*Plant World*, 15 (1912), No. 2, pp. 40-43).—During the progress of a study of fungi, including the more common saprophytic molds, the author has demonstrated the presence of 14 enzymes and he shows their ability to hydrolyze various substances and the products of the hydrolysis. From the data obtained in the study of fungus enzymes, he believes that there is much to argue against the present conceptions of the specificity of enzymes.

**Oxidizing enzymes in certain fungi pathogenic for plants.** H. S. REED and H. S. STAHL (*Abstr. in Science*, n. ser., 35 (1912), No. 897, p. 396).—The authors call attention to the difference in the oxidizing ability of plant extracts as altered by parasitic fungi. The extracts of apples invaded by *Sphaeropsis malorum* are said to show no oxidizing powers, while those attacked by *Glomerella rufomaculans* show a somewhat increased oxidizing ability. When grown in pure cultures on synthetic media *Glomerella* was found to develop oxidizing enzymes in certain media but not in others.

**The root nodules of *Myrica gale*.** W. B. BOTTOMLEY (*Ann. Bot.* [London], 26 (1912), No. 101, pp. 111-117, pls. 2).—The author reports a study of the origin and structure of the root nodules occurring on *M. gale*, only 4 groups of nonleguminous plants, alders, *Elæagnus*, *Podocarpus*, and cycads, having previously been recognized as possessing root nodules which are concerned with the assimilation of atmospheric nitrogen.

The peculiar nodule formations on the roots of *M. gale* have been frequently described, and the author has determined that from their structure they are outgrowths of lateral rootlets. They are caused by the presence of bacteria which are evidently similar to *Pseudomonas radicola*, and experiments in flasks inoculated with cultures showed an increase of 2.05 mg. of nitrogen per 100 cc. of culture. Experiments with *Myrica* plants grown in sterilized soil showed that they did not flourish unless they possessed root tubercles. Plants devoid of tubercles, after inoculation with a culture, developed root nodules and grew well.

The morphology of the root tubercles of *Alnus* and *Elæagnus*, and the polymorphism of the organism causing their formation, ETHEL R. SPBATT

(*Ann. Bot.* [London], 26 (1912), No. 101, pp. 119-128, pls. 2).—A study of the root tubercles of *Alnus* and *Elaeagnus* proves that they are modified lateral roots and are produced by infection of the root with a race of the nitrogen-fixing organism *Pseudomonas radiculicola*. This bacillus enters the root and propagates itself in the cortex of the nodule as a rod-shaped organism. *P. radiculicola* is believed to be a polymorphic organism exhibiting the bacillus and coccus forms. In *Elaeagnus* the bacteria are found mainly in the region immediately behind the growing point, while in *Alnus* the bacteroidal tissue traverses the entire length of the nodule. The coccus form is believed to be correlated with a scarcity of available carbohydrates and a change of environment, and it is more resistant to the influence of external agencies than the rod-shaped form. The organism was proved to be capable of fixing free atmospheric nitrogen when isolated from the tubercles.

**Nitrogen nutrition of *Aspergillus niger***, W. BRENNER (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 8, pp. 479-483; *abs. in Jour. Chem. Soc.* [London], 101 (1912), No. 591, II, p. 77).—Experiments with *A. niger* in which a large number of forms of nitrogen were used are reported, and it is shown that ammonium lactate, tartrate, succinate, and oxalate, and asparagin were the most suitable compounds, followed by carbamid and the mineral salts of ammonia. In the case of pyridin nitrate, only the nitric nitrogen seemed to be assimilated. Free ammonia, sodium nitrite, ammonium valerate, and potassium cyanid were toxic.

**The rôle of nitrogen in plant metabolism**, J. M. PETRIE (*Proc. Linn. Soc. N. S. Wales*, 36 (1911), pt. 1, pp. 97-149, *dgm.* 1).—In continuation of previous studies (E. S. R., 22, p. 437), a further account is given of the rôle of nitrogen in plant metabolism. Studies are reported on the distribution of nitrogen in the seeds of *Acacia pycnantha*, the nitrogen in ripening seeds of *Vicia* spp., and the occurrence of potassium nitrate in plants. This latter substance, though one of the principal forms in which plants receive their nitrogen from the soil, was found by the author stored as a reserve in considerable quantity in a shrub, *Solandra grandiflora*.

The author believes that in green plants nitrates contribute to the formation of protein, without light, provided that carbohydrates be supplied, and that this change always begins by a reduction of the nitrates through nitrites to ammonia. Instead of the sudden transformation of the nitrate, he thinks it more probable that the enzymic reduction of nitrate to ammonia is the natural one. It is believed that the stages are the formation of ammonia, the production of hydrocyanic acid from formaldehyde through formic acid, ammonium formate, and formamid, and in the same way the passage of aldehydes in general through their acid amids to nitriles. From the interaction of ammonia, hydrocyanic acid or nitriles, and the various aldehydes, can be produced the amino-acids, and hence the synthesis of proteids.

**Can humus be directly assimilated by the higher plants?** M. MOLLARD (*Compt. Rend. Acad. Sci.* [Paris], 154 (1912), No. 5, pp. 291-294).—Experiments are reported with radishes grown in tubes containing sterilized and unsterilized soil to which was added ordinary soil humus. The analyses of the dry matter obtained showed in some instances an increase and in others a decrease of carbon, which must have come from the humus in the culture. The difference, however, was so slight that the author concludes that if humic material is directly assimilable by green plants it is in a very insignificant amount.

**The influence of phytin on seedlings**, A. R. ROSE (*Abs. in Science*, n. ser., 35 (1912), No. 897, p. 393).—Phytin, which is found almost universally in seeds and is considered to play a significant rôle in their germination, has been investigated to determine if possible what the influence of the phosphorus con-

found may be upon the earliest growth of the plants. Lupine seedlings were germinated and afterwards allowed to grow in nutrient solutions, some of which contained a phytin compound.

The results seemed to indicate that the several phytates behave in the same manner as the corresponding orthophosphates. There was no suggestion of any specific influence of the phytic anion upon the seedlings. The phytin solutions in which the seedlings had been grown showed no increase in inorganic phosphorus or inosit, and there was, therefore, no evidence that the phytase of the seed acted upon the phytin in the surrounding liquid.

**The action of sulphur on plants,** E. BOULLANGER (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 6, pp. 369, 370).—In the course of some experiments on catalytic fertilizers, a series was carried on with carrots, beans, celery, lettuce, chicory, potatoes, onions, etc., in which 70 gm. of sulphur was added to 30 kg. of soil. The influence of the sulphur was apparent in every case and in some very conspicuous, exerting a favorable action on the growth of the plants and notably increasing the yield. Another series of experiments with sulphur used in connection with sterilized and nonsterilized soil showed that the action of the sulphur was quite pronounced with ordinary soil but had a very feeble effect with the soil that had been sterilized.

From this it is believed that sulphur does not act directly upon the bacterial flora of the soil nor assist materially in the development of certain organisms. Its exact action is to be investigated further.

**The effect of ether and carbon bisulphid on plants,** A. KOEN (*Centbl. Bakt. [etc.]*, 2. Abt., 31 (1911), No. 5-19, pp. 175-185; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 599, II, p. 112).—Experiments are reported on the growth of buckwheat and mustard in soils that had been treated with ether and carbon bisulphid in varying quantities. Two crops were grown in each pot, one immediately following the application of the ether and the other seeded after the first crop had been removed.

A greater total yield as well as a higher amount of combined nitrogen was always found in the plants immediately following the application of the ether. The second crop, whether it was mustard or buckwheat, was less in yield and combined nitrogen than the first, and in some cases less than the check pots.

The investigations seem to show that the activity of the ether and carbon bisulphid is exerted in stimulating the development of the plant and that the increased yields were due to this fact and not to the influence of the substances on the nitrifying and denitrifying organisms.

Experiments with yeasts showed that fermentation was favored by a small amount of ether. Carbon bisulphid gave negative results, while it appeared to delay acid formation in the fermenting mash.

**The effect of guanidin on plants under different conditions,** O. SCHREINER and J. J. SKINNER (*Abs. in Science, n. ser.*, 35 (1912), No. 897, p. 391).—The effect of 50 parts per million of guanidin, which has been generally considered harmful to plants, was tested on wheat seedlings in solution cultures and in soils.

Its toxicity did not show until the fifth or sixth day, when spots appeared on the leaves, but soon the plant was completely affected, falling over by the end of the second week. The effect of nitrates in the cultures was especially striking in that the harmful effect first showed itself in the cultures highest in nitrates and spread gradually to those lower in nitrates, frequently not appearing at all in those cultures which contained phosphate and potash but no nitrate. This seems to be an instance of a harmful nitrogenous constituent, accentuated by nitrates.

The influence of chemicals on the germinating capacity of dodders, G. D'IPPOLITO (*Staz. Sperc. Agr. Ital.*, 44 (1911), No. 3-4, pp. 301-308; *abs. in Riv. Patol. Veg.*, 5 (1911), No. 6, p. 86; *Chem. Zcutbl.*, 1911, II, No. 6, p. 370; *Jour. Chem. Soc. [London]*, 102 (1912), No. 591, II, p. 82).—Experiments are reported on the use of chemicals for destroying *Cuscuta arvensis* and *C. trifolia*.

Ammonium nitrate, sodium carbonate, calcium cyanamid, and formalin were found to kill dodder seeds, while potassium nitrate and carbonate did not entirely inhibit their germinating capacity. Sodium and calcium nitrates were less efficient, and magnesium sulphate is said to have had hardly any action.

The author recommends, for destroying dodder seeds in the soil, treatment with either a 2 per cent solution of ammonium nitrate or a 1 per cent solution of formalin.

The sterilization of seed in relation to the micro-organisms contained by them, G. ROSSI (*Rend. Soc. Chim. Ital.*, 2. ser., 2 (1910), pp. 276-280).—The difficulty of completely sterilizing seed without destroying their germinative ability is well known. The author gives the results of experiments to secure the sterilization of a number of kinds of seed. Lots of 25 seeds of each kind were placed for 3 hours in a 3 per cent solution of hydrogen peroxid, after which single seeds were transferred to tubes and placed in an incubator, where they were kept for 25 days.

No species of seed remained completely sterile, molds and bacteria making their appearance in different lots in from 5 to 15 days. Fifteen tubes containing seed of maize, 10 of dried peas, 23 of fresh peas, and 8 of lentils became infected. Only 1 each of chick-peas and Dolichos and 2 of wheat were contaminated at the end of the experiment.

Influence of continued electric currents on the growth of plants, F. KÖVESSY (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 5, pp. 289-291).—The author reports experiments with wheat, supplemented by observations on rye, oats, barley, vetch, beans, various grasses, and a number of species of trees, as well as mosses, algae, and various fungi.

The results obtained confirmed the conclusions of previous investigators that a continued electric current exerts a retarding effect on growth and is decidedly injurious to the germination of seed and the development of plants. The factors which determine the effect of electricity on plants are summarized, and it is shown that the intensity and potential of the current, the conductivity of the medium, and the various physical and biological factors which influence the life of the plant, as well as the chemical changes which take place, all exert an important rôle in plant growth as influenced by electricity.

The liberation of heat in respiration, G. J. PEIRCE (*Bot. Gaz.*, 53 (1912), No. 2, pp. 89-112, *dgms.* 8).—In a previous note (*E. S. R.*, 20, p. 734), the author gives a description of the value of Dewar flasks as respiration calorimeters for class use. Subsequent studies have confirmed their usefulness in physiological experiments. In the present paper an account is given of their use in germination studies with peas, and also of a study on the heat liberated by a mouse placed in a flask.

In the series of experiments with peas, seeds of different ages were germinated in the flasks. It was found that the amount of heat liberated by germinating peas decreased with their age, and apparently that the amount of heat liberated during germination may be used as an index of the age or freshness of seed.

Discussing the significance of heat liberation in respiration, the author calls attention to the fact that there is a much greater release of energy in the form of heat than can possibly be used by the organism, and states that it is evident

that if liberation of heat is the essential result of respiration, respiration must be an excessively wasteful process. He does not believe that respiration is primarily carried on for the purpose of furnishing the living organism with energy in the form of heat, as is often taught. He states that "the liberation of heat may be used, like carbon dioxide, by the physiologist as a gauge of the activity of respiration, but like carbon dioxide, it must be regarded by him as an end product, a waste, and not the essential product. The essential product of respiration may be energy, but if so, it is that energy which is immediately convertible, and is converted into work by the organism. On the other hand, respiration may be essentially a process of purification, in which useless or injurious substances are converted into forms which can be eliminated."

In conclusion he says: "In this study of heat liberation, therefore, I believe I have been occupied with an unessential, although inevitable, feature of the process of respiration. The essential part of the process of respiration is much more likely to be found to be chemical and not physical."

**Incipient drying in plants.** B. E. LIVINGSTON (*Obs. in Science, n. ser.*, 35 (1912), No. 897, pp. 394, 395).—Attention is called to the fact that when water loss from the exposed membranes of leaves occurs at a higher rate than that at which water of imbibition enters these membranes the surfaces begin to dry. This phenomenon, which the author terms incipient drying, is said to occur in leaves which are subjected to relatively high transpiration. The drying acts as an automatic check upon transpiration.

**The water balance of desert plants.** D. T. MACDOUGAL (*Ann. Bot. [London]*, 26 (1912), No. 101, pp. 71-93, pls. 5).—In continuation of previous accounts (E. S. R., 26, p. 530), the author describes experiments with *Lechinocactus*, *Carnegiea*, *Opuntia*, *Ibervillea*, *Dioscorea*, *Brodiea*, and other plants and discusses the physiological value of the water balances of the plants studied.

He states that the actual physiological value of water balances varies widely, as shown by his experiments with the different plants. All showed a high rate of water loss immediately upon removal from the soil, after which the curve of transpiration fell. In some instances the plants remained alive for a number of years.

**The relation of soil acidity to plant societies.** A. W. SAMPSON (*Obs. in Science, n. ser.*, 35 (1912), No. 898, p. 436).—This is an abstract of a paper presented before the Botanical Society of Washington in February, 1912, which reports a study on the relation of soil acidity to plant cover based on range vegetation observations made in the Wallowa Mountains of northeastern Oregon.

It is stated that "the Leguminosæ are commonly extremely sensitive to acid soils, while many ericaceous species are rather closely confined to acid soils. For example, *Trifolium repens* fails in soils requiring for neutralization the relatively small amount, locally, of 5,000 lbs. of lime per acre-foot, while no species of *Vaccinium* is known that can be grown successfully in neutral or alkaline soils. Again, some genera (e. g., *Populus* and *Rosa*) are apparently indifferent as regards soil preferences. The preeminent forage plant of the Wallowa Mountains, *Festuca viridula*, varies very widely in adaptability to acidity. The soils on which it grows luxuriantly vary in lime requirements from 5,000 to 41,000 lbs. per acre-foot. The 4 species of *Poa* and the 2 species of *Agropyron* occurring locally reach their best development on calcareous and neutral soils."

**The weeds of arable land in relation to the soils on which they grow, II.** WINIFRED E. BRENCHLEY (*Ann. Bot. [London]*, 26 (1912), No. 101, pp. 95-109).—A study of 106 species of weeds to determine whether definite associations exist

between species of weeds and the soils on which they grow is reported (E. S. R., 25, p. 28).

In each district investigated there appears to be a definite association, which may be either local or general. If local the presence of a weed is considered symptomatic of a certain soil, but not exclusively so. If the association is a general one it is believed to indicate that this species is characteristic of the same type of soil in all districts. There was little evidence found to show an association between weeds and certain crops.

**Toxic excreta of plants.** F. FLETCHER (*Jour. Agr. Sci.*, 4 (1912), No. 3, pp. 245-247, pl. 1).—In a previous publication (E. S. R., 20, p. 521), the author showed an apparent antagonism of sesame to sorghum, the sesame plants not maturing in the presence of the sorghum. The cause of this behavior was attributed to toxic substances secreted by the sorghum roots. Field experiments with maize and sesame have since been carried on in Egypt, and they appear to show the excretion of toxic material by the roots of maize plants.

**The injurious influence of tarred roads on neighboring vegetation,** L. MANGIN (*Jour. Agr. Prat.*, n. ser., 22 (1911), No. 35, pp. 271-274, figs. 3).—On account of conflicting opinions regarding the effect of tarring roads on neighboring vegetation, a commission has been appointed to consider the injury, if any, to the trees and shrubs in the parks of Paris. A summary of the findings of the commission is given, of which the essential conclusions have been noted elsewhere (E. S. R., 25, p. 128).

**Herbage studies. I.—Lotus corniculatus, a cyanophoric plant,** H. E. and E. F. ARMSTRONG and E. HORTON (*Proc. Roy. Soc. [London], Ser. B*, 84 (1912), No. B 574, pp. 471-484).—Tests have been made of bird's-foot clover (*L. corniculatus*) by means of sodium picrate papers for the presence of hydrogen cyanid. In 1910 the authors concluded that this plant occasionally contained a cyanophoric glucosid and its corresponding enzym. The experiments were repeated in 1911 with specimens of this plant from many regions, and the glucosid and enzym were rarely absent. The experience has led the authors to correlate the appearance in *L. corniculatus* of the cyanophoric glucosid and the attendant enzym with conditions favoring maturity rather than luxuriance of growth.

*L. corniculatus major*, or *L. uliginosus*, as it is sometimes called, has always proved free from hydrogen cyanid, as have the species *L. tetragonolobus*, *L. siliquosus*, *L. bertholctti*, and *L. jacobaus*.

The authors request botanists to test *L. corniculatus* by the above method and report their results to them.

**Investigations on heredity.** W. JOHANNSEN (*Fortschr. Naturw. Forsch.*, 3 (1911), pp. 71-136, figs. 27).—This is a discussion of heredity as it applies to descent and segregation among plants and animals. A considerable bibliography of the subject is given.

**On the cause of dimorphism in *Oenothera nanella*,** H. H. ZEIJLSTRA (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 13 (1911), pt. 2, pp. 680-685, pl. 1).—The author for a number of years has been investigating the dimorphism of *O. nanella*, one of the forms which is said to have arisen by mutation from *O. lamarckiana*. A large number of plants of this species have been studied, and the author has come to the conclusion that *O. nanella* is quite constant in its appearance when grown from seed.

In 1905 among these specimens dwarf plants were frequently observed, and a study of them showed in the stems blackened masses, which were found to be made up of Micrococcus. This bacterium is believed to be the agent causing the malformation.

**Contribution to the study of buds.** PERRIAZ (*Bul. Soc. Vaud. Sci. Nat.*, 5. ser., 46 (1910), No. 170, pp. 445-458, figs. 7).—Anatomical and biological

studies were made of buds of a number of trees, and the author reports that 2 distinct bud forms should be recognized. In the first the bud scales are attached uniformly at the base of the bud, and fall when the young leaves have begun their development. This is true in the case of the ash, horse chestnut, maple, and apple, and the scales function only as protective organs. In the second series the bud scales are arranged in spiral order, and as examples of this the author cites ampelopsis, horn bean, beech, and hazel. In these during the course of their development the scales become modified, develop some chlorophyll, and have the function of young leaves. They fall later, only after the development of the branch and expansion of the true leaves.

**Graft hybrids**, R. P. GREGORY (*Gard. Chron.*, 3. ser., 50 (1911), Nos. 1288, pp. 161-163, figs. 3; 1289, pp. 185, 186, fig. 1).—A description is given of the graft hybrids *Solanum tuberosum*, *Cytisus adami*, and *Cratago-mespilus asniensis*, and their origin as shown by the investigations of Winkler, Heuer, Baur, and others is discussed.

**International catalogue of scientific literature. M—Botany** (*Internat. Cat. Sci. Lit.*, 9 (1911), pp. VIII+859).—This gives a bibliography of botanical literature, most of which appeared in the years 1907-1909, 6314 references being included. The American literature is much more adequately represented in the present volume than in the previous ones.

## FIELD CROPS.

**Classification of field crop varieties**, F. MERKEL (*Mitt. Deut. Landw. Gesell.*, 26 (1911), No. 13, pp. 162-166).—The author classifies German varieties of field crops in accordance with their adaptation to special uses. Potatoes, for instance, are divided into groups of varieties high in yield of tubers, high in starch content, and high in total starch yield. The article deals with wheat, barley, mangels, sugar beets, potatoes, grasses, clover, and various legumes.

[**Wisconsin farm crops experiments**], H. L. RUSSELL (*Wisconsin Sta. Bul.*, 218, pp. 15-20, figs. 3).—At the Ashland substation, the pedigree strains of Green peas yielded at the rate of 50 bu. per acre and of Kharkov winter wheat over 45 bu. per acre.

Western alfalfa seed grown in the latitude of Madison, Wis., proved entirely satisfactory and work done indicates that the vitality of the seed is more important than the variety sown. In soy bean work the number of pods per plant ranged from 30 to over 400.

Tests of commercial bacterial cultures showed "that while in some instances satisfactory inoculation has been secured, they are frequently unreliable, and fail to produce nodules upon the roots of the respective legumes, while inoculation with infected soil has been uniformly successful."

The growing of hemp aided in checking the growth of Canada thistles and quack grass. A  $3\frac{1}{2}$ -acre field infested with quack grass and Canada thistles was heavily manured, plowed in July, harrowed weekly, and the loose roots removed with a hay rake. A hemp crop sown at the rate of 1 bu. per acre the following spring yielded over 2,100 lbs. of fiber per acre, valued at \$118, and "resulted in complete destruction of thistles, and nearly complete annihilation of quack grass."

A solution of 125 lbs. of common salt in 50 gal. of water proved as effective as a 20 per cent iron sulphate solution for the eradication of mustard. The salt is more easily obtained than, and costs about half as much as, the iron sulphate.

**Results of cooperative experiments in agriculture**, C. A. ZAVITZ and W. J. SQUIRELL (*Ann. Rpt. Ontario Agr. and Expt. Union*, 32 (1910), pp. 14-37).—

These pages report the results of cooperative tests conducted in Ontario during 1910. The work included variety tests of oats, six-rowed, two-rowed, and hull-less barley, spring and winter wheat, buckwheat, field peas, soy beans, emmer, spelt, mangels, sugar beets, Swedish and fall turnips, carrots, sweet, fodder, and silage corn, millet, sorghum, grass peas, vetches, rape, kale, field cabbage, clover, alfalfa, grasses, field beans, early, medium-ripening, and late potatoes, and winter rye. Fertilizer tests with oats, winter wheat, fodder corn, mangels, Swedish turnips, and potatoes involved the use of nitrate of soda, muriate of potash, superphosphate, and a complete fertilizer, while cow manure also was used with winter wheat, Swedish turnips, and potatoes. These tests covered periods varying from 4 to 8 years. A table states the average results reported from 5 tests of nitrate of soda, muriate of potash, superphosphate, lime, and cow manure singly or in various mixtures in 1910 for barley.

[Fertilizer tests on swamp soils], R. HARCOURT (*Ann. Rpt. Ontario Agr. and Expt. Union*, 32 (1910), pp. 44, 45).—Applications of (1) acid phosphate and sulphate of ammonia, and (2) acid phosphate, sulphate of ammonia, and sulphate of potash were followed by yields of 96 and 176 bu. of potatoes, respectively, as compared with 96 bu. per acre on the check plot. The tests were conducted on swamp soils.

[Adaptation experiments], J. H. HAMPTON (*Rhodesia Agr. Jour.*, 8 (1911), No. 6, pp. 853-862; 9 (1911), No. 1, pp. 16-23, pls. 4).—These articles state briefly the results of tests conducted to determine whether certain crops could be profitably grown under southern Rhodesian conditions. The crops tested were alfalfa, Egyptian clover, velvet beans, cowpeas, lupines, peanuts, sweet potatoes, wheat, oats, millet, flax, mangels, sugar beets, swedes, kohlrabi, carrots, rape, beans, peas, *Paspalum dilatatum*, *Phalaris bulbosa*, and sheep burnet (*Sanguisorba minor*).

[Fertilizer and variety tests], J. JOHNSTON (*Dept. Agr. Brit. East Africa Ann. Rpt. 1910-11*, pp. 133-160).—These pages report the results obtained in fertilizer, variety, and other tests with alfalfa, rape, corn, beans, wheat, mangels, sugar beets, peas, potatoes, barley, *Paspalum dilatatum*, and flax.

Supplementary pasture crops, M. L. FISHER and F. G. KING (*Indiana Sta. Circ.* 35, pp. 16, fig. 1).—A general discussion of forage crops for the hog is followed by special suggestions on growing for this purpose rape, cowpeas, soy beans, Canada peas and oats, rye, oats, vetches, crimson clover, sorghum, artichokes, mangels, sugar beets, carrots, and pumpkins.

Tables suggest crops suitable for planting during each month from April to October, information for use in planting each of a number of crops, and crop successions for "hogging down" in Indiana.

[Chemical and physical observations on Eritrea cereals], O. MANETTI (*Agr. Colon. [Italy]*, 5 (1911), No. 3, pp. 100-113).—The crops dealt with are *Sorghum vulgare*, *Elyusine coracana*, *Eragrostis abyssinica*, and *Pennisetum spicatum*. Tables state date gathered in observations of the color, purity, germination, chemical composition, and specific gravity of the seed.

Trials with grains and legumes for feeding purposes, 1899-1908, F. HANSEN (*Tidsskr. Landbr. Plantearb.* 18 (1911), No. 4, pp. 485-542).—The results of trials at 6 Danish experiment stations indicated that for feeding purposes it is generally better to sow a mixture of 100 lbs. oats, 50 lbs. two-rowed barley, 75 lbs. Glänö peas, and 25 lbs. vetches than to sow only a single crop.

Barley alone or mixtures in which barley predominated gave the highest yields on the best soils, while oats or mixtures consisting largely of oats yielded best on the poorer soils.

**Eighteen years' culture trials with root crops, L. HELWEG** (*Tidsskr. Landbr. Plantæavl.*, 18 (1911), No. 5, pp. 675-678, figs. 2).—This report covers cultural tests with mangels, swedes, turnips, and carrots conducted during the period 1906-1910 on 68 different farms (151 experimental fields) in northern and western Jutland, and supplements earlier reports for the period 1893-1905.

The average results for the entire 18 years show that the yield of dry matter was somewhat larger for swedes than for mangels (83.4 and 80.8 cwt. per tøndeland, or 61.2 and 59.3 cwt. per acre, respectively), about 25 per cent less for carrots than for mangels, and about 20 per cent less for turnips than for swedes. The special conditions under which the various crops are to be preferred for different sections of the country are discussed, and a rotation intended to guard against insects and fungus diseases is suggested.

**The agave, F. MICHOTTE** (*Agr. Prat. Pays Chauds.*, 12 (1912), Nos. 106, pp. 1-15; 107, pp. 150-162, figs. 2).—A botanical study of the plant and description of its more important characteristics is followed by directions for its propagation and culture, and a statement of its climatic requirements and the results of a chemical analysis.

**Soils of the prairie regions of Alabama and Mississippi and their use for alfalfa** (*U. S. Dept. Agr. Rpt.*, 96, pp. 48, pls. 7, figs. 4).—This report consists of 2 parts.

I. *Houston clay and associated soils*, H. H. BENNETT (pp. 5-31).—A previous discussion of the Houston clay has been previously noted (*U. S. R.*, 26, p. 517). The author discusses Houston chalk, Houston loam, and Trinity clay as soils associated with and closely related to the Houston clay. As soils associated with but not closely related to the Houston and Trinity soils he discusses Oktibeha, Susquehanna, Orangeburg, stream bottom soils associated with Trinity clay, Ocklocknee, and Bibb soils.

II. *Alfalfa on the Houston clay: Its culture and management*, M. A. CROSBY (pp. 32-48).—In view of the fact that alfalfa growing is increasing in importance on the Houston clay soils of Alabama and Mississippi, and that climatic and soil conditions here differ from those of other alfalfa sections, the author gives directions for alfalfa production in this region. Special consideration is given to alfalfa on Johnson grass land and on Bermuda sod.

**How to grow alfalfa, A. T. WIANCKO and M. L. FISHER** (*Indiana Sta. Circ.*, 36, pp. 16, figs. 6).—This is in part a reprint of a circular dealing with the production and use of alfalfa in Indiana already noted (*U. S. R.*, 25, p. 440).

On June 2, 1908, a cutting of 285 lbs. of hay was secured from a plat sown on the thirtieth of the previous July, as compared with 315 lbs. from a plat sown August 10, and 135 lbs. and 11 lbs., respectively, from sowings made August 24 and September 12. Of 269 successful alfalfa growers, 196 regarded a nurse crop as unnecessary while 73 favored it.

**Genetic studies with the beet, B. KAJANUS** (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 6 (1912), No. 3, pp. 137-179, pls. 9, figs. 2).—The author states briefly the results of each of a considerable number of hybridizations in which he used beets of different varieties. The notes given deal particularly with the size, shape, and color of the roots and leaves.

**A new plant fiber, A. ZIMMERMANN** (*Pflanzer*, 7 (1911), No. 4, p. 231).—The author reports tests of the fine silky hairs from the seeds of a plant determined as *Chlorocodon whitei*. It was found in German East Africa and further experiments in its production have been taken up there.

**Local fertilizer experiments with cotton in South Alabama in 1911, J. F. DUGGAR, J. T. WILLIAMSON, L. L. GLOVER, and E. HODSON** (*Alabama Col. Sta. Bul.*, 160, pp. 241-296).—The results of local fertilizer experiments or soil tests

conducted "to ascertain the best fertilizers or combination of fertilizers for cotton growing on each of the principal soils of the southern half of Alabama" are reported. The applications used and the yields and financial returns obtained on a considerable number of farms are summarized, but no general conclusions are drawn.

**Local fertilizer experiments with cotton in North Alabama in 1911, J. F. DUGGAR, J. T. WILLIAMSON, L. L. GLOVER, and E. HODSON** (*Alabama Col. Sta. Bul. 152, pp. 56*).—This bulletin is similar to the above, except that it presents studies made in the northern half of Alabama. No general conclusions are drawn.

**Cotton culture in North Carolina** (*Bul. N. C. Dept. Agr., 33 (1912), No. 2, pp. 36, fig. 1*).—Discussions of the botanical relations of the cotton plant and of the soil, cultural, and other problems connected with its production in North Carolina are followed by tables stating the results of variety tests conducted in 10 different localities in the State. In most instances the yields reported are for 1911, but some of the tables cover the period 1901–1911.

**Heading off boll weevil panic, W. E. HINDS** (*Alabama Col. Sta. Bul. 159, pp. 225–238, fig. 1*).—A continuation of a previous discussion (E. S. R., 23, p. 55).

A map shows the Alabama weevil line of 1911, including 5 counties and portions of 7 others, and the quarantined area. A review of the boll weevil situation is followed by suggestions to bankers, cotton factors, merchants, and others relative to loans or advances as affected by the boll weevil. It is believed that in most cases loans may continue to be made with safety to the limit of from 50 to 75 per cent of what might be advanced if the boll weevil were not present, provided the grower will so reduce his acreage as to ensure the best of care and will provide for diversification of crops.

Tables showing the acreage devoted to cotton in several States and the average yield secured during certain years since 1894 present data which may be summed up in the following table:

*Effect of weevil infestation on cotton acreage and yield per acre.*

Year.	Acreage.				Bales per acre.				Percentage of weevil infestation.			
	Ala.	Miss.	La.	Tex.	Ala.	Miss.	La.	Tex.	Ala.	Miss.	La.	Tex.
1894....	2,664,861	2,826,272	1,313,296	6,854,621	0.337	0.435	0.579	0.458	0	0	0	0.25
1898....	3,065,176	2,900,298	1,281,691	6,991,904	.391	.429	.560	.481	0	0	0	11.00
1902....	3,501,614	3,183,989	1,617,586	7,649,331	.279	.455	.548	.326	0	0	0	34.50
1905....	3,658,000	3,408,000	1,739,000	8,894,000	.345	.446	.563	.457	0	0	23.00	71.00
1909....	3,471,000	3,291,000	930,000	9,660,000	.307	.337	.290	.264	0	0.90	100.00	80.00
1910....	3,560,000	3,317,000	975,000	10,060,000	.343	.377	.263	.305	0	14.00	100.00	82.00

**British cotton growing, J. H. REED** (*Jour. Manchester Geogr. Soc., 26 (1910), No. 4, pp. 179–197, pls. 6*).—The author predicts that unless cotton supplies are obtained from fields other than those of America, the Lancashire industry will completely perish. The British demand for raw cotton is slightly less to-day than it was 25 years ago, but that of other countries has gradually increased. Between 1892 and 1910 the British demand decreased 4 per cent, while that of continental Europe increased 70 per cent and that of the United States 90 per cent. In view of these conditions the author discusses the possibility of increasing the cotton production of India, Egypt, and other British territory.

Seed selection series. **I. Broach cotton**, T. F. MAIN (*Dept. Agr. Bombay Bul.* 46, 1911, pp. 3, pls. 5).—A description of the ideal broach cotton plant and directions for field selection are accompanied by photographs illustrating the characters to be sought or avoided in obtaining plants of the proper habits and fiber of sufficient length for high-ginning qualities.

**Sakellaridis cotton** (*Bul. Imp. Inst. [So. Kensington]*, 9 (1911), No. 3, p. 288).—This article reports the discovery of a new type of cotton in Egypt by Sakellaridis. It matured earlier than Mitafifi, but flourishes in the same districts and in districts which are not suitable for Yannovitch. The fiber is soft, silky, cream-colored with reddish tinge, of good strength, and from 1.4 to 1.7 in. in length. Experts valued it at 14½ cts. per pound as compared with "fine" Yannovitch at 13½ cts. per pound.

[Cotton tests at the botanical garden of Palermo], A. BOZZI (*Bol. Min. Agr., Indus. e Com. [Rome]*, Ser. C, 10 (1911), No. 5, pp. 1-5).—The author reports the results of variety tests of tree, Bulgarian, Mitafifi, and American cottons, and hybrids of Trabut and of the colonial or botanical garden of Palermo.

Tests indicated that irrigation aided the development of the plant, but delayed the maturity of the bolls. The drought resistance of the plants leads the author to predict a great extension of cotton culture.

**Fertilizing ingredients in Danish hay crops**, R. K. KRISTENSEN (*Tidsskr. Landbr. Plantearb.* 18 (1911), No. 4, pp. 543-569).—Chemical analyses are reported showing the nitrogen, phosphoric acid, and potash contents of timothy, rye grass, white, red, and alsike clovers, and of other grasses and legumes grown at the Danish Experiment Station at Askov during the period 1905-1909. The material was obtained from the experiments with hay crops grown under different systems of fertilization on clay, sand, and marsh soils.

**A note on onion couch**, L. M. UNDERWOOD (*Jour. Agr. Sci.*, 4 (1912), No. 3, pp. 270-272, figs. 4).—The author notes the difference of opinion as to whether the bulbous form of *Arrhenatherum arvenaceum* is entitled to specific rank and states the results of pot tests conducted on various soils and under different moisture conditions. From these tests, he concludes "that the habit of forming bulbs is hereditary and does not depend on the conditions of the habitat. Other than the bulbs, no differences in habit were noted between the 2 plants."

**Potatoes at Wisley, 1911** (*Jour. Roy. Hort. Soc. [London]*, 37 (1912), No. 3, pp. 569-575).—Brief descriptions are given of each of more than 70 varieties of potatoes tested.

**Six years' potato variety tests at Sindlingen**, R. ADLUNG (*Württemb. Wehnl. Landw.*, 1912, No. 10, pp. 164-166).—A table states the yields of tubers and starch obtained during each year of the period 1906-1911 in a test of 34 varieties.

**A new potato** (*Bul. Union Cent. Synd. Agr. France*, 1910, Nov. 1, p. 341; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intcl. and Plant Diseases*, 1910, No. 2, p. 248).—This article discusses a potato variety said to be resistant to attacks of *Phytophthora infestans*. It is stated that the plants reach a height of 2.43 meters.

**The thornless prickly pears**, D. GRIFFITHS (*U. S. Dept. Agr., Farmers' Bul.* 483, pp. 20, figs. 4).—A statement of the geographical distribution of thornless prickly pears and their moisture, temperature, and soil requirements accompanies directions for propagating, planting, cultivating, harvesting the crop, and transporting the cuttings. Other topics discussed are varieties, the botanical status of thornless prickly pears, and the stability of the spineless character.

[Advice on prickly pear destruction] (*Queensland Bd. Advice Prickly Pear Destruct., Interim Rpt. 1, 1911, pp. 19*).—This report, presented to the houses of Parliament of Queensland, deals with the destruction of the prickly pear by such mechanical means as stacking, burning, rolling, and plowing in, by poisoning with or without subsequent burning, by diseases or insect enemies, and by utilization as fodder or in other ways.

San hemp (*Crotolaria juncea*), P. C. PÁTIL (*Dept. Agr. Bombay Bul. 47, 1911, pp. 9*).—A botanical description of the plant and statement of its uses is followed by suggestions for growing the crop and retting it.

Grain-sorghum production in the San Antonio region of Texas, C. R. BALL and S. H. HASTINGS (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 237, pp. 30, figs. 4*).—The San Antonio region of Texas is adapted to the production of grain sorghums, but they have failed to set seed. This condition, known as "blast," has been attributed to the removal of pollen by heavy rains during the blooming period. The authors report experiments during which it was discovered that this trouble was caused by the sorghum midge (*Contarinia (Diplosis) sorghicola*). They also describe attempts to find resistant varieties and state the results of experiments indicating the possibility of avoiding the work of midges by early planting.

Life history studies supplemented by those of Dean (*E. S. R., 23, p. 364*) are reported. "More than 1,000 [midges] have been hatched from a single head of sorghum. Observations and experiments in 1908 and 1909 failed to find midge-resistant sorghums in any group." In 1910, early planting experiments indicated that the crop could be brought to the blooming stage before the midge was present in sufficient numbers to be very injurious. In 1911, the average yield of all varieties planted March 4 was 23.1 bu., and of the best early variety 32 bu. per acre. Corn on similar land in the same season yielded an average of 10 bu. per acre. Planting as late as April 1 proved unprofitable because of midge injury and drought, but when planted March 15 early varieties yielded very well, while later varieties yielded more poorly. Milo and Dwarf milo maize, Manchu kowliang, and White durra are the earliest varieties. Sudan durra and Dwarf Kafir corn are also promising.

The authors recommend the destruction of Johnson grass and sorghum plants in fence corners and waste places, in order that fewer midges may survive the winter and that the succeeding crops may be more likely to flower without infestation. In view of the results of experiments they also recommend fall plowing for conserving moisture and state that for prompt and uniform germination a thoroughly prepared seed bed is essential. Kowliangs should be planted 5 to 6 in. apart in rows 3½ feet apart, milo maize and durras from 6 to 8 in. apart, and Kafir corn from 8 to 10 in. apart. The date of planting should be as near March 1 as possible, as the risk from late spring frosts is more than compensated by avoiding the midge and drought injury.

Observations on the early flowering of the sugar beet, O. MUNERATI (*Malpighia, 24 (1911), No. 2, pp. 173-187*).—Sowings of 6 varieties of sugar beets at intervals from November 14 to June 15 indicated a decisive effect of the time of sowing on the tendency to premature flowering, but no relation between the number of plants flowering the first year and the yield secured.

Of the beets sown November 15 and December 23, 55 and 65 per cent, respectively, flowered during the first season, but after that time the percentage decreased steadily until of those sown March 14 only about 1 per cent flowered, and of those sown April 26 or later none flowered the first season. The composition of the large, medium, and small beets, as shown by analyses, is reported in tabular form.

**Sweet clover.** J. M. WESTGATE and H. N. VINALL (*U. S. Dept. Agr., Farmers' Bul.* 485, pp. 39, figs. 16).—This discusses the various species of sweet clover, outlines its status in various sections of the United States, and gives directions for growing, cutting, and curing the crop. Its uses for hay, in rotation as a soiling crop, and as a soil improver are summarized, and directions are given for seed production and for the eradication of the crop when it becomes a weed. White sweet clover (*Melilotus alba*) is the species principally discussed, but the yellow annual and biennial species (*M. indica*) and (*M. officinalis*) are briefly treated. An outline map of the United States shows that localities in 22 States are successfully utilizing sweet clover as a forage crop.

The ordinary slow germination due to hard seed may be overcome by soaking the seed in concentrated commercial sulphuric acid just before sowing and washing rapidly in an abundance of water with frequent changes. Tests of this method gave an increase in germination of from 40 to 45 per cent. Southern grown seed is about 60 per cent, northern grown 43 per cent, and imported seed about 12 per cent hard. The presence of this hard seed, which does not usually germinate the first season, may enable sweet clover to continue in a meadow a number of years without reseeding.

Its habits of growth do not make sweet clover troublesome under ordinary conditions. Its control is especially difficult only under irrigation conditions where old plants along ditch banks furnish seed which is scattered each year by the irrigation water.

**The culture of cigar leaf tobacco in Texas.** O. OLSON (*Texas Sta. Bul.* 147, pp. 3-42, figs. 11).—A summary of previous tobacco work in Texas carried on by this Department and general information on the production, harvesting, and curing of cigar-leaf tobacco in Texas are followed by statements of work on a tobacco demonstration plat and of the results of experimental work.

The cost of cigar-filler tobacco to the buyer or packer is reported as approximately 25 cts. per pound, including the items of 15 cts. for barn-cured tobacco, 3 cts. for loss in weight during fermentation, 1 ct. for fermentation, 3 cts. for assorting, sizing, and tying, 1 ct. for baling, and 2 cts. for rent, supervision, etc. The total cost per 1,000 cigars for Texas Cuban filler tobacco, and the necessary binders and wrappers is estimated at about \$15.25. The cost per acre of growing, stripping, and tying is estimated at \$78.

The author states in detail the methods used and results obtained in rotations in fertilizer tests with tobacco, from which he concludes that the average yields of 500 lbs. of Texas Cuban and 800 lbs. of Big Cuban can be increased to at least 1,000 and 1,300 lbs. per acre respectively. In addition to the low yield secured from the check and no-nitrogen plats, the leaves were generally "thin and papery, while the laboratory tests indicated less aroma and flavor and much less ability to stand a heavy fermentation than the tobacco from the highly fertilized plats." Potash alone did not prove conducive to a good yield, although a tobacco grown after its use ranked very high in aroma, flavor, and burn. Phosphoric acid caused a rapid and highly desirable growth, and the author recommends the use of 16 per cent acid phosphate. The methods used in the seed beds are briefly stated, and a table gives the grades awarded the tobacco grown on each of 12 fertilizer plats, in accordance with score card points.

Notes are given on the varieties and types grown on the variety and breeding plats.

**Cultural tests of Herzegovina tobacco in Italy.** ABBATE (*Bol. Tec. Coltiv. Tabacchi [Scafati]*, 10 (1911), No. 3, pp. 161-164).—These experiments were conducted in Comiso, Italy, on soils of different types.

Water content of soil and nitrogen fertilization in relation to the development of Göttingen bearded square-head winter wheat in different vegetation periods, K. MEYER (*Ueber den Einfluss verschieden hohen Wassergehalts des Bodens in den einzelnen Vegetationsstadien bei verschiedener N-Düngung auf die Entwicklung des Göttinger begrannten Squarchead-Winterweizens*. Inaug. Diss., Univ. Göttingen, 1908, pp. 90, pls. 3).—These tests were conducted in zinc pots 33 cm. high and 25 cm. in diameter. Each contained 20 kg. of soil to which had been added 1 gm. of potash in potassium carbonate and 1 gm. of phosphoric acid in monocalcium phosphate. To some 1.5 gm. of nitrogen in nitrate of soda was added, and to others only 0.5 gm. of nitrogen. The water content of the soil was maintained at 45 per cent of its absolute water-holding capacity during the first vegetation period, and at 70 per cent during the rest of the test. In other cases this order was reversed.

From the data presented the author draws the following conclusions: The water consumed is less in case of high nitrogen fertilization, and high water content of the soil markedly increases the total yield only in case much nitrogen is present. The ratio of grain to straw is reduced by the presence of a large amount of moisture if plant food is not present in sufficient quantity. Grain formation is favored by an increase in the amount of water present during the last vegetation period.

Tillering is influenced by nitrogen fertilization and the amount of water present. The weight of the roots is increased by nitrogen fertilization and by an increase in the amount of water present, but the same root mass will produce more grain and straw on a fertile soil than on a thin soil. The total length of haulm depends generally on the water content of the soil during shooting. Tillering is unfavorable to length of haulm only when the soil is deficient in plant food. Potash fertilization does not determine the relative length of internodes and haulms. The length of the upper internode is influenced by the water content of the soil, particularly at the time of shooting, while the length of the lower internodes depends on the water content during the first vegetation period. Abundant fertilization and soil moisture increase the strength of the straw and weight of head. Tillering reduces strength of straw and weight of head only when accompanied by lack of plant food. The water supply during the first vegetation period governs the length of head and the number of kernels per head. Barren spikelets result from unfavorable water and food conditions. Increased moisture at the time of shooting gave the lowest number of barren spikelets in the case of high nitrogen fertilization.

Nitrogen fertilization rather than the water content of the soil appeared to be of importance in determining the number of blossoms per spikelet; it also favored symmetry of head. The less nitrogen there is available the more the soil moisture influences symmetry of head. In case of change in the amount of water, only a high moisture content during the first period exerted an unfavorable influence on the symmetry of head.

Other things being equal, the length of beard increased with length of head. Insufficient moisture during the first vegetation produced long beards, but much moisture produced a weak development of beard. There appeared to be no constant relation between length of beard and weight of grain. The longest beards appeared higher on the head than did the heaviest kernels.

With low nitrogen fertilization the heaviest kernels appeared in the lower portion of the ear, while high nitrogen fertilization apparently resulted in a tendency for the heavy kernels to appear at the middle of the head. The 1,000-kernel weight varied with the soil moisture in case of the heavier application of nitrogen. Plant food was low if much moisture was applied at an

early stage to the pots with only 0.5 gm. of nitrogen. Excessively high nitrogen fertilization with continued droughts reduced the 1,000-kernel weight.

By grouping the haulms and heads with reference to fertilization and the amount of water supplied the author obtained quite regularly graded series of data on length, weight, fruitfulness of head, and 1,000-kernel weight. The regularity of this gradation was also maintained in case of the number of kernels per head when much water was supplied during the first vegetation period.

**Report of the Danish seed control station, 1910-11.** K. DORPH-PETERSEN (*Tidsskr. Landbr. Plantearb.*, 18 (1911), No. 5, pp. 679-718).—These pages summarize the results of purity and germination tests, made during the period 1901-1911, of 9,024 samples of seeds of 32 species of clovers, grasses, root crops, and small grains. The frequency of occurrence of various weed seeds is stated.

[**Tests of Bombay seeds**], I. G. D. MEHTA (*Dept. Agr. Bombay Bul.*, 49, 1911, pp. 27).—The results of analyses and germination tests of seeds commonly grown in the Ahmednagar district of Bombay are reported.

## HORTICULTURE.

**Report on the government horticultural gardens, Lucknow, for the year ended March 31, 1911.** H. J. DAVIES (*Rpt. Govt. Hort. Gardens Lucknow*, 1911, pp. 8).—A progress report discussing administrative affairs, conditions of the gardens, character of the season, acclimatization and other experiments, financial results, and miscellaneous work.

**Report of the fruit branch of the department of agriculture, Ontario, 1910.** P. W. HODGETTS ET AL. (*Rpt. Fruit Branch Dept. Agr. Ontario*, 1910, pp. 167, figs. 41).—This report contains a general survey of the work of the fruit growers' and bee-keepers' associations, the experimental fruit stations, nursery inspection, and orchard surveys, together with other cooperative and miscellaneous work of the year.

**Return of inspections of fruit and vegetables for year ended June 30, 1911.** E. G. E. SCRIVEN (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1910-11, p. 10).—A statistical review of the export and import fruit and vegetable trade of Queensland.

**Spraying to control the important insects and fungus diseases affecting the fruit and foliage of the apple.** W. M. SCOTT (*Thomson Chem. Co. Circ.* 4, 1912, pp. 26, pls. 4).—A practical treatise based largely upon the results secured from the work of this Department and the State experiment stations.

**Orchard spray calendar.** M. W. RICHARDS (*Indiana Sta. Circ.* 34, pp. 12, figs. 12).—This circular contains a complete spraying schedule for orchard fruits, with recommended formulas for preparing the materials and the approximate time of application for those which are most important and most generally used.

**Lime-sulphur wash.** L. CAESAR (*Ontario Dept. Agr. Bul.* 198, 1912, pp. 44, figs. 28).—This bulletin summarizes the results of the latest investigations and experiments in making lime-sulphur wash and the various uses to which it can be applied.

**Valencia melon industry.** R. FRAZER, JR. (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 106, pp. 474, 475).—An account is given of the winter melons grown in the Valencia district, with reference to varieties, methods of planting, and seed selection.

**Onions.** A. McMEANS (*Ontario Dept. Agr. Bul.* 199, 1912, pp. 24, figs. 14).—A reprint of a survey of the onion industry in Ontario, Michigan, Indiana, Illinois, and Ohio, previously noted (*E. S. R.*, 21, p. 236).

**The pear and how to grow it**, G. B. BRACKETT (*U. S. Dept. Agr., Farmers' Bul.* 482, pp. 31, figs. 30).—This is a popular treatise on pear culture based on practical experience.

The subject matter is discussed under the following general headings: Dwarf and standard trees, propagation, location of the orchard, fertilizers, planting the orchard, selection of trees, cultivation, cover crops, pruning and training, protection from rodents, diseases and insect enemies, thinning the fruit, gathering the fruit, sorting and grading, packages, the fruit room, and disposing of the crop. Abridged descriptions are given of select varieties of pears.

**The plums of New York**, U. P. HEDRICK ET AL. (*New York State Sta. Rpt.* 1910, pt. 2, pp. XII+616, pls. 100).—This is the third of a series of monographs on the fruits of New York (E. S. R., 20, p. 940). Although the work has a special significance for New York State, its contents are considered sufficiently general to be offered as a record of the present knowledge of cultivated plums and to be applicable to the whole country and more or less to the world.

In the first chapter the history and general characters of plums are discussed; a conspectus showing the relations of the species to each other is given; and each species is described and discussed in detail relative to its literature, botanical characteristics, and varietal groups. Chapter 2 discusses the present status of plum culture in America under the following headings: Climate, the pollination of plums, locations and soils, stocks and propagation, plum orchards and their care, harvesting and marketing, diseases, and insects. A table is given showing the averages of the blooming dates at the New York State Station of varieties of plums for the 8 years 1902 to 1909. Chapter 3 describes the leading varieties of plums. The technical descriptions are for the most part original and the aim has been to give a concise idea of all of the characters of each variety. Synonyms and important references are also given. Chapter 4 contains briefer descriptions of the minor varieties of plums.

The color plates of species and leading varieties are a valuable adjunct to the text. A bibliography is given containing all horticultural books in America dealing with the plum, together with the European books and all periodicals referred to in the volume.

**Report on orcharding and the wine industry**, II. BRÖNNLE (*Pflanzer*, 7 (1911), No. 12, pp. 722-742).—A report on the development of the fruit and wine industries in German East Africa, including information relative to cultural practices, principal insect pests and diseases, and their control.

**Grape culture**, E. R. FARRAR (*Agr. of Mass.*, 1910, pp. 151-155).—A short article on commercial grape culture with special reference to Massachusetts conditions.

**The family strawberry patch and the way to make it a success**, W. BOUTON (*Alpena, Mich.*, [1911], pp. 62).—A popular treatise on this subject.

**Roselle, its cultivation and uses**, P. J. WESTER (*Philippine Agr. Rev.* [English Ed.], 5 (1912), No. 3, pp. 123-132, pls. 2, fig. 1).—An account of the roselle (*Hibiscus sabdariffa*) relative to its history, botany, and geographical distribution; varieties; soil, planting, and cultivation; harvesting and yield; composition and uses; diseases; and insect pests.

The only disease that has been thus far noted on the roselle is the mildew (*Oidium* sp.), which was found in Florida to attack the plant in the cool, damp fall nights. This is easily controlled by dusting with dry sulphur when the plants are wet with dew.

**The Sour orange bud as a remedy for gummosis of citrus trees**, L. SAVASTANO (*R. Staz. Sper. Agrum. e Frutticol. Acireale, Bol.* 7, 1912, pp. 4, figs. 2).—A popular bulletin, in which the author calls attention to the value of Sour

orange stock for citrus trees which are apt to be attacked by gummosis, and also to the practice of inserting Sour orange buds beneath the wounds of trees already attacked by gummosis. These buds, which are allowed to grow for 2 or 3 years, appear to arrest the disease and the wound becomes callused over.

When the buds become too rank in growth they are removed and the operation is repeated by starting 1 or 2 new Sour orange buds below the wound. This method is of special value for renewing old lemon trees.

**English walnuts**, W. F. ALLEN (*Lawrenceville, N. J., 1912, pp. 29, pls. 4, figs. 3*).—This comprises a compilation of information relative to planting, cultivating, and harvesting English walnuts.

**Making a lawn**, L. J. DOOGAVE (*New York, 1912, pp. 51, pls. 8*).—A handbook on lawn making, the successive chapters of which discuss the small lawn, old, and new; the treatment of large areas; grass seed; sowing the seed; sodding; good loam and fertilizers; the lawn mower, roller, and hose; and weeds and other pests.

**Amateur gardencraft**, E. E. REXFORD (*Philadelphia and London, 1912, pp. 300, pls. 3½*).—A popular treatise on ornamental gardening.

Consideration is given to making and planting the lawn, shrubs, vines, the hardy border, the garden of annuals, the bulb garden, the rose, the dahlia, the gladiolus, lilies, plants for special purposes, arbors, summer houses, pergolas, and other garden features, together with a memorandum of operations for the year.

**Garden profits**, E. L. D. SEYMOUR (*Garden City, N. Y., 1911, pp. 2½5, figs. 57*).—A practical treatise on city and suburban gardening.

**One hundred and fifty small gardens**, C. HAMPEL (*150 kleine Gärten. Berlin, 1910, 4, col. ed., pp. IV+202, figs. 150*).—This work contains plans, descriptions, and planting suggestions for 150 small gardens, representing both formal and natural arrangements and combinations of the two.

**Let's make a flower garden**, HANNA R. VERBECK (*New York, 1912, pp. 208, pls. 31*).—A popular treatise on flower gardening, containing information relative to cultural details, garden arrangement, suitable plants, etc.

**Orchids**, J. O'BRIEN (*New York [1912], pp. IX+11½, pls. 8*).—A popular treatise on orchid culture, including information relative to diseases and insect pests, hybridizing, and raising seedling orchids, and an enumeration of the principal genera and species in cultivation.

**Carnations and pinks**, T. H. COOK, J. DOUGLAS, and J. F. McLEOD (*New York [1912], pp. IX+116, pls. 8, figs. 2*).—A popular treatise containing historical notes, cultural details, and information relative to different types and varieties of carnations and pinks.

The work concludes with a calendar of operations.

## FORESTRY.

**The elements of British forestry**, J. NISBET (*Edinburgh and London, 1911, pp. XII+3½5, figs. 92*).—A handbook for forest apprentices and forestry students.

The subject matter is presented under the general headings of silviculture, the management and protection of woodlands, and the utilization of woodland produce.

**Forestry for woodmen**, C. O. HANSON (*Oxford, Eng., 1914, pp. 222, pls. 12, figs. 15*).—A popular work on scientific forestry, based largely on the important literature on the subject, and prepared especially for practical foresters and woodmen.

The successive chapters discuss the life history of a tree; tree growth in relation to climate and soil; pure and mixed woods; nursery management; sowing and planting in the forest; tending of woods; methods of treatment; protection of woods against destructive animals, birds, and insects, weeds and fungi, and against frost, drought, storms, and fires; silvicultural notes on broad-leaved trees and conifers; fencing and draining; felling and measurement of timber; working plans; and the uses of British timber.

**Wood and forest.** W. NOYES (*Pcoria*, III., 1912, pp. 309, figs. 140).—A handbook of information relative to the sources, growth, properties, identification, and uses of the common American woods.

The successive chapters discuss the structure and properties of wood, the principal species of American woods, the distribution and composition of the North American forests, the forest organism, natural enemies of the forest, the exhaustion of the forest, and the use of the forest. Information for distinguishing different woods is appended, also a general bibliography on wood and forestry.

Sixty-six species of American woods are considered relative to their habitat, characteristics of the tree, appearance of wood, physical qualities, and common uses. Illustrations are given in each case of the leaf of the tree and of the radial, tangential, and cross sections of the wood. The woods are also listed in order of their weight, strength, elasticity, and hardness.

**On forest types.** A. K. CAJANDER (*Fennia; Bul. Soc. Geogr. Finlande*, 28 (1909), No. 2, pp. IV+175).—This comprises a detailed study of the forest flora in a number of German forest districts, conducted principally to determine to what extent a knowledge of plant groups is of value for scientific forestry investigations and for practical forestry. A similar study of the forms in the vicinity of Brixen is appended.

For the region studied the author found that the dominant forest forms fell into a comparatively small number of types, which were readily characterized by certain dominant plants of the ground flora. The forest types were widely distributed and the same type was found to occur at altitudes ranging from 5 meters to 600 meters. The author concludes that the occurrence of a forest type is not exclusively influenced by any one factor, such as the physical and chemical composition of the soil, exposure, altitude, etc., since the same type is found on various soils and exposures. The forest types appear to be much more the result of the total effect of locality factors than as formations which occur on similar biologic localities. The ground vegetation does not appear to be materially influenced by the dominant tree or trees. Each forest type appears to have a special growth energy. The accretion of the same timber species in different types is quite variable, but within the same type there are no great differences. Within one and the same forest type similar regeneration and silvical methods are applicable to the same timber species.

**Experiments on the periodicity of some tropical trees,** II. DINGLER (*Sitzber. K. Bayer. Akad. Wiss., Math. Phys. Kl.*, 1911, No. 1, pp. 127-143).—In order to throw some light on the cause of the normal leaf fall which occurs with many native species in Ceylon during the drought period in March, the author conducted pruning experiments with many of the species growing in the Peradenyia Botanic Garden and Experiment Station and elsewhere.

The results, as here tabulated and discussed, show that if the trees are pruned in the fall the resulting vigorous new leaf growth formed in December passes through the normal leaf-fall period without dropping off. From these results the conclusion is formed that the normal leaf fall of these tropical trees can not be attributed primarily to external conditions of the temperature, moisture, etc., and that measures taken to control the temperature and moisture

conditions will not prevent the normal leaf fall. The cause of the leaf fall, which appears to lie in part at least within the plant, has not been thus far determined.

On the periodicity of central European deciduous trees in the mountain climate of Ceylon, H. DINGLER (*Sitzber. K. Bayer. Akad. Wiss., Math. Phys. Kl., 1911, No. 2, pp. 217-217*).—In connection with the above investigation the growth performance of a number of deciduous forest and fruit trees, native to Central Europe and growing at Nuwara Eliya and Hakgala in the mountains of Ceylon, was observed.

From the data thus far secured the author is led to conclude that the temperate climate trees, when thus transferred to the tempered tropical mountain climate at the above named places, make 2 growth cycles in a year with little, if any, resting period between. The first cycle commences in spring and ends in fall, at which time the trees recommence their life activities almost immediately, the cycle ending by spring. The leaves from the summer growth are carried over into the late winter, when conditions seem favorable for their falling off without at the same time seriously retarding the development of the new growth.

This continuous growth performance, however, appeared to weaken the reproductive activities of both the forest and fruit trees observed. Many kinds of trees matured their fruit but the yield was much less than in their native land. Vegetative development was greater in a number of cases, as with oaks, pears, cherries, and to a certain degree peaches, and less in other cases, such as the red beech and birch, than in the natural habitat of these trees.

It is stated that no conclusion can be drawn as yet from the information at hand as to the cause of this variation.

The strength, elasticity, and other properties of New South Wales hardwood timbers, W. H. WARREN (*Sydney: Dept. Forestry, N. S. Wales, 1911, pp. 100, pls. 16, figs. 67*).—This report gives the results of the following tests commenced in 1907 and continued up to December, 1910: Compression tests of cubes to determine any variation in strength of wood growing at different heights above the ground; the strength and elasticity of large and small timber beams; the strength and elasticity of long and short columns subjected to compression; shearing and tensile strength of timber; the holding power of nails and spikes; the compressive strength across the fiber; hardness and torsion tests; resistance to wear in floors and street pavements; impact; and tests of beams. The tests were made on various eucalypts, as well as with the turpentine tree (*Syncarpia laurifolia*), brush box (*Tristania conferta*), and the colonial teak (*Flindersia australis*). The testing methods are fully described and the results are tabulated and further explained by numerous diagrams and illustrations.

A careful consideration of the results obtained from the tests of cubes taken from 5 sections of the tree shows that with the same moisture content present in each case, the timber cut from the highest section is slightly, but not materially, stronger than that cut from the other 4 sections. Each timber was found to have a characteristic strength moisture curve beyond a certain point in which additional moisture does not seriously reduce the strength. Diminution of moisture below this point, on the other hand, produces an important increase in strength, which is much greater in some timbers than in others. The results illustrate the importance of seasoning on the strength of timber and also indicate that certain timbers exposed to the weather may become considerably reduced in strength.

*Hevea brasiliensis*, G. VERNET (*Bul. Écon. Indo-Chine, n. ser., 14 (1911), Nos. 92, pp. 777-826; 93, pp. 917-944; 15 (1912), No. 94, pp. 40-98, figs. 7*).—

Part 1 of this study treats in detail of the preparation and industrial value of different grades of raw Para rubber. Part 2 deals with the culture and exploitation of Para rubber in the Malayan Peninsula, in Java, and in Ceylon.

On the anatomy of *Hevea brasiliensis* and *Manihot glaziovii* with reference to tapping, P. ARENS (*Meded. Proefstat. Malang, 1911, No. 1, pp. 3-11, figs. 5*).—A short descriptive account.

An irrigation method for tapping *Hevea*, T. WURTH (*Meded. Proefstat. Malang, 1911, No. 1, pp. 15-18, figs. 2*).—A method of providing a small but constant supply of water to the tapping incisions is described and illustrated.

[Tapping experiments] (*Ann. Rpt. Agr. Dept. South. Nigeria, 1910, pp. 9-14, 34-36, 39*).—Experimental tappings of Ceara and Para rubber trees made at different points in Southern Nigeria are reported.

On the coagulation of the latexes of some *Euphorbias*, A. ZIMMERMANN (*Pflanzenz. 7 (1911), No. 12, pp. 742-744*).—The latexes of a number of *Euphorbias* were successfully coagulated with a 1 or 2 per cent solution of tannin.

On heath burning for reforestation, E. WIBECK (*Meddel. Stat. Skogsforsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens), 1911, No. 8, pp. 7-94, figs. 35*).—During the period 1888 to 1893 a number of experimental areas were established in the heath districts of Sweden to determine the best silvicultural methods for these soils, a special study being made of the effect of burning over the lands previous to reforestation. The results secured on these areas are here reported in detail.

The species planted were pine, spruce, and birch. Regardless of soil and cultural methods the pine alone has made good growth. Burning over the land appears to increase the growth in some localities and to check it in others. Generally speaking, deep soils with a medium amount of moisture show the greatest improvement from burning over. Burning during dry periods is apt to cause injurious ground fires. Burning off the vegetation from dry, sandy soils, shallow soils, and wet soils is of doubtful value and may even prove harmful.

From 2 to 3 times as much seed was necessary to secure a stand on unburned land as on burned land.

A new sowing method in the mountains, HAUENSTEIN (*Forstw. Centbl., n. ser., 34 (1912), No. 4, pp. 207-217, figs. 3*).—A hand seed drill for sowing forest seed in rough mountainous lands is described and illustrated.

The Spranz seed sower, SCHUNZINGER (*Allg. Forst u. Jagd Ztg., 88 (1912), Apr., p. 143, fig. 1*).—A hand apparatus for broadcasting coniferous seeds is illustrated and described.

Progress report of forest administration in Baluchistan for 1910-11, MULRAJ and H. DOBES (*Rpt. Forest Admin. Baluchistan, 1910-11, pp. III+34*).—This is the customary report of the forest conservator relative to the constitution, management, exploitation, and administration of the state forests in Baluchistan, including a financial statement for the year 1910-11. The principal data are appended in tabular form. The report is reviewed by the revenue commissioner.

## DISEASES OF PLANTS.

Bacteria in relation to plant diseases, II, E. F. SMITH (*Carnegie Inst. Washington Pub. 27, vol. 2, 1911, pp. VIII+368, pls. 20, figs. 148*).—This is in continuation of the author's monograph on the diseases of plants due to bacteria, the first volume of which has been noted elsewhere (*E. S. R., 17, p. 263*). In the first volume the general subject of bacteria and methods of work was discussed, while in the second volume the history of the subject, general considerations, and vascular diseases are treated.

After a very full review of the early literature relating to bacterial diseases of plants, the author takes up and treats of the occurrence of bacteria in plants, methods of their entrance, inception and progress of disease, reaction of the host, individual and varietal resistance, etc. An extended chapter is devoted to the subject of symbiosis, particular attention being given to that occurring between *Bacterium leguminosarum*, or *Pseudomonas radicola*, and its host plants, the Leguminosae. The author considers the organism in this case a restricted parasite. Other forms of symbiosis are described at some length. The subject of the possibility of the transfer to plants of bacteria known to cause diseases of animals receives attention. The use of germicides in the treatment of seeds and dormant and growing plants is discussed and formulas for numerous fungicides and insecticides are given.

In the second part of the volume the author begins the consideration of specific diseases. Plant diseases due to bacteria are classified by him into 3 groups, vascular diseases, parenchyma diseases without hyperplasia, and cankers, galls, and tumors in which there is a more or less distinct hyperplasia. The diseases described in the present work are the cucurbit wilt due to *Bacillus tracheiphilus*, the black rot of cruciferous plants due to *Bacterium campestre*, and the yellow disease of hyacinths caused by *Bacterium hyacinthi*. Each of these diseases is extensively treated, the symptoms, cause, distribution, characters of the parasite, methods of control, etc., being described. Numerous references to literature are given in connection with the several topics.

[Notes on plant diseases and their control], H. L. RUSSELL (*Wisconsin Sta. Bul.* 218, pp. 20-23).—Notes are given on investigations carried on at the Wisconsin Station on the use of fungicides, tobacco diseases, and the influence of cold on spore germination of certain rusts (E. S. R., 26, p. 342), and a plant disease survey.

It is reported that experiments by O. R. Butler indicate that lime sulphur proved inefficient in controlling the shot-hole fungus of the cherry, and that it also caused in several instances considerable damage in strong sunlight.

The investigations on tobacco diseases by J. Johnson include seed-bed diseases due to *Pythium debaryanum*. The results indicate that soil treatments are not to be recommended, and emphasize the importance of sterilization of the seed bed through burning by fires or with steam. A study was begun on the stem rot of tobacco, and 2 types of fungi, a *Fusarium* and a *Trichothecium*, were found in connection with the disease.

In the report on the plant disease survey, L. R. Jones calls attention to a serious leaf blight of barley due to *Helminthosporium*, losses of 25 to 75 per cent of the crop being noted. Fungus diseases of orchards are said to have been rather uncommon, due to the dry conditions prevailing during the summer. The cherry leaf spot was particularly destructive in some localities, and the crown gall and hairy root are said to be becoming serious. Climatic injuries, due to unseasonable weather conditions, were more or less conspicuous, and the author notes considerable trouble caused by *Septoria* and *Ascochyta* on peas and the *Fusarium* and *Phoma* diseases of cabbages. Attention is called to the necessity for the adoption of precautionary measures against the introduction of such diseases.

Some new or little-known plant diseases in Britain, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London]*, 37 (1912), No. 3, pp. 541-550).—Notes are given on lettuce leaf rot due to *Marssonina panattoniana*, leaf spot of Campanula caused by *Ramularia macrospora*, and a streak disease of sweet peas which is attributed to *Thielavia basicola*.

The lettuce leaf rot is probably identical with that described by Selby (E. S. R., S, p. 990), where the fungus was identified as *M. perforans*.

The streak disease of sweet peas is said to be characterized by brown streaks along parts of the stem and a yellowish tinge in the foliage, which fails to develop properly. The flower buds become yellow and drop without opening, or, in less advanced cases, open and show brownish or yellowish marks on the petals.

An examination of plants affected by this disease showed the presence of the fungus *T. basicola*, and a series of experiments was planned to determine methods of control. In pots which were made acid or alkaline by the addition of fertilizers, sweet peas were planted and half the pots inoculated with the fungus, but in no case did the resulting plants show any indication of disease. In a subsequent experiment the plants after attaining a growth of about 1 ft. in height were heavily overwatered and kept so for several days. The effect of this was very marked. Those in the uninoculated soil were slightly checked in growth, but with proper treatment subsequently as regards watering they recovered, while 75 per cent of those in the inoculated soil showed the development of the disease. It appears that the fungus attacks only the plants that have in any way been weakened, and care should be exercised to secure a good active growth to prevent the appearance of the disease.

**Physalosporina**, a new genus of Pyrenomycetes, N. WORONICHIN (*Ann. Mycol.*, 9 (1911), No. 3, pp. 217-225; *abs. in Bul. Trimest. Soc. Mycol. France*, 27 (1911), No. 3, p. 399).—A description is given of the genus and of the 6 species studied, also a comparative table of the characters of these species, named as follows: *P. megastoma*, *P. obscura*, *P. astragalina*, *P. astragali*, *P. caraganae*, and *P. tranzschelii*.

**New studies on Plasmodiophoraceæ**, R. MAIRE and A. TISON (*Ann. Mycol.*, 9 (1911), No. 3, pp. 226-246, fig. 1; *abs. in Centbl. Bakt. [etc.]*, 2, Abt., 32 (1912), No. 6-12, pp. 328, 329).—The authors here make a fuller report and continuation of previous work (*E. S. R.*, 21, p. 423; 25, p. 43), summarized as follows:

*Tetramyxa parasitica* is one of the Plasmodiophoraceæ, its endophytic development being similar in the main to that of other members of the family. Fungi of the genus *Ligniera*, which also belongs to this family, develop in roots of various plants but do not produce tumescence. The parasite *T. triglochinis* is separated to form a new genus, *Molliardia*.

The relation of the family to the allied forms is also discussed.

**Scleropycnis**, a new generic type, H. and P. SYDOW (*Ann. Mycol.*, 9 (1911), No. 3, pp. 277, 278, figs. 4; *abs. in Bul. Trimest. Soc. Mycol. France*, 27 (1911), No. 3, pp. 401, 402).—A comparison is made of closely related species with this new form, which is described under the name *S. abictina* n. sp.

**A culture study of *Hyalopsora polypodii***, P. DIETEL (*Ann. Mycol.*, 9 (1911), No. 5, pp. 530-533; *abs. in Ztschr. Landw. Versuchsw. Österr.*, 14 (1911), No. 12, p. 1477).—It is claimed as a result of these investigations with *Hyalopsora* on *Cystopteris fragilis*, continued for 2 years, that this fungus can and does normally preserve and perpetuate itself by means of uredospores. These live through the winter and renew the fungus which, so far as its mycelium is concerned in the cases studied, dies out completely before spring. Teleutospores appeared rarely in these experiments and their rôle in the case of this fungus was not ascertained.

**Parasitism of *Nectria* and *Fusicladium***, E. VOGES (*Centbl. Bakt. [etc.]*, 2, Abt., 32 (1912), No. 20-25, pp. 540-551, figs. 2).—Continuing previous studies (*E. S. R.*, 24, pp. 448, 450), the author discusses the nutritive relations of species of *Fusicladium* and *Nectria*, holding as the result of observations by himself and others that while *Nectria* is to be considered only a so-called "wound-parasite" *Fusicladium* is a true parasite.

**Infection studies with Peronospora**, G. VON ISTVANFFI and G. PALINKAS (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 20-25, pp. 551-564).—Continuing previous investigations (E. S. R., 25, p. 751), the authors made a study of Peronospora on beet and grape leaves by artificial infection of separated leaves and of plants growing in the open in wet and in dry weather and at varying temperatures, in order to ascertain the period of inoculation and the influence of relative humidity, temperature, and condition of the plant on its liability to develop the infection.

It was found that rapidity of development was variable, and that high relative humidity of the air, high water content of the plant, and sudden lowering of temperature all tended to render the plant more open to attacks by the fungus. Dryness tended to retard advance of the disease when already present.

**The infection of forage grasses by ergot**, E. GALIN (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 5, pp. 189-191).—It having been claimed that the spores of certain ergots, especially that of *Lolium*, require passage through the intestinal tract of insects to secure their germination, the author conducted some experiments with about 30 specimens of *L. perenne*, *Arrhenatherum elatius*, *Phleum pratense*, and *Holcus lanatus* to determine the rôle of insects in the spread of ergot among these grasses.

Inoculation experiments showed that ergot could be readily produced, but that insects played a secondary rôle, merely acting as carriers of the spores as in pollination, and that they were not essential to the dissemination of the fungus or to the infection of the host plant.

**The use of iron sulphate for the control of the rust of plants**, C. FUSCHINI (*Rivista [Conegliano]*, 4. ser., 17 (1911), No. 19, pp. 443-446; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, p. 2600).—A preliminary account is given of experiments by the author on the application of considerable quantities of iron sulphate to the soil for the prevention of the rusts of wheat and beans.

In the experiments iron sulphate was added to the soil at the rate of 1.6 cwt. per acre for wheat and 2.4 cwt. for beans, after which the seed was planted. No difference could be noted for the wheat the following season, as there was but little rust in the vicinity. With the beans there was a considerable increase in weight of both the seed and plants. This is attributed to the use of the iron sulphate, which induced a much more vigorous vegetative growth.

The author is of the opinion that the application of iron sulphate before planting may be of use in preventing rusts in various crops through the general increase in the vigor of the plants, so that they can better resist the attacks of fungi.

**A practical view of root rot of beets**, H. BRIEM (*Ztschr. Zuckerindus. Böhmen*, 36 (1911), No. 1, pp. 23-25).—After a brief discussion of some opinions regarding the nature of this disease and remedies therefor, the author states that his experience leads him to the conclusion that a plentiful supply of lime in the soil in available form and the thorough aeration of the soil by means of the hoe are the most effective means for combating this disease.

**Rice blight**, J. S. COLLIER (*Illinois Sta. Circ. 156*, pp. 19, figs. 11).—In continuation of a previous report (E. S. R., 24, p. 743) and preliminary to an extended statement giving the entire data and the results of the experiments, the author gives an account of his investigations on rice fields in Arkansas.

The disease seems to be wholly a physiological one, and is not to be confounded with blights caused by insects or fungi. The root is the part of the plant affected, and the nutrition of the plant is so impaired that the grain does not develop. The results show that a good physical condition of the soil, with aeration at the proper time, will prevent blight. It is not caused by deep

flooding, and moving water diminishes the amount. Mineral salts had no effect on the disease, nor did the addition of ground limestone, aside from the general effect it had on the growth of rice through improved biological conditions.

From the results of the experiments, the author suggests that the disease may be controlled by the preparation of the soil and the seeding of the rice when the soil is in good condition to work. Rice should be flooded for the first time when it is about 8 in. high, barely covering the land with water for 6 or 7 weeks. At the time the head is forming in the "boot" the water should be drained off and the soil aerated for 2 or 3 weeks, after which the fields are again to be flooded to a depth of about 3 in. for 4 or 5 weeks. The water should be gradually drained off until time to dry for harvest.

**Preliminary study of the red rot of sugar cane in the Bombay Presidency,** G. S. KULKARNI (*Dept. Agr. Bombay Bul.* 44, 1911, pp. 8, pls. 3).—The red rot disease due to *Colletotrichum falcatum* has become a serious trouble in some of the cane-growing regions of India. The distribution of the disease and symptoms are described.

From the author's observations it appears that the infection is most commonly through the use of diseased cane for planting. For the prevention of the disease it is urged that the sets be carefully examined and only those that show white pith at the cut ends be selected for planting. Any that show the slightest reddening should be destroyed.

**The life history of the plum rust in England,** F. T. BROOKS (*New Phytol.*, 10 (1911), No. 5-6, pp. 207, 208; *Gard. Chron.*, 3, ser., 50 (1911), No. 1295, p. 292; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, pp. 2693, 2694).—A severe epidemic of plum rust (*Puccinia pruni*) is said to have prevailed in fruit plantations of Cambridgeshire, England, the trees often being prematurely defoliated. There has been some doubt as to how the fungus survives the winter. Both uredospores and teleutospores are produced on plum leaves, but experimental proof is lacking that they can survive the winter and infect the leaves of the plum the following season.

Experiments by the author, in which aecidiospores of *Aecidium punctatum* from *Anemone coronaria* when placed on plum leaves produced the disease, confirm the claim of the heteroecism of *P. pruni*. The mycelium is perennial in *Anemone* and gives rise to crops of uredospores year after year, so that a few plants attacked by the aecidium are sufficient to account for the recurrence of the plum rust. After the first crop of uredospores has been produced on the plum leaves the fungus spreads rapidly on that host. Plants of *Anemone* affected by the fungus are said to have more fleshy leaves and to flower very rarely.

The eradication of plants of *A. coronaria* affected by the aecidium is suggested as a means of controlling this disease.

**Experiments on the control of chlorosis of fruit trees,** G. RIVIÈRE and G. BAILLIACUE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 11, pp. 340-344).—Experiments are reported on the treatment of pear trees for chlorosis.

The trees were fed a solution of pyrophosphate of iron with ammonium citrate through holes near the base of their trunks. Inserted in the holes were tubes connected with vessels holding the solutions of the chemical. The solution, it is said, did not precipitate tannin and close the vessels of the wood, as is the case when some other iron compounds are used. Ten-year-old pear trees took up more than 14 liters of the solution, corresponding to 0.7166 gm. of the pyrophosphate of iron, in 87 days of the experiment. The chlorotic appearance of the trees was changed to a healthy one.

**Resistance to chlorosis.** A. VERNEUIL and R. LAFOND (*Rev. Vit.*, 36 (1911), No. 927, pp. 321-326).—During 1911 chlorosis appeared very destructive in certain regions of France to varieties of grapes hitherto considered resistant even when planted in lime soils. The season was a very rainy one and followed an unusually wet year. Previously, chlorotic vines treated with iron sulphate had given good crops, but in 1911 all failed.

A study was made of the vines, and especially of the maximum quantity of lime in the soils where the more resistant varieties could grow without showing chlorosis. The resistance to lime was found to vary with the different varieties, and the depth and character of the subsoil were found to influence materially the growth of the vines. Some varieties of grapes were found to tolerate as much as 45 per cent of lime in the soil, while the ordinary Riparia stock will not withstand much more than 10 per cent. In deep rich soils that are not excessively moist the tolerance was even higher. The authors claim that in the establishment of vineyards which are to remain for many years the depth and character of the subsoil must be taken into consideration.

**Infection of grapes by downy mildew.** J. J. KRANKOFF (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 11, pp. 334, 335).—A brief account is given of spraying experiments for the control of mildew, which in 1911 was successfully combated by early and repeated sprayings. The application was made almost exclusively to the upper side of the leaves, thus confirming the conclusions of Ravaz and Verge (*E. S. R.*, 26, p. 550).

**The conditions necessary for the appearance of downy mildew.** L. RAVAZ and G. VERGE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 10, pp. 296-300).—A study has been made of the relation of temperature to the appearance of the conidia of the downy mildew, *Plasmopara viticola* (*E. S. R.*, 26, p. 851). Infested leaves were kept in thermostats and the temperature and time required for the appearance of the characteristic white spots of the mildew were noted.

None appeared at temperatures below 13° C., but they did show after 20 hours at that temperature. At about 20° the development is most rapid, a single day or night with this temperature accompanied by suitable humidity being all that is needed to induce a rapid growth. The development is somewhat slower at higher temperatures. In the spring of the year the temperature and other conditions at Montpellier are said to be seldom suitable before May 27 to promote the rapid spread of the fungus, while in autumn the conditions are usually very favorable and frequent successive invasions of the fungus are to be expected.

**Experiments in the treatment of grapevine mildew in the Bombay Presidency.** W. BURNS (*Dept. Agr. Bombay Bul.* 45, 1911, pp. 15, pls. 4).—An account is given of spraying experiments in which Bordeaux mixture was used for the control of the downy and powdery mildews of grapes. Two years' work has shown that thorough and timely spraying greatly reduces the loss commonly due to these fungi. The author notes the apparent resistance of one variety to mildew and frost injury.

**The relation of meteorological conditions to diseases of the mulberry.** G. ARNAUD and F. LAFONT (*Ann. École Nat. Agr. Montpellier, n. ser.*, 11 (1912), No. 3, pp. 169-215, figs. 25).—A report is given on the relation of weather conditions to attacks of *Nectria cinnabarina* and *Coryneum mori* on the mulberry, the studies on the former having been carried on at Montpellier, while the report on the latter is largely based on the work of Butler (*E. S. R.*, 22, p. 51). So far as the *Nectria* is concerned, and probably the same is true for the *Coryneum*, the authors believe that their occurrence as parasites on the mulberry is associated with the injury of the developing buds by late spring frosts. The

diseases at times are very destructive, especially where the mulberries are pruned closely.

Notes are also given on mulberry diseases due to *Bacterium mori*, *Gibberella pulicaris*, and *Botrytis cinerea*.

**Banana diseases.** W. FAWCETT (*West India Com. Circ.*, 27 (1912), No. 351, pp. 125, 126).—Accounts are given of the Panama disease due to *Ustilaginoidella musaperda* (E. S. R., 25, p. 349); the Surinam disease of bananas, which occurs with the Panama disease, but is distinct from it; the "Moko" plantain disease, due to *Bacillus musæ* (E. S. R., 25, p. 148); and the root disease caused by a species of *Marasmius*.

**The Panama disease of the Gros Michel banana in Surinam.** A. W. DROST (*Dept. Landb. Suriname Bul.*, 26, 1912, pp. 45, pls. 11).—According to the author's investigations, this disease was present in Surinam before the Gros Michel or Jamaica banana had been introduced. He claims that it is caused by the fungus *Leptospora musæ*.

The fungus penetrates through the root hairs, following the central bundle of the roots, and then spreads to the bulb and ascends into the vascular bundles of the leaf stalk. It attacks principally the bundles where suckers have been cut from the mother plant under the surface of the soil, and as a rule it does not reach the blade of the leaf. Besides perithecia, it is said to produce spores of a *Cephalosporium* and of a *Fusarium* type. Inoculations from pure cultures gave positive results.

The fungus was found to attack different varieties of *Musa*. It lives for a long time in the soil, from which it may infect new plantings. On this account soils once infected are said to be always unfit for Gros Michel banana cultivation. The moisture content of the soil is said to influence the susceptibility of bananas to the disease. The varieties of *M. paradisiaca* vary in their liability to infection by it, some varieties being practically immune.

**The banana disease** (*Jour. Jamaica Agr. Soc.*, 16 (1912), No. 2, pp. 90-92).—An account is given of the occurrence of the Panama banana disease in Jamaica.

**Die-back or exanthema of citrus trees.** E. O. ESSIG (*Pomona Col. Jour. Econ. Bot.*, 1 (1911), No. 2, pp. 73-82, figs. 2).—The author has brought together much of the information concerning die-back of citrus trees, which it is held is due to physiological causes.

**The withertip disease in Florida.** P. H. ROLFS (*Pomona Col. Jour. Econ. Bot.*, 1 (1911), No. 3, pp. 107, 108).—A brief account is given of the withertip of citrus trees as it occurs in Florida, and the author notes its frequent occurrence in California. For the control of this disease the best method in Florida is said to consist of thorough orchard sanitation followed by vigorous pruning out of the affected branches.

**New fungi occurring on orange leaves.** H. REHM (*Pomona Col. Jour. Econ. Bot.*, 1 (1911), No. 2, p. 106).—Technical descriptions are given of *Mycosphærella lageniformis* n. sp. and *Scleroplea aurantiorum* n. sp., which occur on orange leaves in southern California.

**Notes on *Scleroplea aurantiorum* and *Mycosphærella lageniformis*.** C. W. METZ (*Pomona Col. Jour. Econ. Bot.*, 1 (1911), No. 3, pp. 109, 110, fig. 1).—Supplementing the technical descriptions of these fungi (see above), the author gives an account of their attack on the host plants. The leaves upon which the fungi are found resemble those affected with withertip, due to *Colletotrichum gloeosporioides*. Both species are often found on the same leaf, but the larger perithecia of *Scleroplea* usually serve to distinguish them.

The author believes that the information at hand is not sufficient to justify conclusions relative to the economic importance of the fungi, whether they are both parasitic or not.

A new *Mycosphærella* from Saxony, W. KRIEGER (*Ann. Mycol.*, 9 (1911), No. 3, p. 216; *abs. in Bul. Trimest. Soc. Mycol. France.*, 27 (1911), No. 3, p. 398).—The new species, described and named *M. virgaureæ*, is said to have been found in May, 1909, on leaves of *Solidago virga aurea* of the previous year's growth.

Myological notes, F. VON HÖHNEL (*Ann. Mycol.*, 9 (1911), No. 3, pp. 213-216; *abs. in Bul. Trimest. Soc. Mycol. France.*, 27 (1911), No. 3, p. 398).—The results are here given of a study of *Coniodictyum chevalieri*, which is alleged to cause galls on twigs and leaves of *Zizyphus* and to be identical with the fungus otherwise named *Hyalodema cransii* (E. S. R., 24, p. 252).

The slime disease of *Cyathea medullaris*, P. SORAUER (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 1, pp. 42-48, pl. 1).—This is a study by the author of a liquefying disease of this fern, said to be somewhat similar to gummosis, and associated with the presence of a fungus which is described and placed in the genus *Nectria*.

The Japanese chestnut at the experiment station at Lindois, A. PRUNET (*Bul. Soc. Nat. Agr. France.*, 72 (1912), No. 2, pp. 131-137; *Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 8, pp. 522-524; *abs. in Rev. Sci. [Paris]*, 50 (1912), I, No. 9, p. 285).—In continuation of previous observations on the resistance of Japanese chestnuts to the black canker or root disease (E. S. R., 23, p. 49), the author reports experiments in which trees from 1 to 4 years old of common and Japanese chestnuts were planted in localities known to be badly infested as well as in a region where the disease was less prevalent.

Of 89 trees of the common chestnut planted in the badly diseased area, 86 died and 3 were badly infested. Of 48 common trees planted in less infested soils 33 died. In noninfected regions all remained sound. No Japanese chestnut trees were lost due to attacks of this disease, although 90 were planted in different situations.

A disease of the beech, P. MAGNUS (*Sitzber. Gesell. Naturf. Freunde Berlin*, 1911, No. 10, pp. 436-439).—The author calls attention to a disease observed on beech in the Rhine region which quickly killed trees from 70 to 80 years old, and which he declared to be caused by a saprophytic fungus, *Agaricus mucidus*, also called by several other names. The question as to the proper systematic placing of the species is also discussed.

Fungus galls on the beech, M. MÖBIUS (*Ber. Senckenb. Naturf. Gesell.*, 42 (1911), No. 1, pp. 7-12, figs. 3).—A description is given of *Cyllaria darwinii*, a fungus that causes galls on twigs and branches of *Fagus betuloides*, a beech native of the Southern Hemisphere.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

A history of British mammals, G. E. H. BARRETT-HAMILTON (*London*, 1911, vol. 1, pls. 4, pp. 25-32+169-208, pls. 4, figs. 5; 5, pp. 33-40+209-248, pls. 3, figs. 5; 6, pp. 41-48+249-263, pls. 3, fig. 1; vol. 2, pls. 6, pp. 24, figs. 20; 7, pp. 25-72, pls. 4, figs. 3; 8, pp. 73-120, pls. 5, figs. 2; 9, pp. 121-168, pls. 4, figs. 6; 10, pp. 169-216, pls. 4, figs. 11).—This is a continuation of the work previously noted (E. S. R., 25, p. 150).

The Vespertilionidæ are taken up in parts 4 and 5 and the Rhinolophidæ in parts 5 and 6 of volume 1. Volume 2 deals with the land mammals. The order Insectivora is first taken up; the Talpidæ, or common moles, are dealt with in parts 6 and 7; the Erinaceidæ, or true hedgehogs, in parts 7 and 8; the Soricidæ, or shrews, in parts 8 and 9; and the Rodentia in parts 9 and 10.

Some common mammals of western Montana in relation to agriculture and spotted fever, C. BIRDSEYE (*U. S. Dept. Agr., Farmers' Bul.* 484, pp. 46, figs. 34).—This bulletin is based on investigations conducted in western Montana for several years, especially in the Bitter Root Valley, in cooperation with the Bureau of Entomology of this Department and with the Montana Station. A circular relating to the subject has been previously noted (*E. S. R.*, 25, p. 756).

The author concludes that the most feasible ways of controlling Rocky Mountain spotted fever, which is transmitted from wild animals to human beings by the bite of infected ticks, are: "(1) To educate the inhabitants of infested localities in a belief in the 'tick theory'; (2) to lessen the number of wood ticks, by (a) keeping domestic stock, the principal hosts of the adult ticks, tick free and (b) lessening the number of native rodents, the necessary hosts of the younger states of the ticks; and (3) to destroy those native rodents which may serve as a source of continued reinfection of the ticks."

Directions for poisoning and otherwise destroying rodents are presented.

Analysis of the results of 87 fecal examinations of sheep dogs for evidences of parasitism, W. D. FOSTER (*Science, n. ser.*, 35 (1912), No. 901, pp. 553, 554).—This is a brief statement of the results of examinations of collie and sheep dogs imported to this country, made while in quarantine.

All the dogs examined that were found to be infested with tapeworms were given a suitable tæniacuge. Of 87 dogs examined, 50 were infested with parasitic worms, and of these 28 were infested with nematodes only, while the remainder were infested with tapeworms of 1 or more species or of tapeworms and nematodes. Of the 22 dogs infested with tapeworms, 7 were infested with *Tania hydatigena*, 8 with *T. pisiformis*, 4 with *Dipylidium caninum*, 2 with *Multiceps serialis*, and 8 with unidentified *Tania*.

The author is inclined to believe that the small percentage of infestation shown in the examination is the result of the greater care bestowed on valuable animals.

A new species of trematode from the muskrat, *Fiber zibethicus*, F. D. BARKER and J. W. LAUGHLIN (*Trans. Amer. Micros. Soc.*, 30 (1911), No. 4, pp. 261-274, pl. 1).—The trematode here described as *Notocotyle quinqueseptemlineata* n. sp., is one of a large number of trematodes, representing several species, that were found in the alimentary canal of muskrats, near Calloway, Nebr.

Microbes killing mice and rats, A. VOYTKEVICH and A. KOLENEV (*Vĕstník Bakt. Agron. Stantsii V. K. Ferrĕin*, 1911, No. 18, pp. 97-153).—An extended discussion of the subject.

Raticide—Azoa, S. S. MERESHKOWSKY (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 62 (1912), No. 1-2, pp. 72-75).—The author's investigations led him to conclude that the commercial preparation known in England by the name Raticide and in America as Azoa can not be recommended for use in destroying rats.

The food of birds of India, C. W. MASON and H. MAXWELL-LEFROY (*Mem. Dept. Agr. India, Ent. Ser.*, 3 (1912), Jan., pp. 371).—This paper is said to be a compilation from various sources of what little is known of the food of Indian birds at the present time. It also contains numerous field notes on the food of the common species of the plains, together with the records of 1,325 stomachs examined in the laboratory.

Chronology and index of the more important events in American game protection, 1776-1911, T. S. PALMER (*U. S. Dept. Agr., Bur. Biol. Survey Bul.* 41, pp. 62).—This bulletin contains a brief historical summary of game legislation in this country and related matters, a chronology from 1776 to 1911 of State and Federal legislation and other data of interest, and a subject index to the chronology.

A contribution to the physiology and morphology of the digestive apparatus of insects, C. SCHLÜTER (*Ztschr. Allg. Physiol.*, 13 (1912), No. 3, pp. 155-209, pls. 3).—This account includes a bibliography of 42 titles.

Insect pest survey, H. L. RUSSELL (*Wisconsin Sta. Bul.* 218, pp. 23-25).—It is stated that following the nearly complete loss of fruit by the late spring freeze in 1910, the majority of fruit insects were left without their normal food, and, consequently, but few completed their life cycle for winter hibernation. The codling moth and plum curculio were almost entirely eliminated as destructive factors in fruit growing in some regions. The pear slug is said to be reaching proportions where much damage is annually occasioned to the cherry and plum. The apple aphid was unusually abundant during the year, and the growth of young trees stunted thereby. The cottony maple scale was again abundant, and the asparagus beetle was reported from several sections. Both the onion thrips and onion maggot are causing severe losses in the trucking regions in the southeastern part of the State. Locusts or grasshoppers were unusually destructive in some sections, likewise the blister beetles, which have caused no little injury to alfalfa and vetch. The damage by blister beetles is partly atoned for by the good which their larvae accomplish in feeding on grasshopper eggs which they destroy by the thousands.

Farmers' foes and their remedies (*Dept. Agr. Brit. Columbia Bul.* 24 [1908], pp. 200, figs. 73).—This compilation deals largely with insect pests occurring in British Columbia and remedial measures therefor. A chapter on plant diseases is included.

Insect pests in the West Indies in 1911 (*Agr. News [Barbados]*, 11 (1912), No. 254, pp. 26, 27).—This is a brief account of the more important insect pests of the year in the British West Indies.

Insect notes for the year 1910-11, P. L. GUPPY (*Bd. Agr. Trinidad Circ.* 3, 1911, pp. 3-14, figs. 2).—This paper, which is a more extended account than that previously noted (*E. S. R.*, 25, p. 357), deals with the insect enemies of cacao, rubber, tobacco, cotton, and other crops.

Miscellaneous notes, F. W. URICH (*Bd. Agr. Trinidad Circ.* 3, 1911, pp. 15-25, fig. 1).—Miscellaneous papers are here presented. The first, which relates to ants on cacao estates, includes a preliminary list of 69 forms of Trinidad ants; the second deals with rats and other mammals on cacao estates; the third consists of notes on insecticides, etc.

[Destructive insects, 1910] (*Bd. Agr. and Fisheries [London], Ann. Rpt. Intel. Div.*, 1910-11, pt. 2, pp. 27-38, pl. 1).—Among the more important insects considered in this report are the grapevine phylloxera, the large larch sawfly (*Nematus crichsonii*), the potato tuber worm, the cherry fruit fly (*Rhagoletis cerasi*), the narcissus fly (*Merodon equestris*), etc.

Report of the entomological section of the Wellcome Tropical Research Laboratories, H. H. KING (*Rpt. Wellcome Research Labs. Gordon Mem. Col. Khartoum*, 4 (1911), *B. Gen. Sci.*, pp. 95-150, pls. 7, figs. 30).—The author first reports upon animals injurious to man and animals, including mosquitoes and their control; blood-sucking flies other than mosquitoes, particularly tabanids, with a list of blood-sucking flies recorded from the Anglo-Egyptian Sudan with the localities in which they are known to occur; Cestridæ; and ticks. The animals injurious to farm and garden crops considered include the Dura stem-borer (*Scsamia cretica*), the black or greasy cutworm (*Agrotis ypsilon*), the asal fly (*Aphis sorghi*), the cotton stem borer (*Sphenoptera neglecta*), the melon weevil (*Baris tragardhi*), the melon stem borer (*Apomecyna binubila*), the melon leaf beetle (*Aulacophora foveicollis*), the diamond-back moth (*Plutella maculipennis*), the cabbage bug (*Bagrada picta*), the rigla gall weevil

(*Baris lorata*), the fig stem-boring beetle (*Sinoxylon sudanicum*), white ants, and the black garden ant (*Aphnogaster barbara*).

The plants diseases ordinance of 1910 is appended to the report.

**Suppression of the cotton white scale in Piura, C. H. T. TOWNSEND** (*Bol. Div. Fomento [Peru]*, 9 (1911), No. 3, pp. 1-7).—This paper briefly considers the cotton white scale (*Hemichionaspis minor*), the cotton square weevil (*Anthonomus* sp., probably *vestitus*), the cotton strainer (*Dysdercus ruficollis*), etc.

**Insect pests of jute, H. L. DUTT** (*Dept. Agr. Bengal, Quart. Jour.*, 5 (1911), No. 2, pp. 107-110).—This important fiber crop has several important insect enemies, including leaf feeders and capsule and stem borers. Particular mention is made of the indigo caterpillar (*Laphygma crigua*), the jute semilooper (*Cosmophila sabulifera*), and the "behar" hairy caterpillar (*Diaerisia obliqua*).

**The enemies of rye, P. NOEL** (*Bul. Lab. Régional Ent. Agr. [Rouen]*, 1911, No. 4, pp. 4-7; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, p. 2623).—The author lists 37 insect enemies of rye.

**Fruit flies and other insects attacking cultivated and wild fruits in New South Wales, W. B. GURNEY** (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 1, pp. 75-80, pls. 2, figs. 9).—This third paper (E. S. R., 26, p. 150) deals with the island fruit fly (*Trypeta musca*), the tomato fly (*Lonchaea splendida*) which sometimes attacks citrus fruit, the ferment fly (*Drosophila obscura*) which attacks all classes of damaged fruit, fruit-eating beetles of the genus *Carpophilus*, and the identification of fruit fly maggots.

**New control methods for the pear thrips and peach tree borer, E. L. MORRIS** (*California Sta. Bul.* 228, pp. 367-374, figs. 6).—The investigations of control measures for the pear thrips here reported are based on experiments conducted during 1910 and 1911 in a pear orchard near San José, Cal. Experiments carried on in 1910, in which applications of whitewash were made in different amounts by spraying before the buds were open sufficiently to admit the thrips, resulted in finding the number of blossoms to be in direct proportion to the amount of whitewash applied. The trees which had a thin coating of whitewash had very few blossoms, while those which had a very thick coating of whitewash had an abundance. The amount of fruit corresponded to the number of blossoms.

In 1911 the experiment was repeated on a larger scale. An application of lime made with a view to showing that the whitewash would have the same beneficial effect when applied a week or more before the buds open, as when applied at the time of opening, was rendered worthless by an untimely down-pour of rain. A second application made just as the buds were beginning to open gave results similar to those of 1910. All the sprayed trees came into full bloom and the unsprayed trees blossomed very feebly; the fruit corresponded very closely to the blossoming, the sprayed trees averaging 8 times as much as the unsprayed trees.

Eighty lbs. of quicklime was used to make 100 gal. of spraying material, the whitewash being strained through a 1/14 in. mesh wire screen and the same sized screen used on the suction hose of the pump. The ordinary Bordeaux nozzles worked well, but it was necessary to enlarge slightly the opening in the disks of the Vermorel type nozzles.

The work with the peach tree borer (*Sanninoidea pacifica*), an insect of much economic importance in the horticultural district around the southern arm of San Francisco Bay, was conducted at Berryessa, Cal. Experiments by the author led to the use of hard asphaltum, grades "C" and "D" with good

results. "This was applied early in the spring to badly infested trees from which the borers had not been dug. It was found that a thick heavy coating prevented both the issuance and the entrance of about 95 per cent to 98 per cent of the insects, the degree of efficiency depending upon the thoroughness of the application. Asphaltum does not penetrate, crack, deteriorate, or bind the tree, since it yields to the slightest pressure. Four years of experimenting have not shown the least injury." The material while warm was applied from 5 in. below to 5 in. above the ground by means of a brush. Two coatings are said to be generally sufficient, unless the bark is very rough. The borer is seldom uniformly distributed over an orchard, and it is not necessary that all of the trees be treated with asphaltum, although it is necessary to examine them carefully in order to discover those that are infested. The author has also used asphaltum to a limited extent for covering wounds and for grafting.

**Roaches and their extermination by the use of sodium fluorid (NaF),** M. F. GATES (*U. S. Naval Med. Bul.*, 6 (1912), No. 2, pp. 212-214).—The author finds that the cockroach can be quickly, cheaply, and completely eliminated from ships or houses by the use of sodium fluorid. Since the insects do not take it voluntarily but lick it off their feet it should be dusted thinly but widespread where they are most numerous. It must be kept dry in order to adhere to the feet of the roaches.

**The rice grasshopper (*Hieroglyphus banian*),** L. C. COLEMAN and K. K. KANNAN (*Dept. Agr. Mysore, Ent. Ser. Bul.*, 1, 1911, pp. 52, pls. 5, figs. 4).—This is a detailed account of studies of the rice grasshopper, including its life history and preventive and remedial measures.

**South American Acridoidea,** L. BRUNER (*Ann. Carnegie Mus.*, 8 (1911), No. 1, pp. 5-177).—Two hundred and three species are here considered of which 10 genera, 61 species, and 1 variety are described as new to science.

**Information relative to the enemies of the olive in the Province of Jaén,** L. NAVARRO (*Bol. Agr. Téc. y Econ.*, 3 (1911), No. 33, pp. 797-809).—*Phlaothrips olea* appears to be a most important insect enemy of the olive in the Province of Jaén, which is located in the southern part of Spain.

**Kala-azar and the bedbug (*Lanct* [London], 1912, I, No. 8, p. 520).**—A discussion of some recent investigations.

**Test sprayings for the gloomy scale (*Chrysomphalus tenebricosus*),** Z. P. METCALF (*Jour. Econ. Ent.*, 4 (1911), No. 6, pp. 515-521).—"The gloomy scale is the most important insect enemy of shade trees in North Carolina, and is well distributed over all this State south and east of the mountains. Its importance is due to 2 factors, the enormous rapidity with which it breeds and the fact that it is all but completely confined to the soft maples which have been so largely used for shade purposes in our cities and towns."

The experiments here reported led the author to conclude that any of the soluble oils 1:8 or 1:10 are satisfactory remedies if used while the tree is dormant, one application being sufficient for several years where the infestation is slight or moderate. Where the scale is serious 2 or more applications are advisable.

"None of the commercial lime-sulphur washes were as satisfactory for controlling the gloomy scale as the soluble oils. This we believe is accounted for by the fact that the dorsal scale of this insect is thicker and applied more closely to the ventral scale than is the case in the San José scale. Our observations would lead us to believe that the oils owe their superior killing powers to the fact that they remain moist much longer than the lime-sulphur preparations and are thereby enabled to creep in between the dorsal and ventral scales. The corrosive lime-sulphur washes do not seem to be able to penetrate the thick

dorsal scale of this insect. Some of the lime-sulphur washes gave fair results and if spraying for the gloomy scale could be repeated year after year, as in the case of the San José scale, they might be recommended. But with shade trees this is usually not practicable. None of the spring applications were at all satisfactory, and it was impossible to see that any of the trees sprayed in the spring had been benefited to any marked degree."

**Apropos of *Aleyrodes olivinus*,** C. CAMPBELL (*Abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 2 (1911), No. 7, p. 1836*).—The author calls attention to the fact that *A. olivinus*, described by Silvestri (E. S. R., 26, p. 149) as a new olive parasite in central and southern Italy, and recently recorded by Chapelle as a new olive pest in Spain, is not only found in Italy but also in Tunis, where the author has himself found specimens. He has also noted its presence in Smyrna.

**The larger canna leaf-roller (*Calpododes ethlius*),** F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ. 145, pp. 10, figs. 8*).—During the year 1911 the canna leaf-roller was abundant in various parks in the District of Columbia, at West Grove, Pa., and at points as far south as Orlando, Fla. This circular describes its injury and method of attack, distribution, stages, life history and habits, natural enemies, and methods of control.

The caterpillars of this butterfly appear to attack only plants of the genus *Canna*, when these are obtainable, at times utterly destroying luxuriant plants. Attention is attracted to its injury by the large irregular areas which are cut away from the margin of the canna leaves. The larva cuts a small, more or less oblong strip about  $\frac{1}{2}$  in. long from the edge of the leaf and folds it over on the lower surface. Within this nearly flat flap it lies concealed, feeding above and below its retreat. As it increases in size the larva makes large incisions in the leaf's edge with a correspondingly large flap, and later forms large tubular retreats. A portion of the lower side of the leaf is at times folded over the upper surface. On August 24, 1907, this pest was present in all stages in great abundance on canna at Orlando, Fla.

The species, which is of tropical origin, appears to be killed by severe frosts. So far as can be learned it is known to exist permanently in the United States only in the Gulf States, South Carolina, and Porto Rico. It also inhabits Cuba and Jamaica, and in South America occurs as far south as Argentina.

The eggs, which are laid singly and separately, sometimes in groups of from 5 to 7 on the undersurface of the leaves, hatch in from 4 to 6 days. The larva is said to pass through 5 stages. The egg parasite *Pentarthron minutum* has been observed to be an important enemy at Orlando, Fla. Handpicking has been successfully practiced in parks at Washington, D. C., as has the squeezing of the leaves with gloved hands. Paris green and arsenate of lead with or without Bordeaux mixture can be used with little danger of poisoning, although their use appears to be undesirable where children have access to the plants.

**Combating the cochylis and eudemis moths,** G. DALMASSO (*Staz. Sper. Agr. Ital., 43 (1910), No. 7-9, pp. 593-645*).—This is a report of experimental studies of remedial measures for these grapevine pests, conducted at Milan.

**A note on some mucedines observed on *Cochylis ambiguella*,** G. FRON (*Bul. Trimest. Soc. Mycol. France, 27 (1911), No. 4, pp. 482-487, pl. 1*).—This paper relates chiefly to *Botrytis bassiana* (= *Spicaria bassiana*) and *Spicaria verticillioides* n. sp.

**Observations on lamp traps for the cochylis moth,** V. VERMOREL (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 32 (1911), No. 29, p. 70; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 2 (1911), No. 7, pp. 1819, 1820*).—In experiments conducted by the author an acetylene lamp was placed in a tray at one end of a large closed room, 50 meters (164 ft.) long, and after-

wards cochyliis and eudemis moths, which had been bred in captivity, were liberated at different distances from the lamp. When liberated not more than 25 meters from the lamp the cochyliis moths flew to the lamp and were drowned in the tray: the eudemis moths seemed to be unaffected by the light at that distance.

**The potato moth**, A. H. COCKAYNE (*Jour. New Zeal. Dept. Agr.*, 2 (1911), No. 4, pp. 179-186, figs. 4).—This is an account of the life history and of control measures for the potato tuber worm, a severe outbreak of which was experienced in the South Island, New Zealand, the 1911 crop being very materially affected in certain localities.

**The light brown apple moth** (*Tortrix* [*Cacæcia*] *responsana*), C. FRENCH (*Jour. Dept. Agr. Victoria*, 10 (1912), No. 2, pp. 111-113, fig. 1).—This moth, which is found in most parts of Victoria, is said to be a very destructive insect, attacking almost any kind of garden plant, as well as apples and other fruits.

**The Microlepidoptera of the vineyard**, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est Centre)*, 32 (1911), No. 15, pp. 448-469, pl. 1, fig. 1).—This is a summarized account of information relating to the grapevine pyralid (*Enophytia pilleriana*), the cochyliis (*Cochylis ambiguella*), and the eudemis (*Polychrosis botrana*) moths.

**The "schlaffsucht" of the meal moth caterpillar**, E. BERLINER (*Ztschr. Gesam. Getreidew.*, 3 (1911), No. 3, pp. 63-70).—This paper reports experiments in which the caterpillars of the meal moth were inoculated, moistened, and fed with the causative bacterium. It was found to possess a high virulence, 100 per cent mortality resulting in some instances, both when applied externally and when ingested.

**The Mycetophilidæ of North America. Part III**, O. A. JOHANNSEN (*Maine Sta. Bul.* 196, pp. 249-328, pls. 5).—In this third part (*E. S. R.*, 23, p. 762) of the author's work on the fungus gnats, the subfamily Mycetophilinæ is dealt with. The work includes tables for the separation of the genera and species. Numerous species are described as new to science.

"As far as known all of the species of this subfamily pass the earlier stages in mushrooms or decaying wood. The larvæ of several species of *Exechia* and of *Mycetophila* are occasionally found in cultivated mushrooms, *M. punctata*, quite frequently. This species is also particularly common in wild mushrooms, at times very few plants escaping infestation. Mushroom growers need expect but little trouble from these pests if they will provide their cellars with fine mesh wire screens."

**The identity of the better known midge galls**, E. P. FELT (*Ottawa Nat.*, 25 (1912), Nos. 11, pp. 164-167; 12, pp. 181-188).—This is a descriptive list of some of the earlier named species of cecidomyiids.

**New West Indian gall midges**, E. P. FELT (*Ent. News*, 23 (1912), No. 4, pp. 173-177).—In this paper the author describes as new to science *Bruggmanniella pisonia*, reared from the stems of *Pisonia nigricans*; *Mycodiplosis pulvinaria*, the larvæ of which were found preying upon *Pulvinaria pyriformis*; *Arthrocnodax meridionalis*, reared from Eriophyes galls, including galls of *Eriophyes gossypii* on Sea Island cotton; and *Hyperdiplosis producta*, reared from what presumably were mite galls in the inflorescence of *Stachytarpha jamaicensis*. All were from St. Vincent Island.

**Second contribution to the knowledge of the Brazilian species of Simulium**, A. LUTZ (*Mem. Inst. Oswaldo Cruz*, 2 (1910), No. 2, pp. 213-267, pls. 4).—In this second paper (*E. S. R.*, 23, p. 762), which is principally systematic, 17 species are described as new to science.

**Dr. A. Lutz's studies of Brazilian Simuliidæ**, F. KNAB (*Proc. Ent. Soc. Wash.*, 13 (1911), No. 3, pp. 172-179).—The first part of the work reviewed in

this paper has been previously noted (E. S. R., 23, p. 762); the second part is noted above.

**The evolution of *Trypanosoma evansi* through the fly: *Tabanus* and *Stomoxys*, F. S. H. BALDREY (*Jour. Trop. Vet. Sci.*, 6 (1911), No. 3, pp. 271-282, pls. 2).—In the observations reported many hundreds of flies were used and 500 slides examined, and in no case was development of the parasite further advanced than in the spore or piroplasmic form observed. "This appears to indicate that the development was either arrested or that the cycle is completed in another way, probably through the egg of the fly or by a second cycle through a mammalian animal."**

**Observations of the tachinid parasite of the nonne moth (*Parasetigena segregata*), F. TIMAEUS (*Naturw. Ztschr. Forst u. Landw.*, 9 (1911), No. 2, pp. 89-95, fig. 1).—This paper, which includes a note by K. Escherich, under whose direction the studies were conducted, deals with the incubation period of the eggs and the entrance of the larvæ into the host.**

References are given to literature on the subject.

**The control of the olive fly and Prof. Lotrionte's experiments (*Abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 7, pp. 1836-1838).—A study made by G. Lotrionte of aromas or scents most attractive to the olive fly, the influence of colored light, etc. is here summarized.**

Glucose was found much more attractive than molasses. An olive grove about 1 kilometer from other olive groves and sprayed 4 or 5 times with a mixture of glucose diluted with 20 per cent of water and 2 per cent of copper sulphate, was scarcely infected (0.33 per cent) whereas groves which had not been thus treated were infected to an extent of from 9 to 23 per cent. All olive trees treated with this mixture were in excellent condition, and free from sooty mold and from attack by *Cycloconium*.

**Numbers and types of bacteria carried by city flies, J. C. TORREY (*Jour. Infect. Diseases*, 10 (1912), No. 2, pp. 166-177).—“Flies examined up to the latter part of June were free from fecal bacteria and carried a homogeneous flora of coccal forms. During July and August there occurred periods in which the flies examined carried several millions of bacteria, alternating with periods in which the number of bacteria were reduced to hundreds. The scanty flora probably indicated the advent of swarms of recently hatched flies. Fecal bacteria of the colon type were first encountered in abundance the early part of July. The bacteria in the intestines of the fly were 8.6 times as numerous as on the surface of the insects. On the surface of the flies the colon group bacteria constituted 13.1 per cent of the total; and within the intestine 37.5 per cent of the total.**

“Of the lactose fermenters, isolated and identified, 79.5 per cent belonged in the colon-aerogenes group and 20.5 per cent in the acidilactici group. Fifteen cultures of streptococci, isolated and identified, were distributed among the equinus, fecalis, and salivarius groups. There were none of the pyogenes type. The most important isolations were 3 cultures of *B. paratyphosus*, Type A.

“Bacteria of the paracolony type causing a final intense alkaline reaction in litmus milk and fermenting only certain monosaccharids were frequently encountered during August.”

**Contribution to the knowledge of the biology of European rat fleas (*Ceratophyllus fasciatus*), N. H. SWELLENGREBEL (*Arch. Schiffs u. Tropen Hyg.*, 16 (1912), No. 6, pp. 169-182, figs. 4).—The author's studies are presented under the following headings: Distribution of fleas in the docks and other parts of Amsterdam, feeding experiments with the blood of man and the rat, longevity of unfed fleas, destruction of fleas, and personal prophylaxis.**

**Discussion on the spread of plague.** C. J. MARTIN (*Brit. Med. Jour.*, 1911, No. 2654, pp. 1249-1261, figs. 7).—Accounts are given of the transmission of plague by fleas, including a report of cage experiments; experiments in specially constructed brick animal houses from which fleas could be practically excluded; the fate of the plague bacillus in the body of the rat flea, and the mechanism by means of which the flea infects a healthy animal; the approximate proportion of fleas in the stomachs wherein multiplication of bacilli takes place; and similar topics.

**An attack of *Hylesinus piniperda* and *H. minor* in upper Dalarna, Sweden.** T. LAGERBERG (*Skogsvårdsför. Tidskr.*, 1911 *Åttmånna Delen*, No. 11, pp. 381-395, figs. 7).—An illustrated account of the injury caused by these scolytids, including a bibliography of 12 titles.

**The southern pine beetle and its control.** W. E. HUNDS (*Alabama Col. Sta. Circ.* 15, pp. 43-58, figs. 4).—This circular embodies most of the information relating to *Dendroctonus frontalis* given in Farmers' Bulletin 476 (E. S. R., 26, p. 476), together with other data. This pest is causing the death of pine trees of various species in increasing numbers, in Alabama.

**The movement of the Mexican cotton boll weevil in 1911.** W. D. HUNTER (*U. S. Dept. Agr., Bur. Ent. Circ.* 146, pp. 4, fig. 1).—During the season of 1911 the boll weevil was greatly reduced in numbers throughout its entire range, as the result of a combination of climatic influences extending over a period of about 3 years. So unfavorable were the conditions that the insect was exterminated in an area covering about 23,000 square miles in the northwestern portion of Texas and the western portion of Oklahoma.

Notwithstanding this great reduction in 1911, considerable advance was made to the East and North when the dispersion movement began in August. As a result of this extensive dispersion much of the territory it had lost in Texas and Oklahoma was regained, and Florida became invaded for the first time.

A map is given which shows the dispersion of the cotton boll weevil from 1892 to 1911.

**The insect enemies of the cotton boll weevil.** W. D. PIERCE, R. A. CUSHMAN, and C. E. HOOD (*U. S. Dept. Agr., Bur. Ent. Bul.* 109, pp. 99, pls. 3, figs. 26).—The authors' investigations are here presented in 3 parts, part 1 (pp. 12-39) dealing with the status of the cotton boll weevil and its enemies; part 2 (pp. 39-83) with the biological complex; and part 3 (pp. 83-96) with the economic application. A bibliography of 54 titles is appended.

The authors consider the control of the boll weevil by insect enemies to be sufficiently great to give it a high rank in the struggle against the pest. "A considerable portion of the insect control would not be accomplished by any other factor; hence it is by no means to be neglected. The number of species of insects attacking the developing stages is 49. The control in any given place consists of the combined work of several different species. Places having the largest number of controlling insects have the highest percentage of control. In many places insect control is considerably greater than climatic control or than any other class of factors. The average insect control is 20 per cent of all immature stages or two-fifths of the entire natural control.

"The cotton leaf-worm is a valuable enemy of the boll weevil when it defoliates the cotton after September 1, a date beyond which new squares can not be expected to mature. It kills many weevils by starvation, kills many others while consuming the squares, and finally forces a premature hibernation which is generally fatal.

"The amount of control due to the various factors at work in any given place should be increased if possible. Parasites can be introduced into new

fields. In order to prevent serious injury to cotton, the mortality of the weevil should be above 90 per cent. It has averaged over 57 per cent for 4 years and has reached almost 100 per cent several times. While climatic influences occasionally bring the control above 90 per cent, they can not be regulated or in any way directly utilized. . . .

"The parasites and predators which attack the boll weevil are native insects, already present in a given territory before the weevil arrives. . . . The weeds surrounding the cotton fields contain many weevils which are harboring multitudes of available parasites. These parasites may be induced to attack the boll weevil by the timely elimination of their native hosts. This leads to the recommendation that planters cut the weeds adjoining the cotton fields, along the roadsides, turn rows, and fences about the time of the maturing of the crop. It also leads to the recommendation that a field adjoining the cotton be used as a pasture or hay field, and that this field be mowed early in the fall. The usual haying will also bring about the same result—namely, the elimination of other plants harboring weevils which attract the parasites needed in the cotton patch. . . .

"The cultural methods of controlling the cotton boll weevil are the most favorable methods of cotton culture from the parasitic standpoint. . . . The fact that many more parasites are reared in hanging squares than in fallen squares makes it desirable in humid regions to have many of the hanging squares in a field in order to serve as a nursery of parasites for the weevils in and fallen squares. . . .

"Any step which will diminish the number of weevils and not diminish the number of parasites in a field will of course increase the percentage of parasites present. The most important step of this kind is the collection of infested squares and placing them in cages with a screen through which the weevils can not escape but the parasites can. Ant colonies may be introduced into the fields in boxes of fresh manure."

A weevil (*Æsotes leucurus*) destructive to pine trees (*Pinus halepensis*), W. W. FROGGATT (*Agr. Gaz. N. S. Wales, 23 (1912), No. 1, pp. 55, 56, pl. 1*).—It is stated that this weevil is destroying every pine tree in an avenue in the neighborhood of Strathfield.

Historical notes on the causes of bee diseases, E. F. PHILLIPS and G. F. WHITE (*U. S. Dept. Agr., Bur. Ent. Bul. 98, pp. 96*).—This bulletin reviews papers relating to the etiology of bee diseases, in chronological order. The purpose of the bulletin is to assist bee keepers in obtaining a proper understanding of the work done by the various investigators.

Descriptions of two new genera and six new species of parasitic Hymenoptera, A. B. GAHAN (*Proc. Ent. Soc. Wash., 14 (1912), No. 1, pp. 2-8*).—The new species here described include *Allorhogas gallicola* n. g. and n. sp., reared from cynipid twig galls on *Quercus pinifolia* from which the moth *Synanthedon scitula* was reared and on which it is thought to be parasitic; *Synaldis incisa* n. sp., taken from cages in which the Hessian fly was being reared and on which it is possibly parasitic; *Ditropinotus flavicornis* n. sp., taken from a room in which quantities of insect-infested meal and other ground feed was stored; *Agromyzaphagus detrimentosus* n. g. and n. sp., reared from the puparia of an agromyzid fly, probably *Leucopis nigricornis*; and *Hoplogryon kansasensis* n. sp., taken from a cage in which experiments with the Hessian fly were being carried on.

The cotton leaf blister mite in Barbados (*Agr. News [Barbados], 11 (1912), Nos. 258, p. 90; 259, p. 106*).—It is stated that *Eriophyes gossypii*, first discovered in Barbados on February 27, 1912, infests an area which includes a strip some 2 or 3 miles wide along the westward coast for a distance of 18

miles, the southern limit apparently being about 4 miles southeast of Bridgetown. A committee has been appointed by the government of the island to investigate and report upon the steps that should be taken to stamp out the pest.

**Insecticides:** Mixtures and recipes for use against insects in the field, the orchard, the garden, and the house, H. MAXWELL-LEFROY (*Agr. Research Inst. Pusa [India] Bul. 23, 1911, pp. 22, pls. 11*).—A popular account including illustrations of spraying apparatus and of the author's mosquito trap.

## FOODS—HUMAN NUTRITION.

The bacteriology of eggs and egg products with special reference to *Bacillus coli*, O. MAURER (*Kansas Sta. Bul. 189, pp. 333-344*).—Eggs were examined for the presence of *B. coli*, the work being undertaken as a part of a study of the economic aspects of the egg industry and particularly with reference to the deterioration of frozen and desiccated eggs.

Sixty fresh clean eggs from 30 different hens, the eggs being collected twice a day from trap nests, 50 eggs obtained from local farms, and 25 dirty eggs obtained from a packing house were used. "These [dirty] eggs were at least 3 weeks old, and were fairly covered with droppings." The colon bacilli were absent from the contents of all the eggs studied and from the shells of about 77 per cent of the clean eggs, and from 82 per cent of the farm eggs, but were found on the shells of all of the dirty eggs.

Experiments were made under a variety of conditions, including low temperature, with eggs smeared with feces (fecal bacteria) and egg and with a suspension of *B. prodigiosus*. In general, the results indicated that the microorganisms under consideration did not penetrate the unbroken shells of the eggs.

Experiments also showed that concentrated egg albumin did not exercise any bactericidal action upon *B. coli*, a result in harmony with that of other investigators. "Indeed, the presence of large numbers of colon bacilli in frozen and desiccated eggs would be impossible if the egg possessed bactericidal properties for this organism.

"It seems, therefore, that the only explanation we can give for the absence of *B. coli* from fresh eggs and from the oviduct is the lymphoid structure of the mucosa of the oviduct. This probably causes the removal, by leucocytic activity, of colon bacilli which have reached the oviduct, together with other intestinal organisms."

In general, the author concludes that fecal matter, which owing to the way they are handled comes in contact with the egg contents when they are broken and the yolk and white separated, is the source of the large number of colon bacilli often present in egg preparations.

"The bacterial content of canned eggs may be greatly reduced by separating only clean eggs. All soiled eggs which either directly or indirectly might give rise to fecal contamination of the egg meat should be utilized without separating the white from the yolk.

"[In preparing such egg products] the girls who break the eggs should wash their hands whenever they come in contact with the contents of bad eggs or with other contaminating material. The wash water should be used only once; indeed, a pail with water in which the girls frequently wash their hands makes matters worse. The cups into which the eggs are broken, and all other utensils that come in contact with the egg meat, should be washed in clean water whenever touched by contaminating material. These should not have any crevices, corners, etc., where material may accumulate, but should be as

smooth as possible. Glass cups are best. Live steam should be applied liberally to sterilize utensils, etc.

"The room in which the eggs are broken should be as cool as it can possibly be kept without making the inmates uncomfortable. The cleaner the room and everything in it, the fewer bacteria the product prepared in it will contain. The egg meat should be transferred to the freezing room as soon as possible."

A discussion of the healthfulness of frozen and desiccated eggs and of the need and value of bacteriological methods of judging them, O. MAURER (*Kansas Sta. Bul. 180, pp. 345-359*).—In connection with a summary of data regarding the bacterial contamination of egg products, experiments were made on the effects of heating such eggs for varying periods of time to 65, 70, and 75° C. in a water-jacketed oven.

When samples were heated to 75° the solubility of the goods was rapidly decreased.

With regard to wholesomeness, the author concludes that "in the absence of physical signs of decomposition, there is no danger of poisonings or bacterial infections through egg products.

"Bacteriological methods for judging the healthfulness of egg preparations are unnecessary and inapplicable.

"The sanitary conditions under which frozen and desiccated eggs are produced can not be judged by our present bacteriological methods, because the bacterial content of egg preparations is subject to great seasonal and local variations.

"Factory inspection should enforce sanitary methods of production and should exclude from the frozen and desiccated products all eggs that are not admitted to the market in the shell. . . .

"The bacterial content of desiccated eggs can, by keeping them for from 1 to 2 hours at 65 to 70°, be greatly reduced without decreasing their solubility very much. Practical tests will have to decide whether the advantages derived from the lower bacterial content would counterbalance the disadvantages arising from the somewhat lower solubility."

Besides desiccated eggs designed for food similar goods are made for trade purposes.

"In the manufacture of tanners' eggs, the sound portion of spot-eggs, eggs showing blood rings, and slightly off-flavored eggs are used. After desiccation, this product can hardly be distinguished, by its physical appearance, from first-grade eggs. When one sees and tastes this product, it seems a needless waste that it should be excluded from human consumption. Perhaps future researches will show us that a good many eggs which are now prepared for tanners are perfectly healthful and fit for human consumption. . . .

"All eggs that are really unfit for food, however, should be denaturized, to prevent unscrupulous people from selling them for food purposes. . . . After such eggs are sold to the tanners, it is very hard to keep track of them, and they may in a roundabout way make their appearance in cheap restaurants, etc. Denaturization of such preparations is the only sure way to prevent their use as food products. It would easily be possible to find a substance which, when added to tanners' eggs, would serve as a telltale without exerting a deleterious effect upon the leather."

Proper handling of dressed poultry, MARY E. PENNINGTON (*Butcher's Advocate, 52 (1912), No. 22, pp. 11, 12, dgms. 4*).—This article includes a description of the refrigerating plant used in connection with the work of the U. S. Department of Agriculture (*E. S. R., 25, p. 579*) in a laboratory devoted to the problem of handling poultry, a description of the temperature variations in

refrigerator cars, methods of packing and shipping poultry, and the changes likely to affect the birds during transportation.

**Bacterial purification of oysters by floating in filtered artificial sea water**, FABRE-DOMERGUE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 6, pp. 393-395).—A description of tanks for floating oysters. Artificial sea water is passed through the tanks in which the oysters are placed, pumped through a filter, and again passed into the tanks. In the opinion of the author the results are practically the same as those with natural sea water.

**Floating oysters in filtered artificial sea water**, E. BODIN (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 7, pp. 446, 447).—An account of tests made with oysters floated in tanks similar to those described in the above article.

Oysters may be floated in such tanks for a month without losing their vitality or good appearance. Slight changes in flavor may take place after one week. As a method of bacterial purification, the method is considered as satisfactory as floating in natural sea water.

**Cheese and its economical uses in the diet**, C. F. LANGWORTHY and CAROLINE L. HUNT (*U. S. Dept. Agr., Farmers' Bul.*, 487, pp. 40).—This popular summary includes data regarding cheese making, the care of cheese in the home, and the flavor of cheese, describes the kinds of cheese used in American homes, and discusses the food value of cheese, its composition, nutritive value and cost as compared with other foods, its digestibility, its use in the diet, and the making of bills of fare with cheese as the central food.

Directions are given for preparing homemade cheeses and a large number of cheese dishes of different sorts, which have been studied experimentally.

The widespread belief that cheese is not thoroughly digested and that it is often a cause of physiological disturbance is not substantiated by the experimental data summarized in this bulletin.

As a whole, the bulletin calls attention to the high nutritive value of cheese and the possibility of using it in many ways.

**Kafir corn flour bread**, C. DILLON (*Northwest. Miller*, 90 (1912), No. 2, pp. 79, 80, figs. 4).—A description of baking tests made by students of the Kansas Agricultural College in 1911. Various recipes for breads, cakes, etc., were studied experimentally, white durra flour, black-hull Kafir flour, white durra meal, and black-hull Kafir meal being tested.

The only difference noted between the white and the black-hull flours, or the corresponding meals, was the darker color of the black-hull products. In bread making it was found that these meals and white flour 1:1, 1:2, or 2:1 all made fairly satisfactory loaves, though a mixture containing the highest proportions of white flour made the lightest bread.

"The meal makes a good substitute for corn meal, as it can be used in practically every case that corn meal is used. When the meal is used alone, more liquid is required to mix it, and it lacks sufficient gluten to hold together. It also is rather harsh and flat tasting when used by itself, but when mixed with wheat flour the flavor is pleasant. The wheat flour also supplies the gluten, which makes its use much more successful. In most cases a mixture of two of meal to one of flour is good and in nearly all cases a mixture of 'half and half' is successful."

**Coffee and coffee substitutes** (*Quart. Bul. Bd. Health N. H.*, 1 (1912), No. 1-2, p. 3).—Analyses are reported of various coffee mixtures and coffee substitutes.

"Incidentally it is of interest to note the difference between the now well-known non-coffee containing coffee substitutes and the newer coffee-cereal mixtures, in that, whereas the former consist mainly or wholly of bran, worth in most cases not over 3 or 4 cts. a pound at the most, the cereal or leguminous

portion of the latter is apt to represent the whole berry, rather than mere refuse."

Food analyses No. XXXVII, H. P. CADY and JACKSON (*Bul. Kans. Bd. Health*, 8 (1912), No. 3, pp. 53-63).—Analyses of miscellaneous food materials are reported.

[Food inspection and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1912), No. 1, pp. 16, fig. 1).—Chemical preservatives, coal-tar dyes, and other questions are considered and data reported regarding the examination of miscellaneous food products.

A paper by R. E. Remington on the protein content of vinegar gives analyses of vinegars, malt vinegars, and sugar vinegar, and a determination of protein in fresh juice expressed from Jonathan apples. The filtered apple juice, preserved for several weeks, yielded 0.007 per cent nitrogen, corresponding to 0.64 per cent protein. The analytical data are discussed with reference to vinegar standards.

If further work should confirm the authors' report, "and the protein content in nonsugar solids in cider vinegar be found to lie within comparatively narrow limits, i. e., 0.8 per cent to 1.5 per cent, this determination will furnish a simple means of detecting adulteration of cider vinegar with grain or molasses vinegar, on the one hand by high protein content, and with distilled vinegar on the other by low protein content."

L. A. Congdon reports a study of the coating and polishing of rice. His conclusions follow:

"The principal reason that rice is coated is for covering up poorer grade and quality.

"Rice is said to be prepared commercially by a polishing process, in which glucose, 1/1,000, and talc, 1/3,000 part of the whole, are added. Paraffin and rice starch are sometimes used in place of glucose and talc.

"Rice may be said to be coated with talc, glucose, and rice starch if the percentage of solids in the washings of the rice is above 1 per cent, and the percentage of ash in washings is above 1/10 of a per cent.

"Rice may be said to be coated with glucose and rice starch if the percentage of solids in the washings of the rice is above 1 per cent, and the percentage of ash in the washings is below 1/10 of a per cent.

"Rice may be said to be uncoated or not polished to any degree if the percentage of solids is below 1 per cent in the washings, and the percentage of ash in the washings is below 1/10 of a per cent; provided the rice has been tested for a coating of paraffin. Paraffin was found in 1 sample to the amount of 0.260 per cent."

[Food inspection and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 1 (1911), No. 39, pp. 453-468, figs. 2).—Results of the examination of a number of samples of miscellaneous food products, beverages, and sugar beets are reported, and various food topics discussed.

Twenty-sixth annual report of the Ohio Dairy and Food Commissioner, S. E. STRODE (*Ann. Rpt. Ohio Dairy and Food Comr.*, 26 (1911), pp. 117, pls. 3).—A report of legislation, recommendations, prosecutions, inspections, analyses of miscellaneous food products, and similar data.

[A summary of the work of the food and dairy commission for the year ending June 30, 1911] (*Ann. Rpt. Food and Dairy Comr. S. Dak.*, 11 (1911), pp. 117).—Inspections, prosecutions, and analyses made are reported and a summary of the publications of the commission included.

**Laws of Massachusetts pertaining to the business of slaughtering** (*Boston: State Bd. Health, 1911, pp. 12*).—A summary of the laws regulating slaughtering in Massachusetts, with special reference to the changes required by the acts of 1911.

**The progress of international commerce in perishable foodstuffs, II. HITLER** (*Ann. Géogr., 21 (1912), No. 116, pp. 109-117*).—A summary of the development of commerce in perishable goods, with special reference to conditions on the continent of Europe.

**Gas and electric cooking** (*Jour. Gas Lighting, 118 (1912), No. 2551, pp. 17, 18*).—An account of tests made in England.

The initial cost of an electric cooker and installation is reckoned as 75 per cent more than that of a gas cooker. Comparative tests were made of the cost of boiling water and baking sirloin of beef, cakes, etc. In all cases the cost of fuel was found to be greater with the electric cooker than with gas. In the sirloin of beef the loss by evaporation was 13 per cent with the electric, and 16 per cent with the gas, cooker. In boiling 1 qt. water it was found that the electric cooker required 12 minutes longer than the gas ring, and that the electricity required cost 0.5 ct. more than the gas.

**A gas cooker of novel construction** (*Jour. Gas Lighting, 117 (1912), No. 2550, pp. 870, 871, figs. 4*).—The oven here described is built with 2 metal walls with an air space between, the gas heating the air in the latter. It is claimed that as there is no gas burning in the oven spurting fat will not come in contact with the flames and cause a disagreeable smell, and that since the oven is enclosed the loss through evaporation during cooking will be less than in the ordinary oven. Temperature and cooking tests are given which, according to the author, indicate the economy of a cooker of this description.

**The conditions of nourishment of pupils in Munich public schools, K. OPPENHEIMER and W. LANDAUER** (*München. Med. Wochenschr., 58 (1911), No. 42, pp. 2218-2220; 59 (1912), No. 13, pp. 795, 796, dgm. 1*).—The first of these articles reports a study of the physical condition of school children in 2 public schools in Munich, one in a district populated mainly by day laborers, and the other in a district including some families in more easy circumstances. Age, general condition, weight, height, chest, and upper arm measurements were noted, and the relation between height and body weight of each child was calculated. Comparing the figures thus obtained with those commonly accepted as standard for children of various ages, the authors found that the children in both the schools investigated, but notably in that in the poorer section of the city, were on the average decidedly below normal.

The second article is an answer to criticisms called out by the deductions that the children here studied were necessarily undernourished. The authors suggest the distinction between quantitative and qualitative undernourishment and discuss the most satisfactory means of determining general physical development from physical measurements and similar topics.

**Second experimental march to investigate the amount of food required by men on active service** (*Jour. Roy. Army Med. Corps, 17 (1911), No. 6, pp. 629-643*).—The march here reported was made in August, 1910. It lasted 13 days, included men and officers, and was in every way comparable with the previous march (E. S. R., 25, p. 266). The men returned to the same camp each night. Physical measurements were taken every morning under conditions as nearly uniform as possible. The weather conditions were hardly better than during the first march, while the character of the roads was worse.

The ration was varied somewhat from that of the first march, bacon and cheese being substituted for part of the meat in different quantities during dif-

ferent periods of the march. The ration of jam was increased and pickles were added, but this latter addition was not appreciated by the men. The total ration provided 142 gm. of protein per man per day during the first week, and 175 gm. during the second week of the march. The average energy supplied was 4,511 calories per man per day. The total muscular work, external and internal, was calculated as 3,989 calories per man per day, an amount practically identical with that noted during the previous march.

The weight curves show an average gain during the first few days, next a slight fall, followed by a second gain, and a second smaller fall. Instead of an average loss such as appeared during the previous year, there was an average gain of 0.16 kg. in the weight of the men at the end of the march. They showed no symptoms of underfeeding, as in the previous case, and considered their diet in every way adequate.

In the opinion of the committee, a ration furnishing 4,500 calories of energy per man per day, and containing a larger proportion of fat and sugar than that found in the present ration, should be adopted by the British Army.

It is stated that the nitrogen balance of 2 of the officers during the second experimental march will be published later.

**The disappearance of beri-beri from the Philippine (native) scouts, W. P. CHAMBERLAIN** (*Military Surg.*, 28 (1911), No. 5, pp. 509-522).—During the year 1910 changes were made in the rations for Philippine scouts which slightly preceded the change which was effected in the general Philippine ration. This preliminary change did not substitute unpolished for polished rice, but reduced the amount of polished rice, substituting for it legumes, ginger root, and various native vegetables. Aside from the change in the diet, conditions among the Philippine scouts remained practically the same as those in other native troops.

The health sheet of the scouts showed no remarkable changes except the disappearance of beri-beri. The Board for the Study of Tropical Diseases as They Exist in the Philippine Islands, which suggested the change, believes that the disappearance of the disease is due to the substitution of other vegetables for part of the polished rice. It does not hold that this contradicts the polished rice theory of beri-beri, but rather that it supports it, the substitution of vegetables for part of the polished rice in its opinion furnishing necessary mineral matters lacking in the polished rice.

**Report of the U. S. Army Board for the Study of Tropical Diseases as They Exist in the Philippine Islands, W. P. CHAMBERLAIN, H. D. BLOOMBERGH, and E. B. VEDDER** (*Military Surg.*, 28 (1911), No. 4, pp. 445-452).—Data are summarized regarding the disappearance of beri-beri from the native Philippine scouts which followed a change in ration. The preparation of rice of different sorts is discussed and some data presented regarding the experimental work with poultry on rice in relation to the development of polyneuritis.

**The influence of fat in the food upon the body fat of carp, J. KÖNIG, A. THIENEMANN, and R. LIMPRICH** (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 5, pp. 177-197).—Among the conclusions drawn as the result of these investigations were that feeds with a high fat content produced a high fat content in the flesh of fish. Phytosterin was not detected in the body fat. The nature of the food fat or its cleavage products affected the taste of the fish, and in certain cases it became unpalatable. Analyses of the experimental animals and of several other species of fish are reported.

**The condition of the liver as influenced by various kinds of food fats, S. S. CHALATOW** (*Arch. Path. Anat. u. Physiol. [Virchow]*, 207 (1912), No. 3, pp. 452-469).—The author fed rabbits and white rats on diets consisting in different instances of sunflower seed oil, beef tallow, liver fat, ox brain, and

egg yolk, the experiment being continued for periods of several months each.

The most common phenomena which occurred in all of the experiments was that in the first period after the beginning of the feeding the liver of the animals became filled with greater or less quantities of fatty substances. With continued feeding of the same materials the fat masses in the liver not only did not increase, but, on the contrary, became gradually smaller and finally disappeared entirely.

The various fats did not produce the same effects in the animals. Whereas, according to the author, the liver disposed of sunflower seed oil, liver fat, and beef tallow with considerable ease, and feeding these substances produced no serious changes in the liver, feeding with egg yolk and ox brain brought about, in all cases, noticeable and generally similar pathological changes in the liver, which increased as the feeding periods lengthened. From this it may be concluded that these changes were not conditioned by the fats, but rather by the lipid substances (probably those of the lecithin group) which in such cases were filtrated into the liver cells, together with the neutral fat, and frequently surpassed the latter in amount.

The effect of the different fats was not the same on rabbits as on rats. This difference in the behavior of the 2 species as regards the lipid substances can, the author believes, be attributed to the fact that certain anatomical peculiarities of the rabbits produced certain not yet understood fermentations under the influence of which toxic modifications are produced out of the lipid substances. In general, the changes produced when rats were fed with egg yolk were similar to those taking place in rabbits fed with sunflower oil, liver fat, and beef tallow.

**Lecithin and its significance.** J. NERKING (*Internat. Beitr. Path. u. Ther. Ernährungsstör. Stoffw. u. Verdauungskrank.*, 3 (1912), No. 4, pp. 455-461).—This article is a summary of the theories regarding the rôle of lecithin in nutrition and its therapeutic use. The author concludes that for the latter chemically pure lecithin is necessary, but that most of the preparations commercially obtainable are of this character.

**The respiration calorimeter—application to the study of problems of vegetable physiology.** C. F. LANGWORTHY and R. D. MILNER (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 116, pp. 3).—A brief description is given of the large calorimeter used for experiments with man and of a new respiration calorimeter of smaller size suitable for experiments with fruits and similar products which has recently been installed. Reference is also made to a micro-calorimeter for use in the experimental study of very small quantities.

Recording and controlling devices of special construction involving much that is new and original have been used in the construction of the respiration calorimeter designed for the study of vegetable problems, so that the instrument will be very largely automatic in operation and can be operated at the same time and by the same observers as are employed upon experiments with man in the large calorimeter.

The work which has been done thus far with ripening fruit has demonstrated that the respiration calorimeter is fully as well suited to the study of certain fundamental problems of plant life as to the study of similar problems of animal life.

The apparatus can also be used, it seems safe to conclude, in studying such problems as the changes which take place when meat or cheese or other similar products are cured or ripened, and factors which influence these changes; that is, problems which are of commercial interest as well as of agricultural, domestic, and scientific importance.

## ANIMAL PRODUCTION.

[Nutrition investigations], H. L. RUSSELL (*Wisconsin Sta. Bul.* 218, pp. 4-10, figs. 4).—A brief report of work in progress at the station on the efficiency of rations from single plant sources, studies in protein nutrition, mineral requirements of farm animals, grain mixtures for feeding show sheep, and soilage versus silage for dairy cows.

Analyses of fodder plants, grasses, ensilages, etc., J. C. BRÜNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1910-11, pp. 56, 57).—Analyses are reported of white panicum (*Panicum frumentaceum*), common panicum (*P. germanicum*), *P. bulbosum*, summer grass (*P. sanguinale*), Japanese millet, blady grass (*Imperata arundinacea*), blue grass (*Andropogon sericeus*), scented blue grass, 3 varieties of *Vigna catjang* (mammoth, purple and black cowpea), tall oat grass (*Anthistiria arvenacea*), American grass (*Tripsacum dactyloides*), lab lab bean (*Dolichos lab lab*), sorghum, native vetch, red Natal grass (*Tricholana leucrifia*), lucern, and *Lotus australis*.

The use of ensilage (*Bul. Off. Gouv. Gén. Algérie*, 1911, No. 15, Sup., pp. 251-315, figs. 14).—This discusses the different types of silos, and methods of growing silage crops and feeding silage, with special reference to Algerian conditions.

The large sunflower and sunflower cake, J. H. PAPAIOANNOU (*Ann. Gemblour*, 22 (1912), Nos. 2, pp. 74-101; 4, pp. 209-234, pls. 2).—A review of experiments relating to growing and utilizing the sunflower and its by-products as a feeding stuff, including the methods of growing the plant and feeding it. Analyses of the stem, leaves, head, seed, and cake, and samples of rations containing sunflower cake are given.

[Analyses of feeding stuffs], A. P. SANDLES (*Ann. Rpt. Ohio Bd. Agr.*, 65 (1910), pp. 441-512).—This is the official report of feeding-stuff inspection during the year 1910. The analyses reported include cotton-seed meal, linseed meal, gluten feed, malt sprouts, hominy feed, distillers' and brewers' dried grains, tankage, beef scrap, and proprietary mixed feeds.

Stock feed: Bran, shorts, chop feed, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 231, 1912, pp. 41).—Analyses are reported of bran, shorts, middlings, and mixed feeds.

Investigations on the stomach of ruminants, especially the Tragulidæ, E. SCHMIDT (*Arch. Naturgesch.*, 77 (1911), I, No. 2, pp. 1-40).—A study of the comparative anatomy of the stomach of ruminants. Those of the species examined appeared to be on the same general plan. *Hyemoschus* having the simplest and cattle the most complex type. The S-form of paunch in the embryonic calf is very similar to that of the mature paunch of the Tragulidæ.

A bibliography is appended.

The effect of alcohol on the movements of the paunch in ruminants, O. KNAUPP (*Klinische und Experimentelle Studien über die Wirkung des Spiritus auf die Mägen der Wiederkäuer. Inaug. Diss., Univ. Giessen*, 1911, pp. 76, pl. 1, figs. 19).—The frequency of the paunch movements in cattle, sheep, and goats was found to be dependent upon the nature of the food. The frequency and intensity was increased immediately after eating or after the administration of alcohol.

The significance of the pulse rate in vertebrate animals, FLORENCE BUCHANAN (*Ann. Rpt. Smithsn. Inst.*, 1910, pp. 487-505, figs. 3).—The heart weight, pulse rate, and oxygen supply of wild and domesticated birds and mammals are given. The method of taking the pulse rate of small birds and mammals by means of a capillary electrometer is described, and the value of collecting such data is pointed out.

There was found to be a relatively larger heart in the more active animals, which means better staying power, as the longer diastole gives more time for recuperation. Small hearts and quick pulses are more characteristic of domesticated animals than of wild animals, except the race horse, as the most active individuals, because of their unruly nature, are often discarded for breeding purposes.

**Contribution to the knowledge of the temperature of the skin of horses and cattle.** R. SPOERL (*Beiträge zur Kenntnis der Hautwärme bei Pferd und Rind. Inaug. Diss., Univ. Giessen, 1911, pp. 49*).—Temperatures taken in different parts of the body under different conditions are presented in tabular form.

In all cases the temperature of the skin was lower than the rectal temperature, and in all parts of the body was lower in cattle than in horses. The highest temperature was along the median line of the udder in cows, and near the heart and on the throat in horses. The lowest temperatures were at the extremities of the limbs.

**Rôle of interstitial testicular cells,** L. MAZZETTI (*Anat. Anz., 38 (1911), No. 14-15, pp. 361-387, figs. 14; abs. in Jour. Roy. Microsc. Soc. [London], 1911, No. 6, p. 740*).—Interstitial cells from the frog, bird, dog, and man were found to be transformations of connective cells which proliferate between the tubules. They may also arise from lymphatic lacunæ. It is thought that they are of either no importance or possibly of some slight significance in connection with secondary sexual characters.

**Biometric ideas and methods in biology; their significance and limitations,** R. PEARL (*Scientia, 10 (1911), pp. 101-119; abs. in Zentbl. Allg. u. Expt. Biol., 2 (1912), No. 21-23, p. 576*).—The author sketches the rise and progress of biometry as a method of research in anthropology and biology, and shows that the real purpose of biology is quantitative treatment and does not imply any particular theory of heredity or variation. Its particular use lies in the fact that it solves the problem of describing the group in terms of its attributes and qualities, and not of individuals. Some of the limitations of the method and the errors that may arise in the improper use of biometric methods are pointed out.

**Skull measurements in man and the hoofed mammals,** H. F. OSBORN (*Science, n. ser., 35 (1912), No. 902, p. 596*).—The cephalic indexes and limb ratios are considered by the author to have the value of specific characters and, therefore, to be more significant than direct measurements in the study of comparative anatomy of hoofed animals. For example, in a cross between the horse and ass the cephalic indexes are found to be pure nonblending characters. Among the most significant indexes are the cephalic, the cranial, and the facial.

**Breeding in the State of São Paulo, Brazil,** L. MISSON (*L'Élevage dans L'État de São Paulo (Brésil). Gort. [1910?], pp. 90, figs. 58*).—A general statistical article, with special reference to pure-bred live stock.

**Stock breeding in Kafa, Abyssinia,** BIEBER (*Deut. Rundschau Geogr., 1911, No. 7; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 6, p. 1402*).—An outline of the live-stock situation.

The principal kinds of animals kept are zebu, fat-tailed sheep, horses, mules, and goats. The fowls are small and lay but few eggs, which are not eaten by the natives. Live stock methods are very primitive. Oxen are used only for plowing, horses for riding, and asses and mules as pack beasts. Milk is used chiefly for butter making. All kinds of live stock are cheap. Civets are also bred on a large scale, but only males are reared to any extent, as the females do not yield the product used in perfumery and tobacco factories.

**The live-stock markets of London** (*Breeders' Gaz., 61 (1912), No. 16, pp. 937, 938, figs. 6*).—An account of the English methods of marketing live stock

as seen at Islington and Deptford, as contrasted with customs in American live-stock markets. In 1911, 50,324 cattle were received at Islington, as compared with 223,600 in 1887, and the number of sheep 330,745, as compared with 877,810 in 1893. At Deptford the number of cattle arriving in 1911 was 66,877, a decline of about 5,000 from the previous year. It is thought that there will be a still further decline in both markets.

**Reproduction and inheritance in race hygiene**, M. VON GRUBER and E. RÜDIN (*Fortpflanzung Vererbung Rassenhygiene. Munich, 1911, pp. 178, figs. 230*).—This contains photographs and detailed descriptions of the exhibits at the International Hygiene Exhibition held at Dresden, 1911, which illustrate reproduction, variability, selection, mutation, inheritance of acquired characters, laws of inheritance, Mendel's law, inheritance in man, degeneracy, race hygiene, and neomalthusianism.

A bibliography of about 1,000 titles on these topics is appended.

**The Bakker-Dettweiler theory of the ancestry of the black and white cattle**, H. LAESSIG (*Mitt. Deut. Landw. Gesell., 27 (1912), No. 2, pp. 21-24*).—The author believes that the conclusions of Bakker and Dettweiler (*E. S. R., 26, p. 166*), regarding the color of cattle at different times in the history of Holland are erroneous, because they are based largely on the colors of cattle in paintings. The Dutch painters were colorists, and consequently used color in many cases where it did not occur in nature.

**On the origin and classification of our domesticated cattle**, P. HOLDEFLEISS (*Illus. Landw. Ztg., 31 (1911), No. 86, pp. 805-807*).—The author thinks that the introduction of black cattle from Jutland to Holland took place much earlier than stated by Dettweiler (*E. S. R., 26, p. 166*). In the study of relationships, it is thought that too much emphasis has been laid upon osteological differences, whereas pigmentation and other physiological properties have been minimized.

**The origin and classification of our domesticated cattle**, G. LAURER (*Illus. Landw. Ztg., 31 (1911), No. 91, pp. 850, 851*).—The author points out that pigmentation is of little diagnostic value because the different breeds can not be separated into spotted and shaded types as Holdefleiss indicates in the article noted above. The question of geographical distribution of breeds is also discussed.

**The cattle of Friuli**, E. MASCHERONI (*Corriere Macelli, 2 (1911), No. 2, pp. 15-20; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases, 2 (1911), No. 6, pp. 1403, 1404*).—A general and statistical article on the cattle industry in Friuli. Since 1878 the cattle have been much improved by crossing the native draft stock with the Simmental. There are about 250 co-operative creameries in the province, and 70,000 calves are exported annually. The methods of fattening cattle are described.

**Returns at the Modena slaughterhouse**, G. SQUADRINI (*Corriere Macelli, 2 (1911), No. 3, p. 32; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases, 2 (1911), No. 6, pp. 1419, 1420*).—Data show that the Modena lowland breed of cattle is superior in net returns to the mountain breed, and also to other breeds slaughtered except the Bologna, Romagnole, and Friuli breeds.

**The exportation of cattle**, C. ROBLLS and A. V. HERNÁNDEZ (*Econ. Mexicano, 52 (1911), No. 19, pp. 361-365*).—This contains statistics on the exports of cattle and hides from Mexico. From 1903 to 1910, inclusive, 983,899 head of cattle and 84,692 tons of hides were exported.

**On the effects of castration and ovariectomy upon sheep**, F. H. A. MARSHALL (*Proc. Roy. Soc. [London], Ser. B, 85 (1912), No. B 576, pp. 27-32*).—This

article discusses the differences in the horn growth of the various British breeds, and reports experiments with the Herdwick breed.

"The development of horns in the males of a breed of sheep in which well marked secondary sexual differentiation occurs (as manifested especially by presence or absence of horns) depends upon a stimulus arising in the testes, and this stimulus is essential, not merely for the initiation of the horn growth but for its continuance, the horns ceasing to grow whenever the testes are removed.

"The removal of the ovaries from young ewes belonging to such a breed does not lead to the development of definitely male characters, except possibly in an extremely minor degree."

**The native sheep of Manche.** G. GAUDOT (*Jour. Agr. Prat., n. ser., 23 (1912), No. 10, pp. 398, 399, pl. 1*).—The characteristics of the sheep in the department of Manche, and in particular the native breeds found in the region along the shores of the English Channel, are described.

**The sheep of the Roman fields.** B. BIANCHINI (*Gior. R. Soc. Naz. Vet., 59 (1910), Nos. 51, pp. 1218-1223; 52, pp. 1252-1256; 53, pp. 1265-1269; 60 (1911), Nos. 5, pp. 108-112; 6, pp. 123-127; 7, pp. 145-148; 8, pp. 175-179*).—A description of the types of sheep, both native and introduced, with a view to their improvement by better breeding and management.

**Grazing farms.** W. G. BROWN (*Queensland Agr. Jour., 28 (1912), No. 2, pp. 98-101*).—Estimates are given of expenditures and returns on a 20000-acre sheep ranch in Queensland.

**Iceland wool.** A. E. INGRAM (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 82, p. 89*).—This gives the amount and value of exports of Iceland wool to the United States and Great Britain, and recommendations for preparing and grading wool for export.

**Algerian wool.** (*Bul. Off. Gourt. Gén. Algérie, 1911, No. 14, Sup., pp. 207-247; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 7, pp. 1725, 1726*).—Statistical data on the wool production in Algeria since 1870 are reported.

**A few observations on birth of goats.** ALBRECHT (*München. Tierärztl. Wehnschr., 55 (1911), Nos. 29, pp. 481-485; 30, pp. 501-506*).—These articles report data on birth weight and after-birth weight, the relation of these weights to each other and to the weight of the mother, and the length of the parturition period.

**A cage for metabolism experiments on goats.** A. R. ROSE (*Biochem. Bul., 1 (1911), No. 2, pp. 222-226, pl. 1*).—This is a more detailed description of a contrivance previously noted (*E. S. R., 26, p. 268*).

**Breeds of pigs suited for breeding on a small scale.** SCHWARZ (*Arb. Landw. Kammer Pommern, 1911, No. 22, pp. 22; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 6, pp. 1410, 1411*).—This contains brief descriptions of breeds of pigs raised in Germany, with methods of feeding and breeding.

**Chinese pork for export.** R. S. GREENE ET AL. (*Daily Cons. and Trade Rpts. [U. S.], 15 (1912), No. 101, pp. 390-393*).—This consists of brief reports from several consulates.

The feeds commonly used to produce pork for export consist largely of by-products of the rice mills, soy-bean oil factories, breweries, and distilleries. The pork is stated to be of good quality and not more subject to disease than that produced elsewhere. Hankow is the center of the export trade in hogs, but it is stated that the finest pork comes from the province of Yunnan.

**Monographs on the Belgian draft horse, II. DE THEULEGOET** (*Monographie du Cheval de Trait Belge. Brussels, 1911, pp. 122, pls. 14*).—This contains the pedigrees and photographs of good types of Belgian draft horses. There is also a brief account of the origin of the domesticated horse, and particularly the origin of the breeds found in Belgium.

**Origin of the Percheron horse, G. POWELL** (*Farm and Ranch Rev., 7 (1911), Nos. 22, pp. 750-752; 23, pp. 792, 793*).—This is a translation of a chapter from a new book on the horse by G. Trolet.

**Some early importations of noted horses to this province, J. RICHARDS** (*Ann. Rpt. Dept. Agr. Prince Edward Island, 1911, pp. 79-87, fig. 1*).—These are notes on the importation of pure-bred horses to Prince Edward Island, begun with that of True Briton, a Suffolk Punch, imported in 1824.

**Horse breeding in the time of Frederick William II, P. MARTELL** (*Tierarzt. 51 (1912), No. 7, pp. 97-102*).—A historical note on horse breeding in Germany, with special reference to the efforts of Frederick William II to improve the character of horses used for military purposes.

**Horse breeding in South Africa, W. G. RATTRAY** (*Agr. Jour. Union So. Africa, 3 (1912), No. 2, pp. 205-218*).—This contains some historical notes on the character of the horses in South Africa. It is advocated that more attention be paid to the breeding of horses in the future.

**Kansas State Live Stock Registry Board: Report No. 2** (*Kansas Sta. Bul. 179, pp. 209-331, pls. 14*).—This contains portions of the text of the state law relating to the registration of stallions and a discussion of its benefits, fraudulent pedigrees, the status of the non-standard stallion, and similar topics. There are several popular articles on the breeding and management of horses written by different authors, and a list of stallions, licenses, and transfers for the year ended October 1, 1911.

**Origin of the domestic dog, E. L. TROUESSART** (*Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 909-913, figs. 2; abs. in Jour. Roy. Micros. Soc. [London], 1911, No. 6, p. 743*).—The author agrees with the suggestion of Jeittees that the ancestor of domesticated dogs is to be found in the small Indian wolf (*Canis pallipes*), which has a well-marked supra-orbital crest. There is an exception, however, in the dog of ancient Egypt, recently discovered by Hiltzheimer, Gaillard, and Lortet, and which seems to have been derived from several species of jackal. The author does not agree with Studer's conclusion that the domestic dog is descended from a European species which became extinct in the Quaternary period.

**The poultryman's guide, compiled and edited by T. E. QUISENBERRY** (*Mountain Grove, Mo. [1912], pp. 249, figs. 187*).—This work is issued by the Missouri State Poultry Board, and is a compilation of information gathered from many sources and covering all phases of the poultry industry.

**Notes on the history of barred breeds of poultry, R. PEARL** (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 22 (1912), No. 5, pp. 297-308, figs. 3*).—These notes relate to the origin of the Cuckoo Pekin bantam and the Barred Plymouth Rock. There is a discussion of the probability of the barring factor arising de novo. The data given suggest the possibility that in the early history of the Barred Plymouth Rocks the males were heterozygous as regards barring instead of homozygous as at present.

**Campines in Belgium, England, and America, F. L. PLATT** (*Rel. Poultry Jour., 19 (1912), No. 2, pp. 266, 267, 330-334, figs. 4*).—An account of the characteristics of the Campine and Braekel breeds of fowl, and of the origin of the Campine-Braekel crosses.

**Increasing the egg yield by breeding, R. P. ELLIS** (*Rel. Poultry Jour., 19 (1912), No. 2, pp. 263, 301-306*).—This contains the views of a practical poultry-

man, who shows why, in his opinion, it is not practical to breed the 200-egg fowl.

**Bacteriological studies of newly laid eggs.** O. MAURER (*Kansas Sta. Bul.* 180, pp. 360-396, figs. 2).—The object of these experiments was to determine the amount of infection in eggs and the factors influencing it during their formation. After some preliminary experiments to determine the number of bacteria in the egg, this work was given up and work limited to determine the number of eggs infected.

There was a tendency for the infected eggs to occur in small groups of 2, 3, or even 4, although there were cases where this tendency did not occur. No endeavor was made to express this tendency in more concise mathematical form, because only alternate eggs had been subjected to bacteriological examination, and because the number of eggs being laid outside the trap nests was quite large.

As the result of the experiments the following conclusions were drawn: "Eighteen and one-tenth per cent of the total number of eggs analyzed showed bacterial growth at room temperature, while only 8.3 per cent showed growth at blood temperature. Of the infected eggs, 82 per cent were infected in the yolk, 25.9 per cent in the white, and only 7.9 per cent in both white and yolk. The bacterial content of eggs undergoes great seasonal changes, generally increasing with the rise in temperature. No definite relation could be traced between the bacterial content of eggs and their hatching qualities. No relation could be found between the age of the fowls and the bacterial content of their eggs. No definite influence of the fattening ration upon the number of eggs infected and upon their hatching qualities could be observed."

A bibliography is appended.

**The fertility of hen eggs.** D. F. LAURIE (*Jour. Dept. Agr. So. Aust.*, 15 (1912), No. 7, p. 723).—Most of the eggs were found to be fertile until 7 or 8 days after the cock was removed from the pen. None were fertile after 17 days.

**Contributions to the artificial incubation of fowls.** J. PAECHTNER (*Deut. Landw. Presse*, 39 (1912), Nos. 12, pp. 126, 127; 13, pp. 139, 140, figs. 9).—Tests made of an incubator, which is illustrated and described, are reported in detail.

**How to raise chicks.** P. T. WOODS (*Chicago*, 1912, pp. 123, figs. 33).—This book was written for the practical poultryman and covers the selecting, breeding, and management of fowls.

## DAIRY FARMING—DAIRYING.

**Practical lessons from the management of the university dairy herd.** G. C. HUMPHREY and F. W. WOLL (*Wisconsin Sta. Bul.* 217, pp. 3-34, figs. 4).—This contains data on milk production of the dairy herd during the 2 years following the report previously noted (*E. S. R.*, 22, p. 677).

The average record for 22 cows was 7,978.2 lbs. of milk and 352.51 lbs. of fat in 1909-10, and 8,536.3 lbs. of milk and 354.77 lbs. of fat in 1910-11. The value of the products for the 2 years was \$121.71 and \$114.41, respectively. The net profit per cow was reduced from \$69.16 the first year to \$48.69 the second year, due to the lower prices for dairy products and the higher prices for feed. Over 1 lb. of milk fat and 24 lbs. of milk were produced daily per cow during the winter months.

High protein rations were less economical than medium protein rations. It is recommended that some high protein roughage, as alfalfa and clover hay, be available on every dairy farm in order to reduce the cost of rations. During the first weeks of pasturage the cows gained in production but lost in weight,

but it is thought that this loss can be reduced to a minimum by feeding hay or silage during the first few weeks on pasture.

The individual records of the cows, schedule of prices for feed, and other data are presented in tabular form.

**The Illawarra dairy cattle, CAMDEN** (*Pastoralists' Rev.*, 21 (1912), No. 12, pp. 1254, 1255, figs. 5).—An account of the methods of dairying in the Illawarra district of New South Wales.

There is also an account of the origin of a general purpose breed of cattle, known as the Illawarra, an association of which was formed in 1910. The requirement for registration is not pedigree, but in the case of cows is a record of performance. If a cow "has not more than 2 permanent teeth up she must yield at the rate of at least 8 lbs. of commercial butter per week. With more than 2 teeth, and not less than 4, she must give at least 9 lbs.; with 4 teeth and not more than 6 she must give 10 lbs.; and a cow with more than 6 permanent teeth must make at least 12 lbs. of commercial butter per week. . . . The standard for bulls shall be that 4 of their progeny have qualified for the herd book, and that they score not less than 75 per cent of points on the scale of points approved by the association."

**The cattle of Touraine, J. B. MARTIN** (*Bul. Mens. Off. Renseign. Agr. [Paris]*, 11 (1912), No. 2, pp. 197-211).—This article discusses the breeds of cattle in Touraine, and gives records of the milk production and the work of the breeder's associations.

**Bacteria as friends and foes of the dairy farmer, W. SADLER** (*London, 1912*, pp. XV+112, pls. 4).—A small book on dairy bacteriology, written in a popular style for the producer and consumer of dairy products.

[Dairy investigations], **H. L. RUSSELL** (*Wisconsin Sta. Bul.* 218, pp. 26-30, fig. 1).—A brief report of progress at the station in making Cheddar cheese from pasteurized milk, the rôle of bacteria in ripening Cheddar cheese, manufacture of buttermilk cheese, the cause of mottles in butter, a new homogenizing device, improvement of the quality of the milk supply, and the distribution of dairy factories in Wisconsin.

**Judging dairy products by points, M. A. O'CALLAGHAN** (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 1, pp. 25-30).—This contains the score cards used in teaching students to judge milk, fresh cream for table use, cream for butter making, butter, and cheese.

**A synthetic milk medium, H. A. WHITTAKER** (*Amer. Jour. Pub. Health*, 2 (1912), No. 3, p. 162).—A method for preparing an artificial milk for use as a standard medium for exact bacteriological determination is described as follows:

"Fifteen gm. of pure caseinogen are dissolved in 100 cc. of a 1 per cent solution of sodium hydroxide in distilled water. Eighteen to 24 hours may be required for a complete solution. After the caseinogen is dissolved the solution is diluted to about 900 cc. with distilled water. Ten gm. of lactose and 0.1 gm. of calcium chloride are added and the solution made up to 1,000 cc. with distilled water. It is then neutralized and made +0.3 with N/1 hydrochloric acid, using phenolphthalein as an indicator. This medium is sterilized in an autoclave at 107° for 20 minutes. The finished product should be a clear, transparent solution. When the medium has a reaction of +0.3 about 24 hours are usually required for coagulation with an active strain of *Bacillus coli*. When the reaction is neutral a somewhat longer time may be required to produce similar results. This medium has been thoroughly tested on the routine test for *B. coli* and apparently meets all requirements."

**The food value of clean milk.—The demand for clean milk: The reasonableness of it, R. M. WASHBURN** (*Agr. of Mass.*, 58 (1910), pp. 47-63).—It is

pointed out that milk has not been estimated by the consumer at its full value as a food. Many suggestions are given for the production of pure milk.

**Ozone and the sterilization of milk.** W. P. BLISS (*Jour. Meat and Milk Hyg.*, 1 (1911), Nos. 6, pp. 324-330; 7, pp. 400, 401; 9, pp. 505-508; *Rev. Gén. Lait*, 8 (1911), Nos. 22, pp. 505-515, fig. 1; 23, pp. 532-539; 24, pp. 553-559).—Milk treated with ozone acquired an unpleasant taste, which could not be reduced except to a trifling extent by aeration. Ozone delayed curdling, and the length of time which elapsed between the curdling of the raw specimen and the ozonized milk increased roughly as the concentration increased. In general slow ozonization was of more value than fast ozonization.

Bacterial counts showed that ozone destroyed an appreciable number of the bacteria, on the average about 40 per cent, but too low a percentage to be considered efficient in preserving milk. The remaining bacteria are apt to grow faster than those in the untreated samples, so that although at first the numbers may be reduced 40 per cent, in 24 hours they may be as high as, or higher than, in the raw milk.

"The marked irregularity in the results of the experiments proves that the preservation of the milk depends upon the nature of the milk rather than the amount or concentration of the ozone, and that ozonization can not be depended upon to produce definite increase in this length of preservation."

**The utilization of skim milk.** C. KNOCH (*Die Magermilch-Verwertung in den Molkereien*. Leipzig, 1912, 2. ed., rev. and enl., pp. 1X+249, figs. 42).—This book treats of the methods of testing skim milk, the economic significance of skim milk, and methods of manufacture into other products. The methods of using skim milk for making kefir, yoghurt, milk cognac, milk chocolate, margarin cheese, ziger, milk bread, diastasin, and milk-molasses stock feeds are described. Details are given for manufacturing milk sugar, condensed milk, powdered milk, butterine, and many patented products such as galalith, casein cement, casein lime, casein plaster, an imitation of amber, shoe polish, plasmon, nutrose, sanatogen, casein soap, and material used for insulating.

**Kefir and yoghurt.** M. HOBENADEL (*Pharm. Zentralhalle*, 52 (1911), Nos. 50, pp. 1337-1342; 51, pp. 1371-1378; 52, pp. 1491-1494).—This article describes the methods of preparing kefir, yoghurt, and other fermented milks, and discusses their dietetic and therapeutic values.

**Kefir** (*Merck's Ann. Rpts.*, 24 (1910), pp. 39-63; *Merck's Arch.*, 13 (1911), No. 12, pp. 389-395; 14 (1912), No. 1, pp. 14-18).—This describes different methods of preparing kefir. A bibliography is appended.

**The chemical composition of Mecklenburg butter in the years 1899-1903, and 1910-11.** W. D. KOOPER (*Ztschr. Untersuch. Nahr. u. Genussmil.*, 23 (1912), No. 5, pp. 198-205).—A large number of analyses showed that there were seasonal variations. Butter made in summer had a higher fat content and iodine number, and a lower Reichert-Meißl number and a smaller percentage of solids-not-fat, than winter butter.

**Varieties of cheese.** C. F. DOANE and H. W. LAWSON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 146, pp. 78).—This is a revision of a bulletin previously noted (*E. S. R.*, 20, p. 181). A few additional varieties of cheese have been included.

**The present position of the cheese ripening problem.** O. JENSEN (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, pp. 202-209; *Molk. Ztg. Berlin*, 22 (1912), Nos. 12, pp. 133, 134; 13, pp. 145, 146).—This is a lecture given at the Fifth International Dairy Congress at Stockholm, and consists of a summary of investigations on the ripening of cheese.

**The cheese of Forez and D'Ambert.** ARDOUIN-DUMAZET (*Jour. Agr. Prat.*, n. ser., 21 (1911), No. 26, pp. 811-813).—The typical cheeses made in the depart-

ment of Puy-de-Dôme, which are known as "fourmes du Forez et D'Ambert" are cylindrical in shape and 25 cm. long by 13 cm. in diameter. The dairy methods used in making these cheeses are extremely primitive. A peculiarity is the method of ripening, which is accomplished by placing the cheeses on the ground in a cellar and covering them with earth, over which spring water is allowed to flow. Molds develop in the earth causing many of the cheeses to deteriorate in quality and to become unfit for export. The inside cuts of the best cheeses have an appearance and taste quite similar to Roquefort, but are not so dry as Septmoncel and Sassenage made in the southwest of France.

Swiss cheese exports in 1910, L. VON HENNET (*Mitt. Fachberichterstat. K. K. Ackerb. Min. [Vienna], 1911, No. 7, pp. 54, 55; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Discases, 2 (1911), No. 6. p. 1417*).—Statistical data on the exports of cheese, most of which is sent to France, the United States, and Germany. The exports to Italy have declined in the past few years owing to the development of dairying in northern Italy.

### VETERINARY MEDICINE.

Immunity, J. CITRON, trans. by A. L. GABBAT (*Philadelphia, 1912, pp. XIII+209, pls. 2, figs. 27*).—This publication deals with the methods of diagnosis and therapy and their practical application, and considers chiefly the human aspect. Among its contents are the following: Laboratory equipment, active immunity, tuberculin diagnosis, tuberculin therapy, toxin and antitoxin, the toxins of the higher plants and animals and their antibodies, ferments and antiferments, agglutination, precipitins, bacteriolysins and hemolysins, method of complement fixation, technique of the complement fixation method, phagocytosis, opsonins and bacteriotropins, and passive immunity.

Immunity, protective vaccination, and serum-therapy, A. DIEUDONNÉ (*Immunität, Schutzimpfung und Serumtherapie. Leipzig, 1911, 7. ed., rev., pp. VII+243, figs. 5*).—This is the seventh revised edition of this work (E. S. R., 23, p. 481).

Experimental bacteriology and the infectious diseases, with particular regard to immunity, W. KOLLE and H. HETSCH (*Die Experimentelle Bakteriologie und die Infektionskrankheiten, mit besonderer Berücksichtigung der Immunitätslehre. Berlin and Vienna, 1911, vol. 1, 3. ed., rev. and enl., pp. XVI+496, pls. 49, figs. 68*).—This is the first volume of the third revised and enlarged edition.

Experimental bacteriology and infectious diseases, W. KOLLE and H. HETSCH (*Die Experimentelle Bakteriologie und die Infektionskrankheiten. Berlin and Vienna, 1911, vol. 2, 3. ed. enl., pp. VII+497-968, pls. 49, figs. 111*).—This is the second volume of this text-book, which deals with diphtheria, tuberculosis, botulism, ulcus molle, infections caused by the *Bacillus pyocyaneus*, hemorrhagic septicemia of animals, hog cholera, swine plague, swine erysipelas, diseases caused by spirochetes, syphilis, the most important morphological and biological characteristics of protozoa, amoebic dysentery, flagellate infections particularly trypanoses, coccidial diseases, malaria, piroplasmoses, rabies, foot-and-mouth disease, pox in man and animals, mold fungi and budding fungi, ankylostomiasis, trichinosis, filariasis, and critical remarks in regard to the etiology of some infectious diseases of which the cause has not been discovered. An appendix is included which deals with the cultivation of bacteria, the most important staining methods, and methods for fixing and imbedding tissue.

Manual of bacteriology, R. MUIR and J. RITCHIE (*London, 1910, 5. ed., pp. XXIII+688, pls. 6, figs. 174*).—This is the fifth edition of this well-known work, which has been brought up to date.

The yearly report of the progress made in the field of the pathogenic micro-organisms, edited by P. VON BAUMGARTEN and W. DIEBELT (*Jahresber. Path. Mikroorgan.*, 24 (1908), pp. XII+1136).—This is a review of the literature issued in the year 1908 on bacteriology and protozoology.

Report of the fifteenth annual meeting of the United States Live Stock Sanitary Association (*Rpt. U. S. Live Stock Sanit. Assoc.*, 15 (1911), pp. 191).—Among the more important papers presented in this report are the following: Bovine Tuberculosis, Its Problems and Control (pp. 51-56), by V. A. Moore; New Methods of Tuberculin Testing (pp. 56-62), by K. F. Meyer; Tuberculosis—Summary of Methods and Results to Date, with Suggestions (pp. 76-78), by A. D. Melvin; Dourine in Horses, Covering Investigations in Iowa (pp. 79-83), by A. W. Miller; The Cattle Fever Tick Proposition (pp. 106-111), by E. M. Nighbert; Infectious Abortion in Cows and Mares (pp. 114-120), by E. S. Good; Outline of Experimental Work on Infectious Abortion of Cattle (pp. 120, 121), by W. Giltner; Contagious Abortion of Cattle (pp. 121-123), by W. P. Larson; Treatment of Hog Cholera with Attenuated Virus (pp. 125, 126), by A. T. Peters; Researches on Hog Cholera (pp. 129-135), by M. Dorset; Hog Cholera—V. B. Vaccination (Virulent Blood) (pp. 135-140), by M. H. Reynolds; and Report on the Nomenclature of Swine Diseases (pp. 142, 143), by V. A. Moore et al.

The following papers are presented in the appendix: Serum Diagnosis of Glanders and Other Animal Diseases (pp. 165-172), by J. R. Mohler; Rabies (pp. 172-175), by S. W. Ward; Control of Glanders in Minnesota (pp. 175-178), by C. E. Cotton; The Probable Influence of the Open Water Trough in the Spread of Glanders (pp. 178-181), by A. T. Kinsley; Further Report on Arsenical Dips as Remedies for Cattle Ticks (pp. 181-186), by B. H. Ransom; and Experience in Eradicating Tuberculosis from a Herd (pp. 186-188), by N. S. Mayo.

Some of the features of sanitary police work as applied in the federal quarantine service, R. N. HICKMAN (*Amer. Vet. Rev.*, 40 (1912), Nos. 5, pp. 591-600; 6, pp. 748-756).—A paper presented at the forty-eighth annual convention of the American Veterinary Medical Association, held at Toronto, August, 1911.

Clinical diagnostics of the internal diseases of domestic animals, B. MALKMUS (*Chicago, 1912, 4. ed.*, pp. X+259, pl. 1, figs. 57).—This is a translation by D. S. White and P. Fischer of the fourth revised and enlarged edition of the author's *Grundriss der Klinischen Diagnostik*.

The subject is taken up as follows: The diagnosis of diseases (pp. 11-17), anamnesis (pp. 18-20), method of examination (pp. 21-30), general part of the examination (pp. 31-74), special part of the examination (pp. 75-221), and specific examinations (pp. 221-251).

The animal parasites of cattle and wild animals recorded as occurring in the Belgian Kongo (*Bul. Agr. Congo Belge*, 2 (1911), Nos. 1, pp. 116-120; 3, p. 427).—This list, arranged by districts, records the locality and hosts of animal parasites of the Belgian Kongo.

The hydrocyanic acid content of three varieties of *Andropogon*, J. SCHRÖDER and H. DAMMANN (*Chem. Ztg.*, 35 (1911), No. 155, pp. 1436, 1437).—The varieties here discussed are *A. sorghum saccharatum*, *A. sorghum vulgare*, and *A. sorghum halepense*. The experiments reported were carried on in Uruguay, following the loss of cattle which had been fed upon sorghum.

The plants were cut at different periods in their growth and chemical analyses made to determine the hydrocyanic acid content with the result that all 3 varieties were found to contain it during the growing period. The content diminished with the growth of the plant and none was found in the seeds.

The application of nitrate of soda was found in nearly all cases to increase the amount of hydrocyanic acid present. In drying the plants a part of it disappeared so that the straw contained less than the green plants.

*Amount of hydrocyanic acid in sorghum at different periods of growth.*

Date.	Height of plant (unfertilized).	Period of growth.	Hydrocyanic acid content.			Stage of cutting.
			In unfertilized plants.	In plants fertilized with nitrate of soda.	Increase through application of nitrogen.	
<i>A. sorghum saccharatum.</i>

The toxic effects of three varieties of *Andropogon*, J. SCHRÖDER and H. DAMMANN (*Agron.*, 2 (1911), No. 10, pp. 283-290).—This paper relates to the studies of *Andropogon sorghum saccharatum*, *A. sorghum vulgaris*, and *A. sorghum halcensis*, as noted above.

Some studies on cotton-seed meal poisoning, C. W. EDGERTON and H. MORRIS (*Louisiana Stas. Bul.* 134, pp. 3-35).—This is a report of investigations, which have extended over a period of more than 2 years, from which the following conclusions are drawn:

"Cotton seed and cotton-seed meal does contain a toxic principle which is poisonous to certain animals. Cotton seed, itself, seems to be more toxic than the ordinary commercial cotton-seed meal. Different lots of cotton seed and cotton-seed meal show a considerable variation in toxicity.

"The toxicity of the cotton-seed meal does not seem to be affected by the fungi which rot the cotton bolls and enter the cotton seed. Cotton seed from plants affected with the cotton wilt, or black root disease, are less toxic than cotton seed from healthy plants. This decrease in toxicity in this seed is not due to the premature ripening of the seed, because seed ripened on plants that had been cut down showed as much toxicity as seed from healthy, uninjured plants.

"Heating cotton-seed meal or cotton-seed kernels for a long period at a high temperature decreases the toxicity to a considerable extent. A very short heating of the cotton-seed kernels, followed by an extraction of the oil, apparently does not decrease the toxicity. Another factor enters here, however,

which must be considered. This heated meal is much more palatable than the raw kernels and animals eat considerably more of it. Animals make better gains on this meal than on the kernels, though they die as soon, or even sooner, than animals on the raw kernels.

"The heating to which the kernels are subjected in the oil mill is probably sufficient in most cases to reduce the toxicity to some extent, though this reduction is usually not enough to remove all danger from feeding susceptible animals.

"The careful fermentation of the kernels or meal seems to reduce the toxicity to a considerable extent.

"All the cotton varieties that were tested that were grown on the same plot of ground during the same season, showed no difference in the toxicity.

"Sea Island seed obtained from Porto Rico was extremely toxic.

"We have no evidence whatever to show that pyrophosphoric acid has anything to do with cotton-seed meal poisoning."

Reference is made to the investigations of Crawford, previously noted (E. S. R., 22, p. 502).

**On the action of Senecio alkaloids and the causation of hepatic cirrhosis in cattle, A. R. CUSHNY (Proc. Roy. Soc. [London], Ser. B, 8 (1911), No. B 570, pp. 188-190).—**This is a preliminary report of experiments with the 2 alkaloids found in *Senecio latifolius*, made chiefly upon cats.

"The symptoms induced are of 2 kinds, acute, and subacute. The acute symptoms commence with nausea and salivation, extremely accelerated respiration, and, somewhat later, violent clonic convulsions under large doses. These acute symptoms generally pass off in the course of 2 or 3 hours, and the animal appears perfectly well very often for the next 2 or 3 days or longer. Some loss of weight may occur during this time, and then the subacute symptoms are introduced by a stool of rather loose consistency, loss of appetite, and in some cases vomiting. The animal then becomes weak and disinclined to move, and passes into a condition of apathy, stupor and coma, death following by failure of the respiration. These later symptoms succeed each other rapidly, death occurring within 24 to 48 hours after the first subacute symptoms. . . .

"Post-mortem appearances varied a good deal in different animals. There was often found an unusual amount of fluid in the abdominal cavity, sometimes of a bright yellow color. Small ecchymoses were sometimes found in the omentum, and fat deposits in the abdomen. The stomach contained black masses of half-digested blood, and the duodenum also contained some effused blood mixed with mucus. The liver was swollen and congested, and the gall bladder was generally distended with very dark colored viscous bile, which could only be expressed from it with difficulty. Small hemorrhages were often found in the lungs, pancreas, kidney, and some other organs. . . . In chronic poisoning no symptoms, except loss of weight, were elicited until the drug had been given for over a month. . . . The animal then died with the same appearances as in subacute poisoning. . . . The 2 alkaloids sent to me induced the same symptoms and the same changes, and seem to be equally toxic."

**A study of the renal epithelium in various types of acute experimental nephritis and of the relation which exists between the epithelial changes and the total output of urine, W. DE B. MACNIDER (Jour. Med. Research, 26 (1912), No. 1, pp. 79-126, pls. 4).—**"From the experimental data presented in this investigation the following conclusions appear allowable:

"Cantharidin, potassium dichromate, uranium nitrate, and sodium arsenate produce in the dog an acute nephritis in which both the vascular and the epithelial elements of the kidney are involved. The histological study shows that the vascular element of the kidney is first affected and that the rapidity

with which the epithelium is involved depends principally upon the nephrotoxic substances employed in producing the nephritis. Uranium nitrate and potassium dichromate usually produce a tubular nephritis much earlier than either cantharidin or sodium arsenate.

"In the early stages of the nephritis from these poisons, when there is anatomical evidence of vascular injury and either slight or no anatomical evidence of epithelial injury, the output of urine is increased. Later in the nephritis, when histologically the vascular pathology may not be increased in severity but when the epithelium has become involved, the output of urine is reduced or an anuria is established. Those nephrotoxic substances which have the most marked affinity for the tubular epithelium are the substances which most rapidly cause either a reduced output of urine or an anuria, while those nephrotoxic substances, such as arsenic, which cause an early and a pronounced vascular injury, with late epithelial involvement, are the poisons which have the least tendency to produce an anuria.

"In the experiments detailed in this study which have shown either a pronounced decrease in the output of urine or an anuria, there have constantly been associated epithelial changes, which would produce in different degrees an obstruction of the lumen of the tubules. In those experiments in which the output of urine has not been decreased, and in those experiments in which the output of urine was increased beyond the normal, such epithelial changes either did not exist or they were histologically slight."

**The precipitation reaction for anthrax, HOBSTETTER** (*Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 7, pp. 117-119, figs. 2).—The chief difference between Ascoli's test (E. S. R., 26, p. 375) and Pfeiler's reaction lies in the fact that in the first named the precipitating reagent is prepared by heating the suspected material in a boiling water bath for a few minutes with physiological salt solution, and in the latter the material is rubbed up with chloroform and porcelain sand and extracted with carbolized salt solution. The latter method has the disadvantage of requiring about 7 hours for the preparation of the extract, but with the former the reaction is not so intense.

**The diagnosis of anthrax by the Ascoli reaction, A. LEBRE** (*Arch. R. Inst. Bact. Camara Pestana*, 3 (1912), No. 3, pp. 379-397, figs. 7).—This reaction (E. S. R., 26, p. 375) furnished very satisfactory results, even when the material to be tested was putrid.

**Aggressin immunization against symptomatic anthrax, O. W. SCHÖBL** (*Abh. m Science, n. ser.*, 35 (1912), No. 893, p. 237).—"Briefly, the results of the experiments are as follows: The existence of aggressin in blackleg edema has been proved, since the sterile edema fluid aids infection by hindering the natural protective apparatus of the organism. Phagocytosis chiefly is inhibited. It is nontoxic even in much larger quantities than the amount necessary to change a sublethal dose of symptomatic anthrax bacilli into the lethal dose. Repeated injections of sterile edema fluid leads to a considerable degree of immunity. The animals are not only immune themselves, but also yield serum that protects normal animals from subsequent infection. Such a serum shows the presence of antibodies demonstrable both *in vitro* and *in vivo*, the most striking characteristic being its favorable effect upon the phenomenon of phagocytosis.

"In the subcutaneous circumscribed infiltration following artificial infection, immunized animals may under certain circumstances harbor virulent symptomatic anthrax bacilli. Therefore, the immunity can not be considered bacteriolytic. The immunity consists of a complete or partial inhibition of the growth of symptomatic anthrax bacilli in the body of the immunized animal. If the immunity is not sufficient to suppress completely the growth of bacilli, they multiply locally and are still able to produce toxin. The difference

between antitoxic and antiinfectious immunity is in the case of symptomatic anthrax quite evident. The fact frequently observed in the experiments that immune animals may harbor in their bodies symptomatic anthrax bacilli, fully virulent for normal animals, is worthy of consideration from an epidemiological standpoint.

"The method of immunization with aggressin is advantageous in that the inoculating material is a sterile fluid, hence the danger of making bacillus carriers or setting up a virulent infection through the vaccinating material is avoided."

**Anthrax and tick fever, W. H. DALRYMPLE** (*Amer. Vet. Rev.*, 40 (1912), No. 6, pp. 757-764).—This is a continuation of the paper previously noted (E. S. R., 26, p. 678), and deals with Texas or splenic fever, and the cattle tick and its eradication.

**Vaccination against blackleg in Bavaria, T. KITT** (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 9 (1911), No. 1-2, pp. 99-119).—Vaccination against symptomatic anthrax has been carried on for the last 20 years in Bavaria. The vaccine used in most instances was prepared by heating with live steam the powdered muscle of animals affected with blackleg. A table is given taking in the years 1898 to 1909, inclusive, which gives the number of vaccinated and unvaccinated animals, and the mortality statistics in each case. The mortality in the case of the vaccinated animals was very low.

In addition to these some tests are reported in regard to the preparation of vaccine for blackleg free from living spores, and the author points out some of the disadvantages which are encountered in sterilizing vaccine according to the various methods.

**The viability of human carcinoma in animals, C. L. WILLIAMS** (*Proc. Roy. Soc. [London]*, Ser. B, 84 (1911), No. B 570, pp. 191-195).—"Portions of human carcinoma implanted into animals were observed during the first 5 days to retain their vitality and to exhibit mitoses after implantation. After the expiration of this period no evidence of vitality was observed. Mitosis was markedly inhibited within 24 hours of implantation, while the life of the implanted cells was abolished less rapidly."

**In regard to the behavior of Wassermann's reaction with rabbits affected with dourine, F. M. MEYER** (*München. Med. Wchnschr.*, 58 (1911), No. 44, pp. 2318, 2319; *abs. in Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 7, p. 127).—The Wassermann reaction (complement fixation reaction for syphilis) was positive in from 1 to 4 weeks after infection. In some cases the reaction was present before the symptoms.

**Experiences and observations in regard to combating foot-and-mouth disease by Steffen's method, N. MEYER** (*Illus. Landw. Ztg.*, 32 (1912), No. 9, pp. 66, 67).—This treatment consists of dusting yeast powder in the blebs and erosions of the buccal cavity and the use of yeast ointment for the foot lesions. The results obtained with the method were comparatively good.

**Foot-and-mouth disease, B. BANG** (*Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 1-15).—A paper read before a meeting at the Royal Veterinary and Agricultural College, Copenhagen, on October 16, 1911.

**The precipitin-diagnostic reaction for glanders in horses, S. COSTA and A. FAYET** (*Compt. Rend. Soc. Biol. [Paris]*, 70 (1911), No. 4, pp. 147, 148).—The results show that Miessner's and Panisset's reactions can be obtained when mallein is injected into sound horses. This property may persist for at least 24 hours.

**Trypanosomes found in Canadian mammals, E. A. WATSON and S. HADWEN** (*Parasitology*, 5 (1912), No. 1, pp. 21-26, pls. 2).—The species described as new are *Trypanosoma leporis-sylvaticus*, found in the cotton-tail bush rabbit

(*Lepus sylvaticus*), at Lethbridge, Alberta; *T. peromysci*, found in northern deer mice (*Peromyscus maniculatus*, *P. nebraccensis*, and other species) at Lethbridge; *T. citelli*, found in the ground squirrel (*Citellus richardsoni*), at Lethbridge; *T. rutherfordi*, found in the blood of a cow at Mount Lehman, British Columbia; *T. evotomys*, found in a vole (*Evotomys saturatus*) at Mount Lehman; and *T. soricis*, found in the blood of a wandering shrew (*Sorex vagrans*) at Mount Lehman.

**Trypanosoma americanum**, a common blood parasite of American cattle, H. CRAWLEY (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 145, pp. 39, figs. 15*).—This is a report of studies of the nonpathogenic trypanosome described by the author in a bulletin previously noted (*E. S. R.*, 22, p. 281).

A résumé of the literature, first presented, is followed by reports of (1) the examination of cultures, including seasonal variation in the number of trypanosomes in blood, effect on the trypanosomes of keeping the blood before cultures were made, results obtained with measured quantities of blood, and general results of cultural work; (2) observations on fresh material, including attempts to discover the trypanosomes in freshly drawn blood, evolution of the trypanosomes in culture, movements of trypanosomes in cultures, the process of multiplication, and motility of the trypanosomes; and (3) observations on fixed material, including morphology of the forms in the blood and in culture, and cytology of the forms in culture.

The conclusions drawn are as follows: "*T. americanum* lives, in all probability as a typical trypanosome, in the blood of perhaps 75 per cent of yearling and adult American cattle, but is not present in young calves. It comes very close to *T. wrublewski* of the European bison, and may be only a variety of that species. Removal from the circulating blood stimulates multiplicative energy, apparently merely as the result of a cooler environment. Removed from the cow and placed under appropriate conditions, multiplicative energy runs far in advance of growth energy; hence the trypanosomes divide and redivide very rapidly, and in consequence become smaller than the blood forms. At the end of a few days, multiplicative energy weakening, the organisms have an opportunity to grow and to reach their normal size. The adults are at first very slender, but in time increase in breadth and may become very large. As the cultures reach and pass their maxima the individuals become club-shaped and eventually transform into rounded or oval elements, provided each with a long flagellum.

"Changes in the morphology of the nuclear system, and in the texture and chemical nature or composition of the cytoplasm, accompany changes in the facies of the entire organism. A distinguishing character is the situation of the trophonucleus, which is normally at the union of the anterior and middle thirds."

A bibliography of 13 titles is appended.

The infection of mules by *Trypanosoma hippicum* through mucous membranes, S. T. DARLING (*Jour. Erypt. Med.*, 15 (1912), No. 4, pp. 367-369).—The experiments with mules here reported indicate positively that *T. hippicum* can penetrate the mucosa of mules. From this it is assumed that murrina may be transmitted during copulation. It is stated that the disease, which has been eradicated in the Canal Zone, is still present in parts of the Republic of Panama in villages and along the trails, and that cases have been detected in native ponies near the zone line.

Investigations in regard to tuberculosis in milch cows, G. Cosco (*Centbl. Bakl. [etc.]*, 1. Abt., Orig., 61 (1911), No. 1-2, pp. 59-63).—Tuberculosis may be conveyed from one bovine to another by the agency of the feces, which contains the specific living and virulent organism. Some cows, which to all

appearances have sound udders, eliminate tubercle bacilli with the milk. No tubercle bacilli could be detected in the urine. The above results were obtained with 9 bovines.

**Nontuberculous milk in Guernsey,** H. D. BISHOP (*Brit. Med. Jour.*, 1912, No. 2665, p. 217).—"Until 1906 tuberculosis was apparently unknown amongst Guernsey cattle, but it was then introduced by cattle reimported after having been to England for exhibition. This reimportation is now forbidden and drastic laws have been passed compelling the slaughter of all infected cattle, and granting state compensation. As a result the disease has been practically stamped out, and of the 1,364 animals exported during the past 3 years, all of which were treated with tuberculin, only 6 were found to be affected. . . .

"The forms of human tuberculosis chiefly caused by bovine tuberculosis (tuberculous glands of neck, abdominal tuberculosis, and lupus) are consequently exceedingly rare in the island of Guernsey."

**In regard to the course of bovine tuberculosis,** C. TITZE (*Berlin. Tierärztl. Wchenschr.*, 28 (1912), No. 6, pp. 98-101).—A detailed description of the cycle of tuberculosis from the time of infection to either the death of the animal and its offspring, or to the resolution of the tuberculous process.

**In regard to detecting pulmonary tuberculosis in bovines,** O. MÜLLER (*Berlin. Tierärztl. Wchenschr.*, 28 (1912), No. 10, pp. 179-183).—A discussion in regard to the various existing methods of catching sputum from bovines for the purpose of diagnosing pulmonary tuberculosis. Tests with sound and tubercular bovines showed that the method devised by the author, and similar to that of Scharr and Opalka (*E. S. R.*, 26, p. 679), is of value.

**The tuberculin test; its value and proper uses,** J. LAW (*Tribune Farmer* [N. Y.], 40 (1912), No. 537, pp. 1, 2, figs. 2).—This article deals with the factors which influence the value of the tuberculin test, and discusses its present status.

**On a nematode in the connective tissue of bovines,** M. PIETTRE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 9, pp. 620-623).—The frequent finding of calcareous deposits about the femoro-tibial articulation led the author to conduct the investigations here reported.

The lateral and capsular ligaments were found to be invaded by a filarial parasite, to which the name *Ouchocerca bovis* has been given. It occurs only in fibrous tissue and almost exclusively in the thick part of the lateral and capsular tendons of the femoro-tibio-patellar articulation. The external ligament is more often invaded than is the internal. The external tibio-tarsal ligament was found to be invaded in one instance but never the cervical ligament.

This parasite is of importance pathologically because of the disorders which it causes at the place of articulation of the tendons and the resulting periarthritis.

**Onchocerciasis in imported meat,** H. WILLIAMS (*Pub. Health* [London], 25 (1911), No. 1, pp. 8-10).—It is stated that on a minute examination made on cutting up a number of flanks and briskets the percentage of *Spiroptera reticulata* infestation of meat arriving in England from Australia was found in many cases to be over 80, and in some cases to reach 100. This infestation is of increasing importance, since the quantity of frozen meat arriving in England from Australia is greatly exceeding that of previous years.

"When the first consignment was examined, it was thought that this parasite existed only on the surface, but a more careful examination of subsequent consignments revealed the fact that it was also to be found embedded in the deeper connective tissues, especially on the flanks and briskets. . . . The hind quarters, on careful examination, were also found to be affected, chiefly in the vicinity

of the stifle or knee joint, and a few scattered nodules on the surface of the meat. The percentage found affected is also very high, as will be seen from the following examination of the consignments from only 2 vessels. Of 4,617 hind quarters examined, 2,839, or 61.49 per cent, were found to contain the parasite *S. reticulata*. Of 805 hind quarters examined, 564, or 70 per cent, were found to be affected. . . . The worm in the hind quarters is generally situated deeply, requiring considerable cutting in order to find the worm and, when found, to insure that the whole of the worm, with the surrounding tissues, has been removed."

It is stated that the Commonwealth of Australia has instituted a rigorous system of inspection of beef for export and that in the future all flanks and briskets from fore quarters will be cut off before being allowed to leave the country.

The inheritance of spirochetel infection in *Argas persicus*, E. HINDLE (*Proc. Cambridge Phil. Soc.*, 16 (1912), No. 6, pp. 457-459).—The experiments reported indicate clearly that once a tick becomes infected with *Spirochata gallinarum* its offspring of the first generation is infective in all its stages, and moreover that the infection is transmitted to the second generation. "It is evident, therefore, that once the Argas of any locality become infected with spirochetosis it will be very difficult to eradicate the disease."

Investigations relative to arsenical dips as remedies for cattle ticks, B. H. RANSOM and H. W. GRAYBILL (*U. S. Dept. Agr., Bur Anim. Indus. Bul.* 144, pp. 65, pls. 6, fig. 1).—This bulletin reports the details of 22 dipping experiments of which 12 were with arsenic, soda, and pine-tar dips; 1 with arsenic, soda, and pine-tar dip containing emulsified crude petroleum; 2 with arsenic and zinc sulphate dip; 2 with arsenic-alum dip; 1 with sodium arsenate dip; 1 with sodium sulpharsenite dip; 2 with potassium arsenite dip containing soap; and 1 with repeated applications of the arsenic, soda, and pine-tar dip. In most of the experiments the arsenical solution used was a modification of the Mayo formula, the amounts of arsenic varying from 8 to 12 lbs., and of sal soda from 24 to 45 lbs., for each 500 gal. of dip, in different instances. When pine tar was used it was added in the proportion of 1 gal. to each 500 gal. of dip. In some of the experiments arsenical dips of somewhat different composition were used. The amount of arsenic in solution in the various dips, expressed in its equivalent of arsenic trioxid, varied from 0.16 to 0.495 per cent.

"The effects of the dips upon the cattle in the various experiments were almost invariably slight. . . . Cattle not infested with ticks, dipped repeatedly in a dip containing an equivalent of about 0.22 per cent arsenic trioxid at intervals of 2 and 3 weeks gained less in weight than other uninfested cattle kept under the same conditions undipped, but it is uncertain whether this difference was due to the dipping. In all cases in which cattle were dipped or sprayed once or twice in arsenical dips containing an equivalent of from 0.16 to 0.24 per cent arsenic trioxid the injurious effects observed were confined to the action of the dips upon the skin, and scarcely ever was this action more than very mild, though in some cases the animals were treated in hot weather when the injurious effects from dipping are especially likely to appear. The signs of the effects of dipping on the skin in various instances became evident in from 3 to 9 days after the treatment, at which time a more or less well-marked epidermal exfoliation or dandruff-like peeling of the superficial layers of the skin appeared, confined as a rule to the dewlap, neck, escutcheon, inner side of thighs, and scrotum. No marked inflammation preceded the exfoliation, though occasionally a slight irritation of the skin in places was observed."

The authors conclude that "cattle may be safely dipped or sprayed with arsenical dip containing an equivalent of 0.24 per cent arsenic trioxid or less,

and the treatment once repeated 7 or more days later, the only injury to be expected as a rule being more or less epidermal exfoliation, and sometimes slight soreness or tenderness of the skin, local in character."

The experiments fully confirmed the observations of various investigators and practical users of arsenical dips who have found that ticks are very sensitive to arsenic. Little is known, however, as to the avenue by which the arsenic enters the body of the ticks. After treatment with an arsenical dip the vast majority of the young adult females die before they reach the engorged stage, and the younger they are the less likely are they to survive and become engorged.

"In 6 experiments the cattle were found to be free from engorged ticks 3 to 5 days after the first treatment, in 4 other experiments they were free 7 to 9 days after treatment, in another they were nearly free 5 days after treatment, in another experiment all that were examined were free from engorged ticks 8 days after treatment, and in 2 other experiments the cattle were nearly free from engorged ticks 8 days after treatment."

In order to obtain data bearing upon the question of the fate of ticks which reach engorgement and fall from cattle subsequent to dipping, engorged ticks were collected from the cattle in the various experiments immediately after treatment and on successive days thereafter and kept under observation. "Whereas in many of the lots from treated cattle all of the ticks died without ovipositing, in most cases some of the ticks deposited eggs, the percentage of ticks ovipositing usually being low, although in rare instances as high as 100 per cent." Ticks from treated cattle which survived to deposit eggs nearly always deposited a much smaller number than ticks from untreated cattle, and moreover, they rarely hatched. Out of approximately 70 lots of ticks from treated cattle, only 4 lots deposited eggs which hatched.

"Judging from these results it would appear that the hatching of eggs deposited by ticks which survived treatment with arsenical dips is a rather rare occurrence. Furthermore, it has been noted that the larvae from eggs deposited by females which have been subjected to arsenical solutions are frequently in such a weakened condition that they can not emerge from the eggshell, or they may become lodged in the opening of the ruptured shell and fail to extricate themselves, or show such slowness of movements after emerging as to make one believe that they could not effect a successful attachment after reaching a host, a condition of the larvae which has also been noticed in the case of eggs subjected to unfavorable conditions, such as low relative humidity and low temperatures."

The data relative to the ticks removed from cattle after treatment and their corresponding control from untreated cattle, and to engorged ticks dipped in the laboratory, are presented in tabular form.

"Very few male ticks were found alive on cattle later than a day or two after treatment, and it is probable that most of these were ticks which were in the nymphal stage at the time of treatment. It may therefore be concluded that arsenical dips are highly efficacious so far as the destruction of male ticks is concerned. . . . The vast majority of nymphs were killed by a single treatment. In several experiments, however, some of the nymphs survived and afterwards molted. . . . No instance was observed in any of the experiments of the survival of ticks in the larval stage after a single treatment with an arsenical dip."

The bulletin concludes with a discussion of the practical significance of results of experiments with arsenical dips, taking up the composition of the dip, method number, and frequency of applications, and handling the cattle.

A plan is given for a draining pen for cattle after dipping.

**Parasitic gastritis of sheep**, E. G. HASKELL (*Vet. Rec.*, 24 (1912), No. 1229, pp. 473-475).—It is stated that flocks of sheep in certain parts of the south-west of England have suffered severely from parasitic gastritis, due to *Strongylus cervicornis*, and that the mortality is still continuing. In west Somerset the greatest number of deaths was observed among ewes of all ages, though lambs a year old were also affected.

**The thermo-precipitin reaction as a general sero-diagnostic method; its use for diagnosing swine erysipelas**, A. ASCOLI (*Berlin. Tierärztl. Wchenschr.*, 28 (1912), No. 10, pp. 165-167, figs. 3).—This reaction (E. S. R., 26, p. 375) can be employed without difficulty for diagnosing erysipelas in swine. The technique is given in detail.

**Actinomycosis of the rectum in the horse**, H. MARKUS (*Tijdschr. Veeartsenijk.*, 38 (1911), No. 9, pp. 349-353, pl. 1; *abs. in Vet. Rec.*, 24 (1911), No. 1221, p. 339).—The author records a case of this affection in a 4-year-old Oldenburg mare.

**Studies on etiology of equine influenza**, N. S. FERRY (*Abs. in Science, n. ser.*, 35 (1912), No. 893, pp. 239, 240).—From each case of equine influenza studied the streptococcus described by Schütz was isolated from the trachea. The *Bacillus equisepticus* was never noted. In addition, a similar organism was isolated from the blood of 34 out of 63 cases. The organisms grew well symbiotically with the staphylococcus in broth cultures. It was possible for the organism to pass through the Berkefeld and Chamberland filters, and in all probability it assumes a minute size during its life cycle, as indicated by Basset (E. S. R., 26, p. 384).

The author was not able to differentiate between this organism and the streptococcus isolated from abscesses in the case of strangles. "If this proves to be the same organism that is found in strangles and also contagious pneumonia, and it is agreed by all authorities that the streptococcus found in strangles is the cause of that disease, then, we believe, we are justified in putting forward the argument that this streptococcus is the cause of the symptom complex we have termed 'influenza,' and that strangles and contagious pneumonia are not clinical entities, but complications of influenza due either to secondary infections or to extension of the primary disease."

**In regard to the treatment of lymphangitis by "606,"** J. BRIDRÉ, L. NÈGRE, and G. TROUETTE (*Bul. Soc. Path. Exot.*, 4 (1911), No. 6, pp. 380-383).—The disease in all of its phases in horses and mules was treated successfully with Salvarsan (Ehrlich's 606). In all instances the diagnosis was confirmed by finding the micro-organisms in the pus. Only 1 out of 9 animals died.

**Filaria immitis of the dog**, D. ZIBORDI (*Clin. Vet. [Milan], Scz. Prat.*, 33 (1910), Nos. 43, pp. 684-689; 44, pp. 697-704; 45, pp. 713-717; 46, pp. 734-740; *Jour. Trop. Vet. Sci.*, 7 (1912), No. 1, pp. 68-84).—A review of the subject is followed by reports of studies of 6 cases, together with a bibliography of 41 titles.

## RURAL ENGINEERING.

**Rules governing matters coming before the State Board of Irrigation, Highways, and Drainage** ([*Lincoln, Nebr.*, 1912, p. 27]).—This pamphlet gives the rules of procedure adopted by the State Board of Irrigation, Highways, and Drainage of Nebraska governing matters coming before it relative to claims, applications, dams, petitions, and contests.

**Irrigation pumping with electrical energy** (*Elect. World*, 59 (1912), No. 15, p. 804).—An example of the use of electrical energy for irrigation pumping is noted, embracing an area of 10,000 acres and with 69 motor-driven pumping

plants having capacities ranging from 900 to 1,700 gal. per minute. The pumping system is owned by the farmers of the region, but the energy is developed by a private plant. It is claimed that the cost of the energy is less than 1 ct. per kilowatt hour.

The amount and frequency of irrigation as determined by the physical properties of the soil, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 8, pp. 481-487; *Prog. Agr. et Vit. (Ed. l'Est Centre)*, 33 (1912), No. 12, pp. 360-366; *Rev. Vit.*, 37 (1912), No. 955, pp. 460-464; *abs. in Rev. Sci. [Paris]*, 50 (1912), I, No. 9, pp. 284, 285).—Experiments were made to determine (1) the amounts of water most favorable to crops when applied at equal intervals, and (2) the influence on yield of the application of equal quantities of water at irregular intervals.

The results show that there is ordinarily a decided waste of water, as the real needs of plants are greatly exceeded. The authors are of the opinion that, although it is impossible to attain the ideal in the application of water, efforts should be made to approach it.

An interesting agricultural, hydraulic problem in Algeria, J. SAVORNIN and I. POUGET (*Bul. Soc. Hist. Nat. Afrique Nord*, 1910, Nos. 7, pp. 104-108, fig. 1; 8, pp. 123-127).—The authors present a solution to the problem of utilizing the basin and waters of a salt lake for irrigation purposes, viz. to divert the neighboring running water and rainfall waters into the lake and provide an outlet sufficient to lower the lake surface about 6 meters. These works, it is claimed, will reduce the surface evaporation, freshen the water, and keep a good supply of water on hand.

A diagram for converting square feet into acres in irrigation and drainage work (*Engin. and Contract.*, 37 (1912), No. 16, p. 450, fig. 1).—A combined table and diagram is presented and explained, giving accurate results to the third decimal place.

Cooperative methods in farm drainage, R. H. CLEMENS (*Canad. Farm*, 6 (1912), No. 13, p. 3, figs. 3).—The trouble and expense encountered in the ordinary drainage ditching methods are pointed out, and the economic and time-saving advantages of cooperative drainage-ditching operations are discussed.

Standard tests of drain tile and sewer pipe, A. MARSTON and A. O. ANDERSON (*Proc. Iowa Engin. Soc.*, 23 (1911), pp. 39-46).—This is a paper read before the Iowa Engineering Society, at Des Moines, February 15-17, 1911.

The need of standard tests for drain tile and sewer pipe is pointed out and 3 standard test requirements are recommended, viz. the percentage of absorption, the bearing strength, and the modulus of rupture, which requirements involve the absorption test and the bearing strength test. A discussion is given of various methods of making absorption and bearing strength tests, and specifications are recommended for making standard tests of this nature.

In the standard absorption test the specimens are to be of a definite size and number, perfectly dry and clean, and are to be weighed and then immersed in pure soft water for 24 hours. They are then to be taken out, reweighed, and the percentage of absorption calculated by the formula  $\frac{W'-W}{W}$  = the percentage of absorption, in which  $W$  is the original weight and  $W'$  is the weight after immersion.

The standard bearing strength test embodies the following: The test specimens are to be whole, full-sized, dry, average tile, 5 in number. They are to be weighed before the test and then bedded above and below in dry washed sand for one-fourth the circumference of the pipe. The top bearing must have a true plane lower surface of rigid material capable of distributing the test

load without any appreciable bending and the test load is to be applied at the exact center of this top bearing. The frames for top and bottom bearings are to be of sufficiently heavy timber to avoid any bending by side pressure. The test load is to be applied continuously and gradually without shock or disturbance to the tile and no considerable time is to elapse between load additions. The bearing strength is taken equal to the total top load plus the weight of the frame and bearing timbers, sand, etc., plus five-eighths the weight of the pipe. This load is to be divided by the length of the pipe in feet to give the bearing strength in pounds per foot.

The modulus of rupture in pounds per square inch is then calculated by the formula  $F = \frac{b \times r}{t^2}$ , in which  $b$ =bearing strength per linear inch,  $r$ =the mean radius of the tile in inches, and  $t$ =the minimum thickness of the tile at the top and bottom in inches.

A method of making tests on drain tile, A. N. TALBOT and D. A. ABRAMS (*Engin. Rec.*, 65 (1912), No. 14, pp. 384, 385, figs. 2).—This is a paper read before the Eighth Annual Convention of the National Association of Cement Users. It points out the need for inexpensive adjustable, portable, and accurate testing machines for definite and important qualities of drain tile, and describes and gives tabulated results of 3 series of tests of tile with such a machine.

The machine consists essentially of a simple framework and a lever for applying the load by means of dead weight. The framework is adjustable and can hold any diameter of tile up to 42 in. The top and bottom loading blocks are 4 by 6 in. material and provided with bearing edges and rubber hose cushions for distributing the load uniformly over the length of the tile. The lever is 4 ft. 6 in. long and the dead load is applied to its end. The machine weighs 225 lbs. and the authors claim that it should not cost more than \$18.

In using the machine, the tile is rolled into place on the bottom loading block which has 2 half round strips 2 in. apart for rest and the framework is adjusted to the size of the tile. The top loading block is placed on the top of the tile, the lever fitted into place, and the dead load is applied at the lever's end.

Whatever the method of test may be, it is necessary finally to determine the relation between the strength of the piece tested and the strength needed in the structure. The method of loading along a line at the top and bottom of the tile is selected because of its simplicity, and because it gives simple, direct, and fairly uniform results for varying conditions of tile. The bending moment developed, the modulus of rupture, and the load per foot of length of pipe of given size can be determined by these tests. The authors give as the expression for bending moment the formula  $0.16 Qd$ , in which  $Q$  is the concentrated load applied to the crown, and  $d$  the mean diameter. The formula for modulus of rupture is given as  $f = 0.96 Qd l^2$ , in which  $l$  is the length of tile and  $t$  the thickness along the top and bottom elements.

Preserving good roads, L. W. PAGE (*Sci. Amer. Sup.*, 73 (1912), No. 1892, p. 210).—The use of motor-truck trains in the maintenance of trunk highways is discussed and the necessary equipment noted.

An automobile equipment is suggested which will include all the apparatus and facilities necessary to employ efficiently a repair gang of 8 men in the maintenance of the road surface over 100 miles of roadway or more. Three significant requisites mentioned are that the cost of the equipment should be kept consistently low and within the range of customary expenditures, that novel or specially constructed apparatus should be avoided, and that the outfit should be so flexible in its makeup as to serve readily a variety of utility or lend itself to peculiar requirements under varying conditions. An approximate estimate of the total equipment is as follows: Machine with steel dumping

body, \$6,000; electric hoist, \$250; horsepower spreader with rotary pump and piping, \$700; 500 gal. tar kettle, \$300; double kerosene burner outfit, \$200; and tools and accessories, \$50; total \$7,500.

Changes noted in a tar exposed to traffic and weathering when used in a road surface, W. W. CROSEY (*Surveyor*, 41 (1912), No. 1055, pp. 526, 527).—The results of tests of the carbon-free extract of portions of a coal-gas tar-road surface, which had been exposed to weather and traffic for 3 years, are reported.

Among the changes noted, the lowering of the melting and initial boiling points is very marked. The opinion is expressed that the distillation of bituminous compounds is materially affected by the presence of free carbon, and that a secondary analysis should be made of all bituminous materials containing it in appreciable amounts.

Highway laws of the United States (*Good Roads*, n. ser., 3 (1912), No. 14, pp. 215-223).—Brief digests are given in this article of the laws affecting road administration, construction, and maintenance in the several States.

Concrete construction on the live-stock farm (*U. S. Dept. Agr., Farmers' Bul.* 481, pp. 32, figs. 24).—This bulletin deals with the construction of concrete feeding floors, manure pits and basins, and dipping vats.

The advantages of a concrete feeding floor pointed out are cheapness, durability, sanitary qualities, saving of grain, labor, and manure, and neat appearance. The essential details of construction of concrete feeding floors for cattle, hogs, sheep, and poultry are discussed under the subheads of materials, location, grading, drainage, necessary equipment, apportioning and mixing the concrete, general method of construction, and curing. A short statement of cost is also given.

The wastefulness of the ordinary methods of manure storage is pointed out and directions are given for the proportioning of concrete and the general construction of concrete manure basins and shallow manure pits. The important points to be considered in the planning, construction, and care of concrete dipping vats are also pointed out and discussed, and the construction details are given.

The action of alkali salts upon Portland cement, E. BURKE and R. M. PINCKNEY (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 5, pp. 317-326).—Previously noted from another source (*E. S. R.*, 25, p. 490).

Practical barns in use on northwestern farms, S. K. HAUGEN ET AL. (*Farmer*, 31 (1912), No. 16, pp. 584, 588-591, figs. 23).—Plans and descriptions are given of barns as worked out and proved satisfactory by actual farm experience.

Economy in sanitary barn construction, H. G. LOTTER (*Farmer*, 31 (1912), No. 16, p. 583, figs. 3).—The author describes economic methods of sanitary cow barn construction, and discusses, as the main essentials of construction, drainage, warmth, ventilation, light, and easy handling of feed and refuse.

Cement silo construction, M. S. KING (*Cement and Engin. News*, 24 (1912), No. 4, pp. 123-125).—The author points out the essential requirements of silos and deals especially with masonry silos, discussing their lasting qualities and such construction details as reinforcing, foundations, doors, and roofs.

Open-air poultry houses for all climates, P. T. WOODS (*Chicago*, 1912, pp. 86, pl. 1, figs. 44).—Many types of open-air poultry houses are illustrated and described.

Electricity in agriculture and reference to central rural plants, H. WALLEM (*Die Elektrizität in der Landwirtschaft und deren Beziehungen zu Überlandzentralen. Diss. Tech. Hochschule Karlsruhe*, 1910, pp. 46, figs. 21).—This pamphlet deals with the use of electricity in the operation of agricultural

machinery, reviewing the most important agricultural implements, discussing the use and advantages of electricity in the operation of plows and thrashing machines, elevators, unloading apparatus, and drying plants, discussing electro-culture and rural electric roads for farm traffic, and calculating the entire amount of electrical energy needed on a 2,000-acre farm. The economics of central agricultural electric plants and the prospective demand for electrical agricultural machinery are also discussed.

**A grouped electrical unit, II.** D'ANCHALD (*Jour. Agr. Prat., n. ser., 23* (1912), No. 4, p. 119, fig. 1).—An electrical unit for supplying electric light on a farm is described consisting of a low-speed gas-motor, dynamo, rheostat, and storage battery.

**Gas lighting for the farm,** F. B. CARPENTER (*Minn. Farm Rev., 17* (1912), No. 4, pp. 74-76, figs. 3).—The author deals briefly with small gas generating systems for farms, describing the gasoline gas, acetylene gas, and blau-gas systems. He points out the advantages relative to safety, durability, and efficiency of these gas systems over the ordinary oil, gasoline, and kerosene methods of lighting and cooking, and discusses initial cost and cost of operation.

**Farm and barn conveniences** (*Farmer, 31* (1912), No. 16, pp. 593-595, 597, figs. 5).—Brief descriptions are given of some of the modern devices for lightening labor and saving time on the farm, among which are the farm power house, hydraulic ram, hay tools in the barn, barn door hangers, dairy room, milking machines, litter carriers, barn lighting and ventilating, gates and fences, and improved water supply.

**Farm implements,** P. MCCONNELL (*Jour. New Zeal. Dept. Agr., 4* (1912), No. 2, pp. 89-93, fig. 1).—This article deals with the use, care, and development of farm machinery in general, and shows the need of a knowledge of applied mechanics among farmers.

**New agricultural machinery, especially for motor cultivation,** MARTINN (*Ztschr. Landw. Kammer Schlesien, 15* (1911), Nos. 39, pp. 1222-1225, fig. 1; 40, pp. 1262-1269, figs. 3; 41, pp. 1291-1298, figs. 7; 42, pp. 1324-1328, figs. 5; 43, pp. 1355-1357, figs. 5; 44, pp. 1387-1392, figs. 8).—A discussion is given of the operation, initial cost, and cost of operation of steam and internal combustion motor plows. A number of improved agricultural implements are described and their costs discussed, among which are improved hay forks, potato diggers, turnip headers, manure spreaders, milking machines, straw stackers, subsoil plows, and side delivery hay rakes.

**The engine gang** (*Canad. Thresherman and Farmer, 17* (1912), No. 4, pp. 10, 11, 14, 16, 18, 20, figs. 39).—This is a brief review of the development of the ordinary plow through the ages, and deals especially with the development of the engine gang plow during the past few years, discussing the improvements in construction and operation of several special types.

**Diagram of ditching plow, with details for construction and approximate cost,** T. B. WILSON (*N. Y. Dept. Agr. Circ. 45, 1911, pp. 3, figs. 3*).—A list of materials, dimensions, approximate cost, etc., of a ditching plow is given, accompanied by a lettered diagram.

**Two machines in one** (*Farm Machinery, 1912, No. 1070, p. 16, fig. 1*).—A combination of hay tedder and side delivery hay rake is described.

**Motor-driven milking machines,** F. D. BURR (*Elect. World, 59* (1912), No. 16, pp. 855-857, figs. 2).—A system of motor-driven milking machines is described, consisting of a motor-driven rotary vacuum pump to the suction end of which is connected a pipe line which extends through the cow barns and communicates with the milking machines.

**Horses and stock currying machines** (*Wiener Landw. Ztg., 62* (1912), No. 20, p. 240, figs. 5).—Machines for currying horses and cattle are described, and

cost data are given for hand and motor driven currying machines and combination currying and shearing machines.

## RURAL ECONOMICS.

[How will an increase in crop output affect prices and incomes?] (*Farmers' Rev.*, 44 (1912), No. 10, p. 259).—This article illustrates by the table below, compiled from census reports, that an increase in output of farm products in the United States will not necessarily mean a decrease in price per unit or in total amount received.

*Total output, value, etc., of farm products in the United States, 1900-1910.*

Crop.	Total output.			In-crease in out-put.	Total value.			In-crease in value.
	1900	1905	1910		1900	1905	1910	
	<i>Bushels.</i>	<i>Bushels.</i>	<i>Bushels.</i>	<i>P. ct.</i>				<i>P. ct.</i>
Corn . . .	2,105,102,516	2,707,993,540	3,125,713,000	50	\$751,222,033	\$1,116,696,738	\$1,523,968,000	100
Wheat . .	522,229,505	692,979,489	695,443,000	33	323,515,177	518,372,727	621,443,000	92
Oats . . .	809,125,989	953,216,197	1,126,765,000	39	208,669,233	277,047,537	384,716,000	84
Potatoes	210,926,897	260,741,294	388,811,000	60	90,811,167	160,121,680	187,985,000	107

Other illustrations are given showing the total value of farm crops to have increased from \$5,017,000,000 in 1900 to \$8,926,000,000 in 1910. Nevertheless the total value of beans, peas, onions, and potatoes imported increased from \$5,092,932 in 1906 to \$8,273,371 in 1910.

From producer to consumer, M. C. SMITH (*Farmers' Rev.*, 44 (1912), No. 14, pp. 4, 18, figs. 2).—This is a popular article describing in more or less detail the establishment and success of a public market in Rockford, Ill., where producer and consumer are enabled to complete their marketing transactions without the aid of the middleman.

Farm management, W. M. HAYS ET AL. (*Minnesota Sta. Bul.* 125, pp. 7-44, pls. 5, figs. 10; *U. S. Dept. Agr., Bur. Plant Indus. Bul.* 236, pp. 7-44, pls. 5, figs. 10).—The term "farm management" is said to include "the selection, planning, organization, and development of the farm and the daily and yearly conduct of the farm business," and "the object sought in research in farm management is to secure the elementary facts which must be utilized in organizing and conducting the business of the farm in such a way as to give the maximum of products, profits, and enjoyment to the owner and to the farm family, to supply farm products in the best way to all who need them, and gradually to increase the productivity of the soil."

In addition to discussing and outlining the scope of farm management this portion of the bulletin presents a number of results obtained from investigations made for the purpose of determining the best methods of crop rotation and the cost of producing farm products in Minnesota (*E. S. R.*, 21, p. 188). It also discusses and illustrates by means of tables and charts methods of planning the farm and its business organization, planning fields for rotation of crops, comparing cropping schemes with standard rotation, showing profits and losses, the use of cost statistics of farm products, value of farm products, etc.

The outlook for agriculture in the Canal Zone, W. A. TAYLOR (*U. S. Dept. Agr., Rpt.* 95, pp. 39-49, pls. 2).—From a study of the climate, soil, crops, and other conditions bearing upon the development of agriculture bordering the Panama Canal, observation discussions are given of the humid tropical climate; broken topography of the surface and the clayey nature of most of the

soil; present crops and methods; present and prospective demand for fresh vegetables; fruits, milk, and poultry products; scarcity of live stock; character of the population; and land titles and tenures.

It is concluded that large farming operations are impracticable on account of the broken topography; that the staple crops best adapted to the conditions are corn, cassava, yams, sugar cane, plantains, bananas, and upland rice; and that the most promising outlook is the development of a permanent mixed tropical agriculture with a distinct horticultural trend, in which hand labor of tropical origin will be the main dependence for tillage.

[Agricultural resources in Italy], A. PUGLIESE (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 5-6, pp. 317-413).—Tables state by provinces the areas and normal annual yields of various regions of Italy and the yields secured in 1909-10, the total number of farm animals in each of the countries of Europe, the number per thousand inhabitants and per thousand hectares, and other data of a similar nature. The greater portion of the article is made up of lists of the field plants most commonly found in each of a considerable number of localities in Italy.

Agricultural statistics in Roumania, 1911 (*Miu. Agr. Statis. Agr. Românici*, 1911, pp. 37).—A statistical report of the minister of agriculture, showing the area and production of the leading crops in Roumania, together with tables illustrating to what extent crops were damaged by hail, drought, frost, etc. for the year 1911.

[Agricultural statistics] (*Statis. Abs. Brit. Self-Gov. Dominions [etc.]*, 48 (1896-1910), pp. 296-356).—Official statistics are given showing the acreage and production of the leading agricultural crops in the British self-governing dominions, crown colonies, possessions, and protectorates from 1896 to 1910 inclusive, together with exports and imports of agricultural products by countries.

Report on the land settlement scheme, H. WALWYN (*Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. Grenada, 1910-11*, pp. 18-20).—Regarding the land settlement scheme in Grenada initiated in 1910 by the appropriation of £5,000 by the government for the purchase and allotment of lands, the land officer reports that about 153 acres have been purchased at a cost of £495 and subdivided into 47 allotments of 2, 3, 4, and 5 acres. The allotments are to be sold to peasants upon the approval of an application and the payment of 25 per cent of the purchase money as a first installment. The peasant then receives a permit to occupy the land, the remainder of the money is divided into 9 equal parts, and after the expiration of 3 years he pays an annual installment of one of these parts, with 5 per cent interest on all unpaid purchase money each year after the payment of the first installment.

Applications have been received for 32 allotments, and 27 of them approved. Two allotments of 4 and 5 acres have been reserved for the purpose of experiments and demonstrations, to enable the land officer to distribute to allottees plants free or at very little cost.

Agricultural cooperation [in France], A. GAULIN (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 93, pp. 259-262).—This is a report from the Marseille consular district showing that agricultural syndicates for collective buying, handling, and selling agricultural products have been of considerable advantage to the farmers of the district, the sales to farmers being made at cost price, plus a commission of 1 to 3 per cent for running expenses. If there are any profits they are not distributed but are frequently applied to the purchase of machinery for collective use, which has aided many of the small farmers in lowering their cost of production.

It is claimed that the syndicates have brought about reductions of from 30 to 40 per cent in the prices of fertilizers, and aided materially in lowering the

prices on other commodities, besides checking frauds and compelling the delivery of pure products.

**Agricultural credit in France**, H. SAGNIER (*Le Crédit Agricola en France. Paris, 1911, pp. XV+158*).—This book presents a historical summary of the organization and growth of agricultural credit organizations in France, showing the work of the early organizations, agricultural syndicates, and banks, and the application of legislation to the movement up to 1910.

The act of 1897 provided for the establishment of small local credit societies or village banks, together with a district bank, through which they receive their share of the funds allotted by the State out of the loan and royalties paid to it by the Bank of France. The local societies or village banks may secure additional funds from the district bank, which it obtains from the ministry of agriculture free of interest for a period of 5 years, with power to renew, and to the amount of four times its paid-up capital. Loans may be made for periods not exceeding 25 years for the purpose of aiding in the production and sale of agricultural produce, erection of farm buildings, etc.

At the end of 1910 there were 96 district banks and 3,338 village banks with a membership of 152,000. Loans made during the year amounted to 70,533,340 francs and repayment of loans to 61,388,806 francs. See also a previous note (E. S. R., 23, p. 291).

**Systems of rural cooperative credit** (*U. S. Senate, 62. Cong., 2. Sess., Doc. 574, 1912, pp. 47*).—This document gives a detailed outline of cooperative credit systems in European countries as compiled from publications of the International Institute of Agriculture. It illustrates the workings of the personal and real credit systems, and shows the peculiar functions and success of each, together with the work of the rural, local, popular, central, and general banks in various countries.

**Agricultural credit** (*U. S. Senate, 62. Cong., 2. Sess., Doc. 572, 1912, pp. 27*).—This document presents the general theory of cooperative credit and its application in France and other foreign countries; the uses to which rural credit may be applied, as personal necessities and public requirements; the guiding and working principles of the organizations; and the connection existing between the local rural credit banks and the district banks.

**German agricultural credit system**, H. C. PRICE (*Rural New Yorker, 71 (1912), Nos. 445, pp. 453, 454; 446, p. 487*).—This article treats in a general way of the system of German agricultural credit successfully operated for more than a century, showing the different organizations for credit and their relation to the ordinary farmer, and how they supply him with loans for long periods at rates of interest varying from 3 to 5 per cent. Features of the loans which make them especially favorable to the farmer are as follows: (1) The rate of interest at which they are made can not be raised; (2) they can not be called in except for specific reasons, such as the waste of the property or flagrant misuse of it; (3) the right is granted to pay back the loan in part or in whole at any time on giving notice the required length of time in advance, which is never over 6 months; and (4) by paying annually on the principal from 0.5 to 0.75 per cent of the loan, the loan is gradually paid off.

**Agricultural credit banks** [in Victoria], A. T. SHARP (*Jour. Dept. Agr. Victoria, 9 (1911), No. 12, pp. 800-805*).—This is a discussion as to the purpose of agricultural credit systems, their adaptation to different conditions; and their origin and growth in a number of countries.

Special attention is directed to the establishment, work, and growth of the Victoria credit bank organized in 1906 with a capital of £117, which has increased to £2,343 with 1,180 shareholders. Loans granted since its organization number 1,744, totaling nearly £19,000, paying an average dividend of 4.8

per cent per annum. Loans have been made for the following purposes: Liquidation of loans obtained at usurious rates; construction and repair of dwellings; deposits on land; purchase of horses, cows, and farm implements; and payments of university fees to enable students to complete their courses, etc. It is stated that only one loss has been sustained.

**Insurance against forest fires [in Germany]** (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 11 (1912), No. 2, pp. 212, 213).—The object of insurance against forest fires is stated as to compensate the owner for forests burned or for the expense of reforestation. The growing need for such insurance is said to be due to the increased number of industrial establishments and railways in the vicinity of forests, and the reforestation of uncultivated lands with such trees as the fir, pine, or other conifers, which more easily take fire than deciduous trees. The premium is fixed according to the kind and age of trees, varying from 0.25 to 4 marks per thousand.

### AGRICULTURAL EDUCATION.

**Reorganization of agricultural education.** R. J. HUERGO (*Reorganizacion de la Ensenanza Agricola. Buenos Aires, 1908, pp. 286, figs. 9*).—This is a report by the division of agricultural education to the minister of agriculture of Argentina on the reorganization of the system of agricultural education authorized December 27, 1907, and the work accomplished from January to July, 1908.

The new scheme includes higher instruction, special instruction of a technical-practical character adapted to local conditions, practical instruction for future agriculturists and horticulturists, and extension work. The higher instruction is now being offered by the Agricultural and Veterinary Institute at Buenos Aires and the agricultural and veterinary faculty of the National University at La Plata; the special instruction by the School of Agriculture and Husbandry at Cordoba, the School of Viticulture at Mendoza, and the School of Arboriculture and Sugar Technology at Tucuman, with their experiment stations; the practical instruction by the Practical School of Horticulture and Arboriculture at Casilda, the Practical School of Dairying at Bell-ville, the Practical School of Forestry at Benitez, the Practical School of Subtropical Agriculture at Posadas, and the Practical School of Fruit Culture at San Juan, all offering 3-year courses. The extension work includes practical courses for young people and adults, itinerant courses, correspondence, cooperative experiments, local gatherings and expositions, encouragement to agricultural associations and syndicates, and the organization of district agronomes. An article on the object of practical schools of agriculture, by P. J. Iribarne, regulations for various kinds of works, and data on the organization and courses of study of the practical schools, are appended.

**Agricultural work in the schools of Pulaski County,** H. L. ROGERS (*Purdue Univ., Dept. Agr. Ext. Bul. 3, 1912, pp. 11, figs. 10*).—This is an account of the 1909, 1910, and 1911 exhibits of the Pulaski County Corn Club, the results of these exhibits, and particulars concerning the 1912 contest.

**French itinerant agricultural domestic science schools,** A. DUCLOUX (*Indus. Lait. [Paris]*, 37 (1912), No. 10, pp. 145-167).—The author gives a brief account of itinerant domestic science instruction in France, results obtained in Oise, Pas-de-Calais, and Nord, the qualifications and preparation necessary in the teaching staff, and the outlines of a 3 months' course.

**Organization of agricultural women in Belgium** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 11 (1911), No. 4, pp. 639-644, pls. 2).—This article discusses the economic importance of women's work on the farm, and shows to

what extent they have organized in Belgium for the purpose of becoming more efficient in performing the duties which fall to their charge on the farm and in the home. It is noted that from a numerical standpoint the woman on the farm is a very important factor in Belgium social economy, there being 385,000 and 325,000 women employed, respectively, in commerce and industry, while no less than 514,000 are engaged in agricultural work, principally dairying and poultry raising.

The organization known as *Cercles de Fermières* was founded in 1906 with 2 "cercles" and 115 members. The "cercles" in 1910 numbered 74 and had a membership of 6,929. Their work of the organization is primarily agricultural extension instruction by means of lectures, libraries, shows, competitions, and the like, but also embraces the social and moral advancement of the rural population. Among the lectures and demonstrations given for the last few years the following subjects are noted: The fermière, her mission as house-mother, housewife, and farm assistant; practical poultry keeping; utilization and preserving of fruit; butter making; kitchen gardening; stable hygiene, and the rational feeding of cows; advantages of cooperative dairying; care of young farm animals; the preparation of food; the feeding and diseases of children; antituberculosis hygiene; care of clothes and furniture; farm book-keeping; the organization of agricultural banks; and the proper investment of money, etc. The lectures in 1906 numbered 4 and the attendance 90, and in 1910, 232 and 14,290, respectively.

The "cercles" may be organized in such a way as to secure benefits and subsidies from the ministry of agriculture.

**The teaching of farm management**, W. M. HAYS ET AL. (*Minnesota Sta. Bul.* 125, pp. 44-96, figs. 47; *U. S. Dept. Agr., Bur. Plant Indus. Bul.* 236, pp. 44-96, figs. 47).—An effort is made in this bulletin to bring the subject matter of farm management into better pedagogical form to serve as a guide in teaching farm management in the rural and higher agricultural schools. The following phases of the subject are discussed and illustrated: The teaching of farm management; teaching farm organization in consolidated rural schools; the key-map method of organizing the farm; and teaching farm management in agricultural high schools. The illustrations given are results of a special study in connection with the School of Agriculture of the University of Minnesota and the Minnesota Station.

The appendix contains instructions to students for planning a farm and gives plans of 17 different farms as prepared by students, together with the instructor's criticisms.

**The soil: Its use and abuse**, E. O. FIPPIN (*Cornell Reading-Courses, Soil Ser.*, 1911, No. 1, pp. 16, figs. 14).—The author discusses soil formation, soil types, humus, soil moisture, food supply, tillage, and soil improvement, and gives a list of publications of interest.

**Seed testing**, W. L. OSWALD (*Nature-Study Rev.*, 8 (1912), No. 1, pp. 12-21, figs. 9).—The object of this paper is to show how both purity and germination tests can be made in schools or at home without the use of expensive apparatus. A weed-seed case prepared by the seed laboratory of the Minnesota Agricultural Experiment Station, a germination box, and rack for holding ears of corn in the individual-ear germination test of corn are illustrated and described.

**Logging and lumbering or forest utilization**, C. A. SCHENCK (*Darmstadt, Germany*, [1912], pp. 189, figs. 270).—This is a text-book for forest schools dealing with both lumbering operations and wood manufactures.

**Some observations on bird families**, D. E. MINNICH (*Nature-Study Rev.*, 8 (1912), No. 1, pp. 24-31).—Observations are given of families of downy

woodpeckers, red-headed woodpeckers, brown thrasher, and wood thrush, collected by observers working in relays.

Our friend the horse, C. T. BENSON (*Mason City, Iowa, 1912, pp. 6*).—Suggestions for use in the fifth, sixth, seventh, and eighth grades of the rural schools are offered for the study of the horse, including directions for judging draft horses.

Incubation, I, II, F. T. FINCH (*Cornell Reading-Courses, Poultry Ser., 1911, Nos. 1, pp. 17-27, figs. 13; 2, pp. 29-41, figs. 15*).—These lessons discuss the principles of incubation, incubators and their fixtures, incubator cellars, oil supply, and the operation of incubators.

Knots, hitches, and splices, II. W. RILEY (*Cornell Reading-Courses, Rural Engin. Ser., 1912, No. 1, pp. 45-88, figs. 159*).—Directions and illustrations are given for making knots, hitches, and splices of use on the farm.

1911 autumn bulletin (*Columbus, Ohio: State Supt. Agr. Ed. [1911], pp. 29*).—This bulletin is issued for teachers by the State Commissioner of Common Schools and the supervisors of agricultural education of Ohio. It suggests an outline for fall nature study work for the first 6 grades, also of elementary agriculture for grades 7 and 8, in which a text-book of elementary agriculture should be used. A study of corn and helps for teachers, including literature and brief study outlines of wheat and other grains, weeds, insects, forage crops, dairying, and milk are given to be used in connection with the course of study, also suggestions for the development of the social life of the rural community.

1911-12 winter bulletin (*Columbus, Ohio: State Supt. Agr. Ed. [1911], pp. 12*).—This outlines nature study work for grades 1 to 6, inclusive, and gives suggestions for a study of farm animals, farm machinery, and soils for grades 7 and 8. Literature for the use of the teacher is suggested.

Housekeeping and household arts, ALICE M. FULLER (*Manila, 1911, pp. 178, pls. 17*).—This manual, while intended mainly as a guide for teachers, may be used as a text-book in the elementary schools or as a cookbook in the home. Instruction in sewing, cooking, housekeeping, hygiene, and ethics is outlined for seven grades. A list of equipment for an intermediate school, a glossary of terms used, recipes for cooking rice, and an index to recipes are appended.

Course in domestic science, [NEALE S. KNOWLES] (*Iowa State Col., Ext. Dept. Circ. 15, 1912, pp. 28, figs. 13*).—This course comprises 5 cooking lessons and 5 sewing lessons.

Reading in the farm home, MARTHA VAN RENSSELAER (*Cornell Reading-Courses, Rural Life Ser., 1912, No. 1, pp. 85-101, figs. 3*).—The author discusses the benefits of acquiring the reading habit, the choice of books and method of reading, and related topics. A list of agricultural reference books on poultry, dairying, horticulture, and general agricultural subjects, and suggested lists of nature books and books on home economics, are given.

Reading in the farm home, CAROLINE WEBSTER (*Cornell Reading-Courses, Rural Life Ser., 1912, No. 1, pp. 102-108, figs. 2*).—Lists of poems, outdoor books, books of inspiration, books for boys and girls, and technical books are suggested.

Report of the extension service for two years, 1909-1911, W. D. HURD (*Mass. Agr. Col. Bul., 4 (1912), No. 1, pp. 32*).—This is a report on the growth of the extension movement, what extension work is, and the organization and work of the extension service at the Massachusetts Agricultural College, including short winter and summer courses given at the college, special days for foreigners, agricultural organizations, etc., and instruction given away from

college; a summary of what the extension service has accomplished, and its future needs.

**Agricultural extension service, H. L. RUSSELL** (*Wisconsin Sta. Bul. 218, pp. 33-56, figs. 1*).—An account is given of the agricultural extension service, comprising (1) demonstrational and educational work carried on during the summer in the field, and (2) extension courses of instruction held during the winter months.

The demonstration work consists of practical field trials, demonstrations at state and county farms and at northern substations, fertilizer demonstration tests, manure conservation, manufacture and distribution of tuberculin, hog cholera vaccine demonstrations, and potato spraying. The college has aided in developing farmers' cooperative projects, such as community breeders' associations, community potato centers, cooperative silo building circuits, and drainage service.

The general extension work includes young people's grain growing contests, bankers' pure-bred seed circuits, the dissemination of pure-bred seed grains, agricultural work in rural schools, tests of dairy cows, the Wisconsin dairy cow competition, butter and cheese scoring exhibitions, distribution of pure-culture starters, milk and cream testing, press service, lectures, correspondence, and educational exhibits. A map is given showing the distribution of extension lecture work. The extension instruction comprises university farmers' courses held in February for men, women, and boys, a country-life conference, state farmers' courses, one-week farmers' schools held at different places in the State, school garden work, and farmers' institutes.

### MISCELLANEOUS.

**Twenty-fourth Annual Report of Georgia Station, 1911** (*Georgia Sta. Rpt. 1911, pp. 125-133*).—This contains the organization list, reports by the president of the board of directors and by the director of the station on its work during the year, and a financial statement for the fiscal year ended June 30, 1911.

**Twenty-fourth Annual Report of Maryland Station, 1911** (*Maryland Sta. Rpt. 1911, pp. XVIII+276, pl. 1, figs. 66*).—This contains the organization list, a report by the director on the work and expenditures of the station, a financial statement for the fiscal year ended June 30, 1911, and reprints of Bulletins 146 to 154.

**Report of the director, 1911, H. L. RUSSELL** (*Wisconsin Sta. Bul. 218, pp. 78, figs. 20*).—This contains the organization list, a report of the work of the station during the year, portions of which are abstracted elsewhere in this issue, brief summaries of the publications of the year, and a financial statement for the federal funds for the fiscal year ended June 30, 1911.

**Monthly Bulletin of the Department Library, February and March, 1912** (*U. S. Dept. Agr., Library Mo. Bul., 3 (1912), Nos. 2, pp. 37-69; 3, pp. 73-110*).—These numbers contain data for February and March, 1912, respectively, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

**Experiment Station Work, LXVIII** (*U. S. Dept. Agr., Farmers' Bul. 486, pp. 24, figs. 2*).—This number contains articles on the following subjects: The feeding of a grand champion steer and the utilization of dairy by-products as food.

## NOTES.

---

**Arizona University and Station.**—The first state legislature has granted appropriations of \$18,000 for the fiscal year which began July 1. These appropriations are for the maintenance of the date orchards, dry farming work, and farmers' institutes, and also provide for printing, repairs, and experimental work in horticulture.

The membership of the board of regents has been increased from six to nine, the personnel at present consisting of Governor G. W. P. Hunt, superintendent of schools C. O. Case, chancellor A. L. Waters, treasurer L. W. Wheatley, F. H. Hereford, and Dr. L. D. Ricketts.

E. Dana Trout has been succeeded as secretary of the station by C. C. Cable. C. N. Catlin has been appointed assistant chemist.

**Connecticut College and Storrs Station.**—The State Commission of Fisheries and Game is cooperating with the station in the breeding and rearing of quail and other game birds. The commission is furnishing funds with which to conduct the experiments, and the laboratory studies are being made at the station. The main problem under investigation at the present time is the quail disease which is responsible for the death of large numbers of the birds.

H. J. Bower, assistant in agronomy in Ohio State University, has been appointed assistant in agronomy in the college and station.

**Illinois University and Station.**—The honorary degree of doctor of laws has been conferred on Vice President T. J. Burrill, who is retiring under a pension from the Carnegie Institution after an active service of over forty years. A portrait of Jonathan B. Turner, well known as an early advocate of federal aid to agricultural education, has been unveiled in the Illinois Farmers' Hall of Fame.

**Maine Station.**—W. W. Bonns has resigned as associate horticulturist to become plant physiologist at the California Station, with headquarters at Riverside. George A. Yeaton has been appointed horticulturist, with headquarters at the station farm at Monmouth.

**Mississippi Station.**—Arthur F. Rolf has resigned as poultryman to become poultry husbandman at the Georgia Station, and entered upon his new duties July 20.

**Missouri University and Station.**—A chemical laboratory, to cost \$60,000 and to be used mainly for agricultural chemistry, is under construction. It is to be known as Schweitzer Hall, in memory of Dr. Paul Schweitzer, who was connected with the department of chemistry for nearly forty years.

W. W. Wobus, assistant in dairy husbandry, has resigned to become instructor in dairy husbandry at the Iowa College. C. E. Wilson, assistant in veterinary science, has resigned to engage in commercial work in connection with the manufacture of hog-cholera serum. Three additional assistants have been appointed as follows: R. R. Hudelson in agronomy, O. C. Smith in agricultural chemistry, and T. T. Tucker in veterinary science.

**Montana Station.**—Harold H. Morris, instructor in chemistry in the Michigan College, has been appointed assistant chemist, and entered upon his duties July 1.

**New Jersey College and Stations.**—The appropriations made at the last session of the legislature include \$100,000 for an agricultural building, \$12,000 for a dairy building, \$9,000 for the completion of the greenhouses, \$3,000 for the completion of the poultry plant, \$3,000 for roads and grading, and \$2,000 for repairs and improvements in the short course building. Generous appropriations were also made for the maintenance of the poultry and horticultural departments, and the annual appropriation for the short courses was increased from \$16,500 to \$20,000. The mosquito extermination work was granted \$25,000.

A new horse barn has been erected at the college farm, at a cost of about \$8,000.

The fertilizer, feeding stuffs, and insecticide laws were revised at the last session of the legislature, and a new seed law was enacted. John P. Helyar has been appointed seed analyst of the station.

Other appointments include, in the college, Dr. M. T. Cook as professor of plant pathology and Earle C. Stillwell as instructor in horticulture; and in the station, Arthur L. Zimmerman as fertilizer sampler, L. A. Ruzicka as greenhouse assistant, and A. L. Clark as assistant poultry husbandman. Dr. William D. Hoyt, instructor in botany, and Ray G. Voorhorst, instructor in horticulture, have resigned.

**New Mexico College and Station.**—The state legislature has recently appropriated \$30,000 for a new building, which will probably be used for the erection of a fireproof science hall. The regular state appropriation for maintenance has been increased to \$25,000 per annum.

W. H. Cunningham has been appointed assistant in animal husbandry, in charge of dairying. S. E. Merrill has resigned as assistant in horticulture.

**Cornell University and Station.**—Dr. Clyde Hadley Myers has been appointed assistant professor of plant breeding, to have general charge of the extension work in that subject, and Dr. Rhett Youmans Winters has been appointed instructor in plant breeding, to give special attention to the teaching. C. S. Wright and G. J. Burt have resigned as assistants in olericulture and floriculture, respectively, to engage in commercial work.

**North Carolina College and Station.**—Dr. Burton J. Ray, who has been instructor in chemistry in the college and assistant chemist in the station, will hereafter devote his entire attention to station work. T. B. Stansel, assistant chemist in the station, and F. W. Sherwood, instructor in chemistry in the college, have resigned to undertake graduate work at Cornell University, and will be succeeded respectively by N. G. Fetzer and F. B. Sherwood, both 1912 graduates of the college. John W. Nowell, Ph. D. (Johns Hopkins 1912), has been appointed to an additional instructorship in chemistry.

**Ohio Station.**—J. T. Rogers, Leo E. Melchers, and E. L. Nixon have been appointed assistants in the department of botany. Charles M. Fritz has been appointed assistant in the department of nutrition, vice R. C. Collison, who has accepted a position at the New York State Station.

**Texas College and Station.**—The main building, erected in 1876 at a cost of \$100,000, was destroyed by fire May 27. It contained the administrative offices, library, and class rooms for three departments.

H. L. McKnight has been succeeded as superintendent of the station farm by R. E. Dickson, a 1912 graduate of the college.

**Utah College and Station.**—At the annual meeting of the board of trustees, Dr. F. S. Harris was made director of the school of irrigation engineering. The scope of the school was somewhat enlarged, and Ray B. West appointed professor of agricultural engineering in addition to the present staff. The discontinuance of the preparatory courses in the college at the close of the next academic year was authorized.

Dr. Robert Stewart has been appointed to the newly established position of assistant director of the station; W. E. Carroll has been appointed assistant director of the school of agriculture. H. J. Webb, Howard Sweitzer, and C. L. Merrill, all 1912 graduates of the college, have been appointed assistants respectively in entomology, horticulture, and agronomy. Stephen Boswell, superintendent of the Nephi Farm, and F. Froerer, assistant in animal husbandry in charge of the cooperative cow-testing work, have resigned to engage in commercial work, and have been succeeded respectively by A. D. Ellison and John Wilson, both 1912 graduates of the college.

**Virginia Truck Station.**—L. L. Corbett has resigned as assistant in truck crops to accept a position with the Farm Management Investigations of this Department.

**Washington College and Station.**—At a recent meeting of the board of regents plans for a \$150,000 building, to be used jointly by the station and the departments of agriculture, horticulture, and extension work of the college, were authorized.

A department of extension work has been definitely organized in the college, in place of the former work in farmers' institutes and agricultural extension. The new department has been placed temporarily under the supervision of the head of the department of agriculture of the college, with R. C. Ashby, superintendent of farmers' institutes, in general charge of the details of the work. The completion of a staff of extension workers will proceed as rapidly as circumstances will permit.

Dr. H. B. Humphrey, plant pathologist of the station, has been made vice director, the appointment becoming effective July 1. N. Rex Hunt has resigned as assistant botanist of the station, and C. D. George, a 1912 graduate of the college, has been appointed assistant plant pathologist.

**Wisconsin University and Station.**—A four-day university exposition was held in May at which the agricultural work was prominently represented. A course in beekeeping is to be added to the curriculum with the new college year.

Three county representatives of the station have now been appointed, namely, F. D. Otis in Barron County, E. L. Luther in Oneida County, and G. R. Ingalls in Eau Claire County. A state appropriation of \$1,000 and a county appropriation of \$500 are available in each case. The work to be undertaken will include instruction in the county training school for teachers, and in farmers' courses, lectures, and demonstration work with farmers, and cooperation with individuals.

The station is to undertake the manufacture and distribution of hog-cholera serum. A new office building, foreman's cottage, fireproof seed vault, and barns are under construction at the Ashland substation.

Dr. B. H. Hibbard, professor of economics and political science at the Iowa College, has been appointed associate professor of agricultural economics.

**Prospective Agricultural Meetings.**—The Association of American Agricultural Colleges and Experiment Stations will hold its twenty-sixth annual convention at Atlanta, Ga., November 13 to 15; the American Association of Farmers' Institute Workers will also meet at Atlanta, November 11 to 13.

The twenty-ninth annual convention of the Association of Official Agricultural Chemists will be held at Washington, D. C., September 16 to 18.

## CONTENTS OF VOL. XXVII, NO. 2.

Editorial notes:	Page.
Fifth session of the Graduate School of Agriculture .....	101
Recent work in agricultural science .....	107
Notes .....	197

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemical methods, edited by Abderhalden.....	107
An introduction to the chemistry of colloids, Poschl, trans. by Hodgson.....	107
Introduction to colloid chemistry, Poschl.....	107
Physical chemistry of the cell and tissue, Höber.....	107
Chemistry of the cell, Gies et al.....	107
In regard to the chemistry of chlorophyll, Tsvett.....	107
Yearbook of chemistry, edited by Meyer.....	107
Investigations in regard to the precipitation of proteins, Vandevelde.....	107
The synthesis of fats by the action of enzymes, Dunlap and Gilbert.....	108
The variations in the phosphorus content of seeds, Lewoniewska.....	108
Action of phosphates upon the activity of proteolytic ferments, Iwanow.....	108
Some observations upon the assay of digestive ferments, Graber.....	108
Action of salts of the gold group upon saccharification of starch, Gerber.....	109
Action of salts of alkali metals upon saccharification of starch, Gerber.....	109
Action of some salts upon saccharification of soluble starch, Gerber.....	109
In regard to catalase, Grimmer.....	109
Examination of substances important in agriculture and the industries, König..	109
A quantitative method for small amounts of potassium, Mitscherlich et al. ...	109

	Page.
An improved Hollemann method for estimating phosphoric acid, Vitoria.....	110
Neutral ammonium citrate solutions, Patten and Robinson.....	110
Use of "nitron" for determination of nitrate nitrogen, Robinson and Winter..	110
Determining hygroscopicity by Rodewald-Mitscherlich method, von Romberg..	110
Determining the mineral substances in water and estimating hardness, Wunder..	111
Detecting and estimating nitrites and nitrates in water, Tillmans and Sutthoff..	111
A rapid preliminary test for detecting added water to milk, Tillmans.....	111
The determination of saccharose and detection of dextrin, Vollant.....	111
Constants of chicken and turkey fats, Ross and Race.....	111
Determination of gliadin and alcohol-soluble protein in wheat flour, Hoagland..	111
The testing of the quality of gliadin in flour, Apsit and Brocq-Rousseu.....	112
In regard to the acids in honey, Heiduschka.....	112
The differentiation of almonds from similar seeds, Hannig.....	112
Determination of malic acid, Dunbar and Bacon.....	112
The immersion refractometer for approximating the solids in vinegar, Remington	112
A method for the detection of small quantities of coumarin, Wichmann.....	112
The estimation of furfural by means of Fehling's solution, Eynon and Lane.....	113
Examination of certain milk testing apparatus, Tiemann.....	113
The determination of the acidity of milk, Rammstedt.....	113
Methods for fat most frequently used in milk chemistry, von Sobbe.....	113
Do volatile fatty acids occur in fresh whole milk? Kooper.....	113
A simple method for detecting butter prepared from heated cream, Hesse.....	114
Examination of crude and refined milk sugar, Burr and Berberich.....	114
The electrical conductivity of impure sugar solutions, Taegener.....	114
The unification of reducing sugar methods.—A correction, Walker.....	114
A measurement of the translucency of papers, Sammet.....	114
Change in the acid content of distilled vinegar stored in wooden casks, Behre..	114
Milk sugar, Burr and Berberich.....	114
The oil of Douglas fir; its composition and properties, Benson and Darrin.....	115

## METEOROLOGY—WATER.

A new service of agricultural meteorology in France, Klein.....	115
Monthly Weather Review.....	115
Meteorological observations, Patten and Seeley.....	115
The climate of Prince George's County, Alexander.....	116
Cold air drainage, Shreve.....	116
The relation between the amount of rainfall and of seepage, Luedecke.....	116
Water resources of the Penobscot River basin, Maine, Barrows and Babb.....	116
Surface water of south Atlantic coast and Gulf of Mexico, Hall and Mathers...	116
Surface water of Hudson Bay and Upper Mississippi basins, Follansbee et al..	116
Gaging stations maintained by U. S. Geological Survey 1888-1910, Wood.....	116
Artesian and subartesian waters, New South Wales, Mingaye and White.....	116

## SOILS—FERTILIZERS.

The soil forming processes and principles of soil classification, Kossovich.....	117
Soils of arid and of humid regions, Hilgard.....	117
Soil investigations in the United States, Henning.....	117
A contribution to the knowledge of Cuban cultivated soils, Müller.....	117
Soil investigations, Kelley.....	118
Origin, composition, and properties of manganiferous soils of Oahu, Kelley....	118
Modification of the method of mechanical soil analysis, Fletcher and Bryan...	119
The estimation of certain physical properties of soil, Auchinleck.....	120
Hygroscopicity and the value of physical analyses, Mitscherlich and Floess....	120
The drying of soils, Ritter.....	121
The oxygen content of soil water and its influence, Hesselman.....	121
Evaporation from irrigated soils, Fortier and Beckett.....	121
Effect of heat and oxidation on the phosphorus of the soil, Peterson.....	122
Determining the intensity of respiration of bacteria in the soil, Stoklasa.....	122
Toxic effects of "alkali salts" on soil bacteria.—II, Nitrification, Lipman.....	124
Maintenance of soil fertility: Plans and summary tables.....	124
Reaction changes in the soil by growth of plants and fertilizing, Maschhaupt..	124
Influence of phosphatic and potassic fertilizers on pastures, Chavan.....	125
After effect of fertilizing with potash rocks on moor soils, von Feiltzen.....	125
Experiments on kainit, potash salt, and phonolite, Schueidewind et al.....	125

	Page.
The availability of the potash in "rapakivi" and pegmatite granites, Aschan..	127
Factors influencing the availability of rock phosphate, Truog.....	127
Report of the Lyon nitrate prospect near Queen, N. Mex., Free.....	127
The present status of the artificial nitrogen fertilizer industry, Dafert.....	128
Some recent experiments with calcium cyanamid or nitrolime.....	128
Marl for soil improvement from various formations in Hanover, Rosenbach....	128
The sootfall of London: Its amount, quality, and effects.....	128
Fertilizers: Their source, purchase, and use, Smith.....	128
Fertilizers in 1912, Guffroy.....	128
Inspection and analyses of commercial fertilizers, Trowbridge et al.....	128
Commercial fertilizers.....	128
Tabulated analyses of commercial fertilizers, Frear.....	128
Licensed commercial fertilizers, 1912, Woll.....	128

## AGRICULTURAL BOTANY.

The function of manganese in plant growth, Kelley.....	129
The influence of manganese on <i>Aspergillus niger</i> , Bertrand and Javillier.....	129
Stimulating action of manganese and copper sulphates on plants, Monteuartini..	130
Wheat seedlings as affected by acid or alkali, Breazeale and LeClerc.....	130
New studies on narcosis in plants, Richter.....	130
Stimulation of plants through small quantities of poisonous substances, Fred..	131
Action of carbon bisulphid on germinability of grain, Morettini.....	131
The action of carbon bisulphid on the germination of wheat, Fantechi.....	131
Treatment of seeds with hydrogen peroxid, Miège.....	132
Hydrocyanic acid formation in germination of seeds, Ravenna and Vecchi....	132
Investigations on the germination of weed seeds, Munerati and Zapparoli.....	132
Dependence of the respiration of plants on the lipoids, Stanevich.....	132
Recent investigations on formation of starch in plant cells, Guilliermond.....	133
Glycogen in phanerogams and its relation to oxalate of lime, Politis.....	133
Origin and office of oxalate of lime in plants, Politis.....	133
Essential oils as the cause of sap movements, Giglioli.....	133
Formation of alkaloids in tobacco, Ravenna and Babini.....	133
Heliotropism in radium illumination, Molisch.....	134
Investigations on Mucorineæ and their relations to soils, Hagem.....	134
The slime or gum of <i>Rhizobium leguminosarum</i> , Greig-Smith.....	134

## FIELD CROPS.

[Field crops at the Hawaii Station], Kelley, Wilcox, and McClelland.....	135
[Rotation and fertilizer tests], Eustace and Shoemith.....	136
Cooperative grain investigations at McPherson, Kans., 1904-1909, Cory.....	137
Studies of the principal buckwheat species, Miège.....	137
The condition of Kansas seed corn, Schafer.....	138
The seed corn situation, Williams.....	138
Some data for oat growers, Burnett.....	138
Composition of oats as affected by fertilization, hilling, and seeding, Ebert..	139
Rice.—A possible new industry for California, Shaw and Gaumnitz.....	140
Soy beans as a supplementary silage crop, Minns.....	140
Report on field trials with varieties of swedes in 1910, Harrison and Stokes....	141
Adulteration and misbranding of clover, grass, and hairy vetch, Galloway....	141
Seed tests made at the station during 1911, French.....	142
Quality of farm seeds in 1911, Hall.....	142
Methods of keeping crop records at the Michigan Station, Spragg.....	142

## HORTICULTURE.

Report of the horticulturist, Higgins.....	142
Report of the South Haven substation, Wilken.....	143
The horticultural industries in Germany.....	144
List of secretaries of state and other horticultural societies.....	144
The profitable culture of vegetables, Smith.....	144
List of publications important to fruit growers, Stewart.....	144
[Orchard cover crops], Eustace.....	144
Profitable crops for the young orchard, Price.....	144
Methods and implements in orchard cultivation, Surface.....	144
Spraying practice for orchard and garden, Beach.....	144

	Page.
The present status of varieties in commercial orchards, Drinkard, jr. ....	144
Vegetable forcing with special reference to etherization of strawberries, Bultel. .	145
Grape stocks best suited for dry and limy soils, Garcia de los Salmenes. ....	145
Hot room callusing, Bioletti and Bonnet. ....	145
Investigations on the practice of heading-in grapes, Ravaz. ....	145
Grape culture in Pennsylvania, Sill. ....	145
Contribution to the study of olive varieties, Ruby. ....	145
Protecting the California orange crop from frost, McAdie. ....	145
Keeping quality of citrus fruit treated to eliminate frosted fruit, Mann. ....	145
Alcohol for separation of frosted fruit, Lefferts. ....	145
Fruit drying, Allen. ....	146
Morphologic-physiologic investigations of the flowers of coffee, von Faber. ....	146
Coffee culture, Tellez. ....	146
Fertilizer experiments with coffee, Helmrich. ....	146
The coco palm and its culture, Preuss. ....	146
Roses, Darlington. ....	146

Clinical symptoms, prophylaxis, and treatment of distemper, McGowan.....	187
<i>Bacillus bronchicanis</i> , the cause of canine distemper, Ferry.....	187
Contribution to the study of epizootic lymphangitis, Teppaz.....	188
Fernicious anemia (typho-anémie infectieuse) of the horse, Finzi.....	188
Infectious paraplegia of the horse, Moulum and Oyuela.....	188
A report upon the permanent value of the roaring operation, Hobday.....	188

## RURAL ENGINEERING.

On the measurement and division of water, Carpenter.....	188
[The regulation of hydraulic works in the United States], Tavernier.....	188
An experiment station for irrigation, Conti.....	188
Irrigation in Egypt, Barois.....	188
Irrigation and drainage, Wade.....	188
Proceedings of third drainage convention at Wilmington, N. C., 1910, Pratt.....	189
Reclaiming land by drainage, McVeigh.....	189
[Drainage in land reclamation].....	189
[A drainage plan in Louisiana], White.....	189
Drainage, Watson.....	189
Cost and methods of clearing land in western Washington, Thompson.....	189
Highway engineering, Blanchard and Drowne.....	189
Science in the service of highway construction, Richardson.....	190
Good roads, Watson.....	190
Proceedings of second convention of Inter-Mountain Good Roads Association.....	190
Report of the State Highway Commission of Minnesota, 1909-10.....	190
French experiments with tarred roads, Hunt.....	190
Highway bridges and culverts, Hoyt and Burr.....	190
Culvert practice in road building in connection with drainage ditching.....	190
A plan for a small dairy house, Kelly and Parks.....	190
The ventilation of stock stables, Ulrichs.....	190
The development of agricultural machinery in Germany, Fischer et al.....	190
Wood used in construction of agricultural implements, Kramch.....	191
The hand-winch stump and tree puller.....	191
Motor cultivation on a farm, Sagnier.....	191
Examination of a seeding machine for garden or nursery planting, Fruwirth.....	191
Potato-digging machines, Seymour.....	191
A wagon for carrying heavy loads.....	191
New ideas in modern straw balers, Fabricius.....	191

## RURAL ECONOMICS.

Agricultural credit and cooperation in England and Wales.....	191
Cooperative societies.....	192
Agricultural purchase societies in Italy up to 1910.....	192
Importance of the national insurance law to agriculture, Schumacher.....	192
An argument for the short-time lease, Elijah.....	192
Prosperity on a rented farm in Iowa, Nicholson.....	193
Profitableness of agriculture in Argentina, Pfannenschmidt.....	193
High cost of living and agriculture in France, Lair.....	193
Agriculture in Egypt, Cowan.....	193
[Agricultural] production.....	193
Agricultural statistics.....	194
Foreign crops, March, 1912, Daugherty.....	194

## AGRICULTURAL EDUCATION.

	Page.
Education for agriculture, Mumford.....	194
The country school, Focht.....	194
Rules, regulations, and laws relating to high and graded schools.....	194
Teachers' extension schools, Bricker.....	195
The Scottish system of continuation schools, Cooley.....	195
The "Landwirtschaftliche Institut" of the University of Halle, Price.....	195
Reports on agricultural and housekeeping schools for 1910-11.....	195
Agricultural nature study, Palmer.....	195
First annual report of the School Garden Association of America.....	195
Kentucky Arbor and Bird Day, 1911, Reid.....	195
Report of committee on courses of study in agriculture, Bishop.....	196
Spring laboratory methods, Minear.....	196
Potato studies for schools, Hungate.....	196

## MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1911.....	196
Twenty-seventh Annual Report of the Bureau of Animal Industry, 1910.....	196
Annual Report of Hawaii Station, 1911.....	196
Twenty-fourth Annual Report of Michigan Station, 1911.....	196

# EXPERIMENT STATION RECORD.

VOL. XXVII.

AUGUST, 1912.

No. 2.

---

The fifth session of the Graduate School of Agriculture was held at the Michigan Agricultural College, East Lansing, Mich., July 1 to 26. As heretofore, the school was under the general management of the Association of American Agricultural Colleges and Experiment Stations, through its standing committee on graduate study. The financial support of the school was derived from the contributions of many of the colleges represented in the association, the matriculation fees of the students, and the funds of the Michigan Agricultural College. This institution, through its president and trustees, generously assumed responsibility for the maintenance of the school. President Snyder, Secretary Brown, Dean Shaw, and other members of the faculty made the local arrangements for the sessions and otherwise contributed in many ways to its success. The lectures and seminars were largely held in the great Agricultural Building, admirably adapted for the purpose, but the Bacteriological and Entomological buildings were also used. The lecturers were very pleasantly housed in the spacious Woman's Building, where Dean Gilchrist and her associates in the home economics department did much to make their stay at the college very agreeable; other buildings, libraries, and other equipment of the college were placed at the disposal of the school. The extensive field experiments, the botanic garden, and the many varieties of trees on the beautiful campus furnished much of interest for observation. Dr. A. C. True, Director of the Office of Experiment Stations, served as dean, as at the previous sessions, and Secretary A. M. Brown, of the Michigan College, acted as registrar.

Courses of study were offered in the following lines: Soils and plant physiology, animal physiology, agronomy, horticulture, beef and dairy cattle, swine and poultry, rural engineering, and rural economics, including farm management. As at previous sessions, the hours were so arranged that all interested in plants could attend the course in soils and plant physiology, and those interested in animals the course in animal physiology, and these courses dealt more particularly with fundamental topics considered from the standpoint

of both pure and applied science. The other courses were so arranged that the students naturally divided into smaller groups along the lines of their chief special interests.

The faculty numbered forty-eight, in addition to six speakers at special conferences on general questions relating to agricultural education and research. It included seven officers of the U. S. Department of Agriculture, fifteen members of the faculty of the Michigan Agricultural College, and eighteen professors and experts from fourteen other agricultural colleges and experiment stations. In addition, lecture courses and seminars were given by Dr. T. N. Carver, professor of economics of Harvard University; Dr. H. C. Sherman, professor of food chemistry, Columbia University; Dr. L. B. Mendel, professor of physiological chemistry, Yale University; Dr. Oscar Riddle, research associate of the Carnegie Institution of Washington; and H. N. Ogden, professor of sanitary engineering, Cornell University.

Many interesting and valuable matters were also brought out from an international viewpoint in the lectures given by Dr. E. J. Russell, Director of the Rothamsted Experiment Station, England; Dr. F. H. A. Marshall, professor of agricultural physiology, Cambridge University, England; and Dr. Oscar Loew, of the Hygienic Institute, Munich, Germany.

The total enrollment of students at the close of the session was one hundred and eighty, including forty-one women, who were also enrolled in the Graduate School of Home Economics. This latter school was under the general management of the American Home Economics Association, and for the first time prolonged its session to cover four weeks. As heretofore it was conducted in close affiliation with the Graduate School of Agriculture. The students in both schools came from thirty-four States and Porto Rico, Canada, Russia, China, and Japan.

The public opening exercises were held on the evening of July 3 in the auditorium of the Agricultural Building of the college, and were well attended. Dr. H. P. Armsby, chairman of the committee on graduate study of the association, presided and made an introductory address. An address of welcome was made by President Snyder on behalf of the Michigan Agricultural College. Dean R. S. Shaw, of the agricultural division of this college, spoke on the leading features of Michigan agriculture. Dean Maude Gilchrist, of the home economics division, spoke on the work of the Graduate School of Home Economics. Dean True, of the Graduate School of Agriculture, gave a brief summary of the history of the school during the decade of its existence, and pointed out in a general way the development of American agriculture and agricultural education and research during that period. The substance of his remarks on the latter topic are as follows:

The main objects of the school have been to arouse interest in graduate study and to stimulate a keener sense of the needs and requirements of such work by bringing graduate students for a brief time under the direct influence and inspiration of leading teachers and investigators in different branches of agricultural and related sciences. There can be no doubt that this school has exerted considerable influence in promoting the establishment of graduate courses in agriculture in a number of institutions. It is also believed that it has done much toward creating more favorable conditions for serious study and research along agricultural lines in our whole system of agricultural colleges and experiment stations. And through its conferences on pedagogical and other questions relating to the broader aspects of agricultural education it has aided in the wider diffusion of agricultural knowledge through the lower schools and extension agencies.

In the decade during which the Graduate School of Agriculture has been in operation the movement for agricultural education in the United States has been greatly broadened and strengthened. Comparing very briefly the statistics of 1901 with those of 1911 (the latest available), we may get some indication of the growth of our agricultural institutions during this period. The permanent funds and equipment of the land-grant colleges have increased from \$67,000,000 to \$120,000,000 and their income from \$7,000,000 to \$22,000,000. The total number of students has increased from 42,000 to 84,000, and of agricultural students from 7,000 to 16,000.

In 1901, 2,000 farmers' institutes were held in the United States, with an attendance of 500,000; in 1911 there were 6,000 institutes, with an attendance of 2,500,000, to which may be added 1,000,000 persons who attended the lectures given in connection with special railroad trains and other forms of extension work.

Meanwhile there has been a remarkably rapid introduction of agriculture into the secondary schools. Within the past two years the number of institutions of secondary grade giving courses in agriculture has risen from 700 to 2,300.

Within the past ten years experimental and research work in agricultural lines has also greatly increased. In 1901 the experiment stations had an income of \$1,232,000, as compared with \$3,615,000 in 1911; and the membership of their staffs increased from 688 to 1,587. In the middle of this period the Adams Act was passed, which has already done very much to set in operation higher researches on agricultural problems.

It is interesting to note the increase in some lines of research—the number of chemists increasing from 146 to 293; botanists from 49 to 84; mycologists and bacteriologists from 21 to 60; entomologists from 48 to 108; horticulturists from 78 to 131; animal husbandmen

from 14 to 101; and dairymen from 31 to 77. Great advance in specialization is also shown in the following, who did not appear at all in the 1901 statistics of the stations but were given in 1911: Agronomists 139; plant breeders 12; soil specialists 34; plant pathologists 54; foresters 22; poultrymen 32; and agricultural engineers 21.

Meanwhile the financial interests involved in American agriculture have grown enormously. Land values have more than doubled and aggregate nearly thirty billions of dollars; total values of farm property have also doubled and aggregate over forty billions of dollars. The total value of the agricultural products of the United States for the twelve years ending in 1910 was seventy-nine billions of dollars.

The number of our farms has increased only ten and five-tenths per cent, but they aggregate 6,340,000; the farm population has increased very slowly, but there are thirty million people on our farms.

We are just awakening to the vast significance of the human and material problems involved in the development of our agriculture. Attention is just now focused on the rapid spread of the movement for popular education in agriculture. But those who stand closest to this great movement and realize most fully what it means, know also that there never was a time when wise leadership and sound and deep knowledge in agricultural matters were so much to be desired as to-day. The period of propaganda to convince the rural people of the desirability of agricultural education and research is nearly over. What is especially needed now is wise and well-educated leadership in order that the great movement under way may be efficiently organized and guided in right channels. Thoroughly trained investigators, teachers, and administrators are needed in constantly increasing numbers, and the supply is far below the demand. The importance of such conferences along the higher ranges of agricultural work as this Graduate School is greater than ever before and we ought to pursue our work here with the greatest enthusiasm and seriousness, in the hope that our meeting together will help to strengthen the forces which are seeking to guide public sentiment in right channels of thought and activity for agricultural advancement and to disseminate useful and sound knowledge on agricultural subjects among great numbers of students in our agricultural institutions and among the masses of our rural people throughout the United States.

The courses in soils and plant pathology, animal physiology, and rural economics, including farm management, were very strong and attractive. The problems of the soil were discussed in their physical, chemical, and biological aspects and from many points of view. Dr. Schreiner, of the Bureau of Soils, discussed the organic soil

constituents and their effect on plant growth, and summarized his own recent investigations on the biochemistry of soils. Professor Patten, of the Michigan Agricultural College, presented the chemical status of soil phosphorus, and his associate, Mr. Robinson, discussed the chemistry of humus. Dr. Headden, of the Colorado Agricultural College, described the peculiar characteristics of Colorado soils and gave the results of his investigations on the problems of alkali and nitrates in those soils; Dr. E. J. Russell treated the production of plant food in the soil, with special reference to the Rothamsted investigations on the effect of partial sterilization on the soil organisms. Professor Jeffery, of the Michigan College, discussed various factors affecting the functioning of soils, and his associate, Dr. Bouyoucos, showed the radiating power of soils under various conditions. Dr. Bizzell, of Cornell University, presented some of the results of investigations by Dr. Lyon and himself on the problems of nitrification and the colloidal matter in soils; Dr. Duggar, of the same institution, dealt with the rôles of mineral nutrients in plant metabolism and the fixation of nitrogen by soil organisms. Dr. Oscar Loew, of the Hygienic Institute, Munich, Germany, discussed the rôle of mineral nutrients in animals and plants, especially in regard to lime and magnesia.

In the course in animal physiology, Dr. Mendel discussed some of the problems in the biochemistry of nutrition, and summarized the newer researches on nutrition in growth and maintenance; Dr. Sherman treated the functions of food and of the digestive ferments and the utilization of specific food materials; and Dr. Forbes, of the Ohio Experiment Station, dealt with the mineral elements in animal nutrition. Dr. C. E. Marshall, of the Michigan Agricultural College, and his associates, Messrs. Brown, Giltner, Rahn, and Van Suchtelen, discussed the biology of the cell. Dr. Riddle's lecture had to do with the phenomena of development, with special reference to color characters and the physiological basis of sex. The significance and origin of sex differentiation and the inheritance of sex were discussed by Dr. Pearl, of the Maine Experiment Station. Mr. Morse, of this Office, dwelt especially on the importance of the application of physiological methods to live stock investigations and instruction.

In rural economics, Dr. Carver laid special stress on the economizing of human energy and of land in the rural industries, and the general problems connected with the maintenance of the efficiency of the rural population. Mr. Galpin, of Wisconsin University, emphasized the social factors of the rural community; Dr. Hedrick, of the Michigan College, spoke on human ecology; Dr. Warren, of Cornell University, described the methods of making agricultural

surveys, and gave many interesting illustrations drawn from his work in New York with reference to the size and character of farms as related to their productiveness and financial returns. Messrs. C. B. Smith and E. H. Thomson, of the Farm Management Division of the Bureau of Plant Industry, described the methods pursued in farm management field studies and demonstrations, and discussed farm organization and labor and the factors affecting profits in farming in the corn belt.

In the course in rural engineering, lectures were given on drainage by Professor Stewart of Minnesota, roads by Dr. Hewes of the Office of Public Roads, irrigation in humid regions by Mr. Williams of this Office, rural sanitation by Professor Ogden of Cornell University, and farm mechanics by Professor Davidson of Iowa State College. During the last week of this course important conferences on the scope and methods of instruction in rural engineering in the agricultural colleges were held by a number of the heads of such departments in different institutions.

Eight interesting conferences on the principles of general and agricultural research, the scope, aim, and methods of college and secondary instruction in agriculture and of extension work along this line were held under the leadership of Dean Hunt of Pennsylvania State College, Professor Coulter of the University of Chicago, Dean Russell of the Wisconsin College of Agriculture, Professor Tuck of the New York State College of Agriculture, Professor Christie of Purdue University, Professor French of Michigan Agricultural College, and Dean True.

Meetings of the International Association of Poultry Instructors and Investigators, the Association of Official Dairy Instructors, and the American Society of Agronomy were held before or during the session of the Graduate School of Agriculture, as well as the annual conclave of the Alpha Zeta Fraternity. Excursions were made to peppermint and other farms in the vicinity of Lansing. Receptions to the school were given by President and Mrs. Snyder at their home, and by Dean Gilchrist at the Woman's Building.

Much high-grade work was done at this session of the Graduate School of Agriculture, and the discussions covered a wide range. It is believed that the three hundred persons who came in contact with this school as lecturers, students, or visitors gave and received much of value as inspiration to better teaching and investigating, and that the results of this session will be widely felt in our agricultural institutions.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Handbook of biochemical methods**, edited by E. ABERHALDEN (*Handbuch der Biochemischen Arbeitsmethoden*, Berlin and Vienna, 1912, vol. 5, pt. 2, pp. XV+673-1467, pl. 1, figs. 139).—This portion of the work deals with the detection of poisons by chemical methods, the transplantation of tissues, the technique of cultivating tissues in vitro, methods for the biochemical examination of the soil, methods for metabolism tests with micro-organisms, the gasometric determination of primary aliphatic amino-nitrogen and its use for physiological-chemical investigations, the analysis of proteins for determining the characteristic groups of various amino acids, the Zuntz method of gas analysis, new apparatus for metabolism experiments, ash analysis, ultra-filtration, tables for the preparation of solutions with definite hydrogen ion concentrations, methods for biological micro-analysis, methods for studying intermediary metabolism, methods for the biochemical study of plants, quantitative micro-elementary analysis of organic substances, capillary analysis, biochemical and chemotherapeutic methods for trypanosomes, and reagents for detecting the more important biological compounds.

**An introduction to the chemistry of colloids**, V. POSCHL, trans. by H. H. HODGSON (London, 1910, pp. 114).—An English edition of the German work previously noted (E. S. R., 24, p. 120).

**Introduction to colloid chemistry**, V. POSCHL (*Einführung in die Kolloidchemie*, Dresden, 1911, 3. ed. rev., pp. 89).—A third edition of the work above referred to.

**Physical chemistry of the cell and tissue**, R. HÖBER (*Physikalische Chemie der Zelle und der Gewebe*, Leipzig, 1911, 3. ed., pp. XV+671, figs. 55; rev. in *Biol. Centbl.*, 32 (1912), No. 4, pp. 243-250).—A third revised and enlarged edition of this work on physical chemistry as applied to physiological problems.

**Chemistry of the cell**, W. J. GIES ET AL. (*Biochem. Bul.*, 1 (1911), No. 1, pp. 65-93).—These are abstracts of communications to a symposium on the chemistry of the cell, held at Columbia University, including intracellular water, salins, carbohydrates, lipins, proteins, extractives, and enzymes, and factors in immunity.

**In regard to the chemistry of chlorophyll**, M. S. TSVETT (*Rev. Gén. Sci.*, 23 (1912), No. 4, pp. 141-148).—This article gives a general view of the present status of the chemistry of chlorophyll.

**Yearbook of chemistry**, edited by R. MEYER (*Jahrb. Chem.*, 20 (1910), pp. XII+568).—This is a report of the more important progress made in the field of pure and applied chemistry for the year 1910.

**Investigations in regard to the precipitation of proteins**, A. J. J. VANDELVELDE (*Bul. Soc. Chim. Belg.*, 25 (1911), No. 4, pp. 166-173).—Continuing previous work (E. S. R., 25, p. 709), the author now reports further results of

experiments in precipitating fractionally by various methods proteins from cow's milk, colostrum, equine and bovine serum, and hen's eggs. Some proteins were redissolved and precipitated.

The results bring out the fact that the transformation of one protein into another is not uncommon, and furthermore that the transformations which do occur include changes in regard to their precipitation with reagents and temperature of coagulation.

The synthesis of fats by the action of enzymes, F. L. DUNLAP and L. O. GILBERT (*Jour. Amer. Chem. Soc.*, 33 (1911), No. 11, pp. 1787-1791).—Previously noted from another source (E. S. R., 26, p. 307).

The variations in the phosphorus content of seeds under varying vegetative conditions, MILLE S. LEWONIEWSKA (*Bul. Internat. Acad. Sci. Cracovie. Cl. Sci. Math. et Nat., Ser. B.* 1911, No. 2, pp. 85-96).—The variation in the total phosphorus and nitrogen content of oat seeds was found to be due chiefly to the vegetative conditions, and the variety of seed employed had practically no relation to these constituents. The greatest variation was in the case of the phosphorus compounds soluble in 1 per cent acetic acid solution, namely, inorganic phosphorus and phytin, with little variation for protein and lecithin phosphorus.

Plants which received a goodly supply of phosphorus showed 2, 3, and 4 times more inorganic and phytin phosphorus than those which received phosphorus sparingly. From this it follows that plants receiving scant amounts of phosphorus will yield seeds which have appropriated much of the phosphorus for the production of nuclein compounds, while those plants having a good supply of phosphorus to draw upon will show a larger storage of phosphorus as inorganic combinations and phytin in the mature seed. The variation in the nitrogen content of the seeds was far greater than that of the phosphorus, and the protein nitrogen showed a greater fluctuation than the nonprotein nitrogen. The reason for this variation was not apparent to the author. It is believed that by determining in the seed the phosphorus soluble in 1 per cent acetic acid a better index can be obtained as to the assimilable phosphorus in the soil than by determining the nitrogen-phosphorus ratio of the seed.

In regard to the action of phosphates upon the activity of proteolytic ferments, N. N. IWANOW (*Trudy Imp. S. Peterb. Obshch. Estestvo. (Trav. Soc. Imp. Nat. St. Petersb.)*, 42 (1911), III, No. 2-8, pp. 225-238).—It was found that potassium acid phosphate ( $KH_2PO_4$ ) accelerates the autolysis of proteins in yeast extract (hefanol). This activity was found to increase to a certain point when the phosphate content was increased (from 0.38 to 1.52 per cent), and was dependent upon the temperature and the amount of protein present, but independent of a preexisting fermentation of saccharose. In all instances it was found that no total solution of the protein took place, and only 16 per cent dissolved when 1.52 per cent of phosphate was present. In water, as well as in a 5 per cent saccharose solution, the cleavage was accelerated by neutral phosphates at various temperatures, but the action was retarded by alkaline phosphates ( $K_2HPO_4$ ).

Some observations upon the assay of digestive ferments, H. T. GRABER (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 12, pp. 919-921).—The results show "that the composition of the white of the egg, chemically and probably even physically, when used for the assay of pepsin, has a great bearing upon the apparent strength of this ferment. The albumin seems to be more difficult to digest the first 24 hours after the egg is laid and a change gradually takes place until after about 5 to 7 days it has reached its maximum solvent condition. After this period its digestibility gradually diminishes.

“In the assay of pancreatin for starch hydrolysis, as well as all the diastasic ferments, the kind of starch used is of prime importance and in stating the strength of each it should be in terms of the particular starch employed.”

In tests with papain it was found to make very little difference what kind of raw beef was used when the ferment was acting in acid media, but if the nature of the beef was changed (for instance, by cooking) papain was found to lose its solvent action. Rennet was found to be influenced in its coagulating power by the chemical composition of the milk as regards the presence and amount of inorganic salts, particularly calcium salts. The mixing of the rennet with the milk, the temperature at which the milk was kept before and during the test, and finally the breed of cows from which the milk was obtained were additional factors.

**Action of the salts of the gold group upon the saccharification of starch by amyolytic ferments.** C. GERBER (*Compt. Rend. Soc. Biol. [Paris]*, 70 (1911), No. 13, pp. 547-553).—This is a continuation of the studies previously noted (E. S. R., 25, p. 107) with the salts of this group as to the hydrolysis of starch. Zinc chlorid acidulated with hydrochloric acid, potassium oxalate acidulated with oxalic acid, copper chlorid, and the various chlorids of gold and platinum were employed. Some tests upon the coagulation of milk with these chemicals are also included.

**Action of the salts of the alkali metals upon the saccharification of starch by amyolytic ferments.** C. GERBER (*Compt. Rend. Soc. Biol. [Paris]*, 70 (1911), No. 10, pp. 391-397).—The author reports his results with the salts from inorganic, monobasic acids (chlorids, nitrates, and fluorids of sodium, potassium, and ammonium), the salts of dibasic acids (sodium sulphate and bisulphate), and those from tribasic acids (tri-, di-, and monopotassium orthophosphates). Experiments were also made with the organic salts of monobasic organic acids from the aliphatic and aromatic series (sodium formate, acetate, butyrate, propionate, valerate, stearate, palmitate, benzoate, and salicylate), and salts of the polybasic acids (potassium and sodium oxalate and citrate).

**Action of some salts upon the saccharification of Fernbach and Wolff's soluble starch by amyolytic ferments.** C. GERBER (*Compt. Rend. Soc. Biol. [Paris]*, 71 (1911), No. 27, pp. 247-249).—This work was done with the chlorids of cadmium, bichlorid of mercury, zinc chlorid, cupric chlorid, silver nitrate, potassium oxalate, sodium citrate, and quinin hydrochlorate.

In regard to catalase, GRIMMER (*Milchw. Zentbl.*, 7 (1911), No. 7, pp. 314-316).—A discussion in regard to the findings of W. D. Kooper (E. S. R., 26, p. 112) with the various forms of apparatus for determining the catalytic activity of milk.

**The examination of substances important in agriculture and the industries.** J. KÖNIG (*Die Untersuchung landwirtschaftlich und gewerblich wichtiger Stoffe*. Berlin, 1911, 4. ed. rev., pp. XX+1226, figs. 426).—This is the fourth edition of this work (E. S. R., 17, p. 1133).

**A quantitative method for determining small amounts of potassium.** E. A. MITSCHERLICH, K. CELICHOWSKI, and H. FISCHER (*Landw. Vers. Stat.*, 76 (1912), No. 1-2, pp. 139-155).—The method which follows is recommended for determining small amounts of potassium in soil extracts which are obtained by extracting soil with water, saturated with carbon dioxid, and any other material containing potassium.

To 250 cc. of the soil solution in a beaker, 5 cc. of concentrated nitric acid and 5 drops of dilute (1:3) sulphuric acid are added, and the whole concentrated to a bulk of 20 cc. The concentrated solution is transferred quantitatively to a platinum or quartz dish, evaporated to dryness, and the organic matter destroyed by heating the dish for a short time.

The residue is taken up with 1 drop of a concentrated sodium carbonate solution, free from potassium, and a few cubic centimeters of warm water. The solution is evaporated and the residue heated until fusion of the sodium carbonate has taken place. The cooled residue is approximately neutralized with nitric acid, and any free acid which remains must be removed by evaporation. The residue from this is then dissolved in about 5 cc. of hot water and treated with 3 cc. of a 10 per cent cobalt chlorid solution and about 5 cc. of a 10 per cent sodium nitrite solution. After this the solution is evaporated to dryness slowly (shaking occasionally during the process to avoid crust formation) at a temperature of from 80 to 90° C., and when cooled 3 cc. of a 10 per cent acetic acid is added to dissolve the excess of sodium cobaltic nitrite.

On solution of the crust 10 cc. of water is added, and the crystalline residue which remains is transferred to a Gooch crucible which holds a disc of hardened filter paper. The precipitate on the filter is washed with small amounts of a 2½ per cent solution of sodium sulphate. To the crucible and washed residue contained in a beaker about 20 cc. of fiftieth-normal potassium permanganate and 100 cc. of water are added, and the beaker and its contents is placed in a water bath, the temperature of which is then gradually raised to the boiling point. The beaker is shaken occasionally during the interim. If manganese superoxid separates out, 25 cc. of dilute sulphuric acid is added drop-wise. When the yellow precipitate on the filter has dissolved the beaker is removed from the water bath and an excess of fiftieth-normal oxalic acid solution is added, and the excess of oxalic acid is titrated with fiftieth-normal potassium permanganate solution (1 cc.=0.0001571 gm. of potassium oxid).

This method can also be used for examining material containing large quantities of potassium.

An improved Hollemann method for estimating phosphoric acid, E. VITORIA (*Chem. Ztg.*, 35 (1911), No. 123, p. 1152; *abs. in Analyst*, 36 (1911), No. 429, p. 695).—"When a superphosphate is boiled for a few hours in a cold saturated solution of ammonium nitrate, almost the whole of the phosphoric acid goes into solution. About 2 gm. of the superphosphate, finely ground and dried at 115 to 126° C., are vigorously boiled for about 10 hours with 100 to 150 cc. of ammonium nitrate solution, 10 cc. of sodium acetate solution, and 500 cc. of water; the water lost by evaporation is replaced from time to time, and the liquid is finally made up to 1 liter. Forty cc. of this solution are made slightly alkaline with sodium hydroxid and shaken with 20 cc. of tenth-normal silver nitrate solution; the silver phosphate is filtered off rapidly, and the excess of silver in the filtrate is titrated according to Volhard's method."

Neutral ammonium citrate solutions, A. J. PATTEN and C. S. ROBINSON (*Michigan Sta. Rpt.* 1911, pp. 173-178, figs. 2).—The work here reported has been previously noted (E. S. R., 26, p. 98). See also an article by Hall (E. S. R., 26, p. 109).

The use of Busch's "nitron" for the determination of nitrate nitrogen in soils and fertilizers, C. S. ROBINSON and O. B. WINTER (*Michigan Sta. Rpt.* 1911, pp. 178-181).—The authors conclude that "the 'nitron' method [E. S. R., 16, p. 945] seems to be generally inapplicable to the determination of nitrate nitrogen in soils but can be used to advantage in the determination of this form of nitrogen in fertilizers. The reason for its failure in the case of soils is the presence of organic matter which either contaminates the precipitate or holds it up."

Practical hints for determining the hygroscopicity of soils by the Rodewald-Mitscherlich method, G. VON ROMBERG (*Landw. Vers. Stat.*, 75 (1911), No. 5-6, pp. 483, 484).—This deals with some points in regard to the evacua-

tion and influx of air during the desiccation of soils with the aid of phosphorus pentachlorid.

A simple method for determining the mineral substances in water and another for estimating the hardness of drinking and industrial waters, WUNDER (*München. Med. Wchuschr.*, 58 (1911), No. 49, pp. 2611-2613, fig. 1).—The method consists in measuring in milliamperes the amount of a constant current passing through a definite amount of water. The figure obtained is a definite index to the amount of mineral substance present. The hardness of the waters is determined by a solution of lysol, a soapy emulsion of cresols.

A simple method for detecting and estimating the nitrites and nitrates in water, J. TILLMANS and W. SUTTHOFF (*Ztschr. Analyt. Chem.*, 50 (1911), No. 8, pp. 473-475).—The chief advantages of this modified method for determining nitrates and nitrites with diphenylamin-sulphuric acid (E. S. R., 25, p. 14) are as follows: (a) The rapidity and simplicity with which the method can be carried out, because it requires no special form of apparatus; (b) only a few cubic centimeters of water are necessary for the test, even when small amounts of nitrites or nitrates are present. One-tenth mg. of nitrous and nitric acids per liter can be determined with accuracy.

A rapid preliminary test for detecting added water to milk, J. TILLMANS (*Molk. Ztg. Berlin*, 22 (1912), No. 4, pp. 39, 40; *Chem. Ztg.*, 36 (1912), No. 10, p. 81).—The author calls attention to the value of the diphenylamin-sulphuric acid reagent for detecting added water in milk.

The determination of saccharose and the detection of dextrin in some food products, A. F. VOLLANT (*Ann. Falsif.*, 4 (1911), No. 36, pp. 504-509).—Lemeland's method (E. S. R., 24, p. 611) can be used for commercial sugars, sirups, comfits, dried milk, and honey. As dextrin is not attacked to any great extent by this procedure, the method can be employed with the aid of the polariscope for detecting this substance in foods.

Constants of chicken and turkey fats, R. ROSS and J. RACE (*Analyst*, 36 (1911), No. 422, p. 213).—A number of constants are given, as follows:

*Constants for fat and fatty acids of chicken and turkey fat.*

Constants.	Fat.		Fatty acids.	
	Chicken.	Turkey.	Chicken.	Turkey.
Specific gravity at 100° F. ....	0.9065	0.9090	0.8866	0.8990
Koettstorfer value. ....	204.6	191.6	208.3	195.0
Molecular weight. ....			270.0	287.0
Iodin value (Wijs).....	71.5	66.4	73.6	70.7
Reichert-Meißl value.....	1.8	3.8		
Polenske number.....	2.1	1.6		
Acetyl value.....			25.4	18.4
Ricinoleic acid, per cent.....			13.7	9.9
Hehner value.....	94.6	95.1		
Melting point, ° C.....	23 to 27	31 to 32	27 to 30	37 to 38
Zeiss number at 50° C.....	47.5	46.0	36.5	32.5

"The fats were optically inactive. An examination of the fat from fowls which had died of overfeeding invariably showed a higher Zeiss number and iodine value than the normal values given above. This result is generally brought about by the use of too much heating food."

Determination of gliadin or alcohol-soluble protein in wheat flour, R. HOAGLAND (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 11, pp. 838-842).—The chief differences in the methods used for the determination of gliadin in wheat flour lie in the strength of the alcohol employed and in methods of extraction.

It was found in this work that alcohol of the strength of 45 to 55 per cent by weight will extract all the alcohol-soluble nitrogen, or gliadin, present in wheat flour. A 75 per cent solution (by weight) of alcohol will extract the same amount of protein as distilled water.

Much confusion exists in the literature as to whether the amount of alcohol usually recommended is 70 per cent by weight or volume. If considered on the basis of volume this is equivalent to practically 62.5 per cent by weight.

The method used by the author is as follows: "Weigh approximately 2 gm. of flour into an 8-oz. milk sterilizer bottle, add 100 cc. neutral 50 per cent by weight alcohol; shake in machine for 1 hour, centrifuge for 10 minutes, filter, determine nitrogen in aliquot portion of filtrate by modified Kjeldahl method. Correction is always made for a blank determination run with alcohol, etc. In using a shaking machine it is, of course, necessary to have the bottles shaken vigorously so that the flour will remain in suspension. The use of the centrifuge makes filtration easy, which would otherwise be rather slow, due to fine flour particles in suspension."

The testing of the quality of gliadin in flour, J. APSIT and BROcq-ROUSSEU (*Ann. Sci. Agron.*, 3. ser., 6 (1911), II, No. 2, pp. 81-86, figs. 2).—A description of an apparatus for determining the quality of the gliadin in wheat flour, and which is said to have none of the disadvantages of the Boland and other apparatuses used for this purpose.

In regard to the acids in honey, A. HEIDUSCHKA (*Chem. Ztg.*, 35 (1911), No. 118, pp. 1104, 1105).—This is a continuation of the work previously reported (E. S. R., 26, p. 25), and includes determinations of the total acidity, total volatile acids, formic acid according to the mercurous-chlorid and carbon monoxid methods, and lactic, malic, and phosphoric acids. Citric and succinic acids could not be detected with certainty. Free acids from the wax or higher fatty acids were noted.

The differentiation of almonds from similar seeds, E. HANNIG (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 21 (1911), No. 10, pp. 577-586, figs. 9).—A description of the histological characteristics of almonds, and of peach, plum, apricot, and similar stones.

Determination of malic acid, P. B. DUNBAR and R. F. BACON (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 11, pp. 826-831).—This has been previously noted from another source (E. S. R., 25, p. 715).

The immersion refractometer as a rapid means of approximating the solids in vinegar, R. E. REMINGTON (*North Dakota Sta. Spec. Bul.*, 2 (1912), No. 3, pp. 40, 41).—Immersion refractometer readings were taken on a series of commercial vinegars, using the undiluted vinegar and at a temperature of 17.5° C. The amount of volatile acid, as acetic acid, was also determined, and the reading for acetic acid solution of this strength, calculated from Wagner's table, subtracted from the reading obtained on the original vinegar. The resulting difference was supposed to be due to the amount of solids present, and an attempt was made to determine this relationship.

The results obtained failed to disclose any marked peculiarity in the solids of cider vinegar, but the author is of the opinion from the abnormalities shown that a large number of determinations on authentic samples of cider vinegar may yield a factor characteristic of this substance.

A method for the detection of small quantities of coumarin, particularly in factitious vanilla extracts, H. J. WICHMANN (*U. S. Dept. Agr., Bur. Chem. Circ.* 95, pp. 2).—The method which is proposed is based on the principle that when fused with potassium hydroxid vanillin will yield the potassium salt of protocatechuic acid, and coumarin will yield potassium salicylate. The method is as follows:

"Slightly acidify 25 cc. of the extract, if alkaline, with sulphuric acid, add 25 cc. of water, and distill to dryness. To the distillate, containing the vanilla and coumarin, add 15 to 20 drops of 1:1 potassium hydroxid, hastily evaporate the distillate to 5 cc., and transfer to a test tube. Heat the test tube over a free flame until the water completely evaporates and the residue fuses to a colorless, or nearly colorless mass. The reaction previously described will have occurred. Cool the melt and dissolve in a few cubic centimeters of water. Transfer the solution to a 50 cc. Erlenmeyer flask and acidify slightly with 25 per cent sulphuric acid. The amount of solution should not be over 10 cc. Finally distill the solution into a test tube containing 4 or 5 drops of neutral 0.5 per cent ferric sulphate or ferric chlorid. If coumarin is present in the original extract, an amethyst or purplish color will develop, the intensity being directly proportional to the amount of coumarin present.

"Vanillin and other normal constituents of vanilla extract do not interfere with the method."

The estimation of furfural by means of Fehling's solution, L. EYXON and J. H. LANE (*Analyst*, 37 (1912), No. 431, pp. 41-46).—A series of experiments was conducted with Flohil's method, previously noted (*E. S. R.*, 25, p. 108), to determine the influence of various concentrations, both of furfural and sodium chlorid, and to ascertain the degree of accuracy of the method.

It was found, contrary to the statement of Flohil, that the copper-reducing power of furfural is not independent of the concentration, and therefore there appears no ground for the assumption that a simple stoichiometric relation between the furfural and copper exists. The method yielded good results when corrections for concentration were applied, but in a few instances the error was from 3 to 5 per cent. Flohil's statement that the unreduced copper in the liquid after boiling may be determined by Schoor's iodometric method was confirmed.

Examination of certain milk testing apparatus, II. TIEMANN (*Molk. Ztg. [Hildesheim]*, 25 (1911), Nos. 32, pp. 591, 592; 33, pp. 605-608).—The forms of apparatus tested in this work were the optical butyrometer and the catalase tube of Lobeck (*E. S. R.*, 23, p. 13), the Gloria centrifuge, the neu-sal apparatus, and an automatic pipette for measuring off alcohol. All of this apparatus is in use in Germany.

The determination of the acidity of milk, O. RAMMSTEDT (*Chem. Ztg.*, 35 (1911), No. 131, pp. 1218, 1219; *abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 9, p. 436).—This should be done on the basis of the Soxhlet-Henkel criterions, both on account of uniformity and exactness.

The methods for determining fat most frequently used in milk chemistry, O. VON SOBBE (*Molk. Ztg. [Hildesheim]*, 25 (1911), Nos. 45, pp. 849, 850; 46, pp. 863, 864; 47, pp. 887, 888; 48, pp. 903, 904).—The methods described are the Wollay refractometric, Gottlieb-Röse, Soxhlet specific gravity (areometric), acid butyrometric of Gerber, sal, "neu-sal," Sichler's sin-acid, and Hammer-schmidt's precipitation methods.

Do volatile fatty acids occur in fresh whole milk? W. D. KOOPER (*Milchw. Zentbl.*, 7 (1911), No. 7, pp. 312-314).—According to the author, no volatile fatty acids occur in pure fresh butter fat, and according to this it would naturally be expected that none would occur in fresh milk. He finds, however, that by distilling with steam fresh milk which contains an addition of a little phosphoric acid a distillate containing fatty acids consisting chiefly of butyric acid is obtained. Skim milk with very little fat was found to yield a higher percentage of acid than the distillate from cream. The original acidity of milk also had some influence upon the final results.

A simple method for detecting butter which was prepared from heated cream, HESSE (*Milchw. Zentbl.*, 7 (1911), No. 3, pp. 133-134).—The author has previously reported on a study of the Rothenfusser method (E. S. R., 24, p. 612), as applied to the detection of butter which has been prepared from cream heated to 80° C. or over. The method has now been simplified for the purpose of rendering its use possible by the unskilled, and is as follows: To 10 gm. of butter contained in a Gerber butyrometer, placed in a water bath or drying oven at 40 to 50° C., are added 10 cc. of warm water (40° C.), 2 drops of a 3 per cent hydrogen peroxid solution, and a few drops of Rothenfusser's guaiacol-paraphenyldiamin solution. The butyrometer is stoppered with a rubber, shaken, and centrifuged for 1 minute. If raw cream was used for making the butter the supernatant layer of the fluid will be colored blue.

Examination of crude and refined milk sugar, A. BURR and F. M. BERBERICH (*Molk. Ztg. [Hildesheim]*, 25 (1911), Nos. 76, pp. 1437-1439; 77, pp. 1461, 1462; 78, pp. 1477-1479).—This article has been previously noted (E. S. R., 26, p. 313).

The electrical conductivity of impure sugar solutions, and its relation to the specific gravity and sugar content, W. TAEGENER (*Dent. Zuckerindus.*, 36 (1911), No. 14, pp. 262-264, fig. 1; *abs. in Ztschr. Angew. Chem.*, 24 (1911), No. 28, p. 1338).—As the author was not able to conduct experiments in factories, he prepared fresh press juices instead of diffusion juices. He specifically points out that these investigations are to be considered preliminary tests. It was noted that a relation does exist between the electrical conductivity, specific gravity, and the sugar content of impure sugar solutions.

The unification of reducing sugar methods.—A correction, P. H. WALKER (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 2, pp. 292-299).—Previously noted from another source (E. S. R., 26, p. 312).

A measurement of the translucency of papers, C. F. SAMMET (*U. S. Dept. Agr., Bur. Chem. Circ.* 96, pp. 3).—A practical procedure is described for measuring the translucency of papers. It is free from the objections usually contained in other methods, and can be used for white as well as colored papers. The results are expressed in terms of a standard which is described.

Change in the acid content of distilled vinegar stored in wooden casks, A. BEHRE (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 22 (1911), No. 9, pp. 506-509; *abs. in Analyst*, 37 (1912), No. 430, pp. 23, 24).—Vinegar stored in wooden casks for a period of 9 months increased in acidity from 7.1 to 9.2 per cent, and in total solids from 0.3 to 0.39 per cent. The concentration of these constituents was in all probability due to the more rapid diffusion of the water through the pores of the wood.

"Further experiments were made in which acetic acid solutions of various strengths were exposed to the atmosphere in glass vessels. In glass cylinders solutions containing from 7.44 to 61.2 per cent of acetic acid scarcely altered in strength during 10 weeks, but when exposed in flasks having narrow necks the more concentrated solutions remained unaltered while those containing less than 19 per cent of acetic acid increased in strength to a slight extent. Considerable changes took place when the solutions were exposed in open beakers; the stronger solutions lost large quantities of acetic acid, while the weaker solutions became stronger. Under these conditions, a vinegar containing 3.17 per cent of acetic acid was found to have 4.68 per cent after the lapse of 4 weeks; a solution containing 19 per cent of acetic acid did not alter in strength; while a solution containing 61.2 per cent lost 2.2 per cent of acetic acid during this period."

Milk sugar, A. BURR and F. M. BERBERICH (*Molk. Ztg. [Hildesheim]*, 25 (1911), Nos. 70, pp. 1323-1327; 71, pp. 1347, 1348; 72, pp. 1361-1363; 73, pp.

1385, 1386, figs. 5).—This is a consideration of the development of the milk sugar industry of the world, the use of milk sugar, the methods of obtaining and refining milk sugar, the machinery required therefor, the by-products of milk sugar manufacture, and analyses of the ash of milk sugar and its by-products.

The oil of Douglas fir; a preliminary study of its composition and properties, H. K. BENSON and M. DARRIN (*Jour. Indus. and Engin. Chem.*, 3 (1911), No. 11, pp. 818-820).—The conclusion drawn from these tests is that not less than one-third of fir oil consists of terpineol and that fir oil is so closely similar to pine oil in its properties that it may be substituted for it in its commercial application. It is pointed out that pine oil is being used very extensively as a solvent for varnish gums in the cold, for rubber, for nitrocellulose lacquer, in the manufacture of metal polishes, and for general use as an essential oil, and that this market should be open in the future to fir oil.

### METEOROLOGY—WATER.

A new service of agricultural meteorology in France, P. KLEIN (*Vie Agr. et Rurale*, 1912, No. 7, pp. 169, 170; *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases*, 3 (1912), No. 3, pp. 607-609).—The service which is now being established in France is described. This service will collaborate with the general meteorological service established in 1885. The new service will be directed by a central committee assisted by technical experts.

District stations will be centrally located in regions having similar meteorological conditions and will as far as possible be attached to scientific institutions, such as observatories and schools of agriculture already existing. These will act as centers for the distribution of forecasts and other meteorological information of regional importance, as well as for the collection of data which may be of importance to the central office.

There will be numerous information and warning stations, also connected where possible with local agricultural institutions. These will receive from the regional stations and give out daily telegraphic reports and other information concerning the principal weather conditions and advice regarding means of protection against unfavorable conditions (storms, frosts, etc.). They will in addition give particular attention to the study of the effect of varying climatic factors on the development of plants and their parasites.

Daily observations in agricultural as well as in pure meteorology will be made at a large number of so-called agricultural posts attached both to the district stations and to the information and warning stations.

Monthly Weather Review (*Mo. Weather Rev.*, 39 (1911), No. 12, pp. 1794-1949, pls. 10).—In addition to the usual climatological summaries, weather forecasts and warnings for December, 1911, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology, a condensed climatological summary, and climatological tables and charts, this number contains the following special papers:

December, 1911, Lake Levels; [Meteorological] Summary of Year 1911 [in the Lake Region]; Two Years of Low Water in the Arkansas River, by H. F. Alcatorre; Notes on the Rivers of the Sacramento and San Joaquin Valleys for December, 1911, by N. R. Taylor; Note on Weather Conditions in the San Joaquin Valley for December, 1911, by W. E. Bonnett; Protecting the California Orange Crop from Frost, by A. G. McAdie (see p. 141); and Notes on Frost at San Diego During December, 1911, by F. A. Carpenter.

Meteorological observations, A. J. PATTEN and D. A. SEELEY (*Ann. Rpt. Bd. Agr. Mich.*, 1911, pp. 113-126).—Tabulated daily and monthly summaries are

given of observations during 1910 at East Lansing, Mich., on temperature, pressure, precipitation, cloudiness, wind movement, etc.

**The climate of Prince George's County, W. H. ALEXANDER** (In *The Physical Features of Prince George's County*. Baltimore: Md. Geol. Survey, 1911, pp. 185-206, fig. 1).—The available data regarding temperature and precipitation are summarized. The average annual temperature is 54° F., the annual precipitation 42 in.

**Cold air drainage, F. SHREVE** (*Plant World*, 15 (1912), No. 5, pp. 110-115, fig. 1).—Temperature observations on and near the flood plain of the Santa Cruz River, and at different elevations (ridge and canyon) in the Santa Catalina Mountains up to 8,000 ft., indicated the flow of a shallow stream of cold air down the canyon, constituting an important factor in the limitation of the upward distribution of desert species of plants. "A number of the most conspicuous desert species range to much higher altitudes on ridges and the higher slopes of canyons than they do in the bottoms and lower slopes of canyons. Samples secured by the writer indicate that there is no essential difference between the soil moisture of ridges and the bottoms of canyons during the driest portions of the year. Neither is there any evidence that desert species would fail to survive in the canyon bottoms if they were somewhat higher in soil moisture content. An explanation of the absence of the desert species from canyon bottoms and their occurrence at higher elevations on ridges must be sought in some operation of the chimerical factors rather than in the factors of soil and atmospheric moisture."

**The relation between the amount of rainfall and of seepage, LUEDECKE** (*Separate from Kulturtechniker* [Breslau], pp. 17, pls. 6, figs. 3).—This is a detailed account of the work and observations with rain and with percolation gages as carried out by Latham in England (E. S. R., 22, p. 15).

**Water resources of the Penobscot River basin, Maine, H. K. BARROWS and C. C. BABB** (*U. S. Geol. Survey, Water-Supply Paper 279*, pp. 285, pls. 19, figs. 5).—This paper is "compiled chiefly from the records, reports, and maps of the United States Geological Survey and from the results of surveys made in cooperation with the Maine State Survey Commission. The report includes all data on precipitation, stream flow, water storage, and water power that were available at the end of the calendar year 1909 and is accompanied by plans and profiles of the principal rivers, lakes, and ponds in the basin. It contains also a gazetteer of the water features in the Penobscot basin, by Gertrude E. Schulz."

**Surface water supply of the south Atlantic coast and eastern Gulf of Mexico, 1910, M. R. HALL and J. G. MATHERS** (*U. S. Geol. Survey, Water-Supply Paper 282*, pp. 109, pls. 3).—This paper "contains descriptions of the two drainage basins named and the results of stream measurements in them, namely, gage-height records, results of current-meter measurements, and daily and monthly discharges."

**Surface water supply of Hudson Bay and Upper Mississippi River basins, 1910, R. FOLLANSEEE, A. H. HORTON, and G. C. STEVENS** (*U. S. Geol. Survey, Water-Supply Paper 285*, pp. 318, pls. 4).—Data corresponding to the above are reported for the Hudson Bay and Upper Mississippi River basins.

**Gaging stations maintained by the United States Geological Survey 1888-1910 and Survey publications relating to water resources, B. D. WOOD** (*U. S. Geol. Survey, Water-Supply Paper 280*, pp. 102).—The list of gaging stations is arranged according to drainage basins and the publications chronologically, but with a finding list arranged alphabetically by States. There is also an index of authors and of streams.

**Analyses of artesian and subartesian waters, New South Wales, J. C. H. MINGAYE and H. P. WHITE** (*Rpt. Dept. Pub. Works N. S. Wales, 1911, pp. 48-54*).—Mineral analyses of a large number of samples are tabulated.

## SOILS—FERTILIZERS.

The soil forming processes and the main principles of soil classification, P. KOSSOVICH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 11 (1910), No. 5, pp. 679-703).—The author is of the opinion that a general soil classification can not be based upon any combination of outside soil-forming factors (such as climate, parent rock, topography, plant and animal life, and age) and much less upon any single factor, however great its influence may be. A scientific soil classification should be based rather upon the characteristic inner soil properties and soil forming processes.

Bearing in mind that the greater part of soils is of independent formation but that there are some soils (generally low-lying) which contain weathering products transported from other soils, the author divides all surface soils into 2 main classes, the genetically independent and the genetically dependent. On the basis of soil forming processes he divides the first class into the following types: Dry desert, semiarid desert, chernozem, podzol, tundra, upland moor, and lateritic soils. The genetically dependent soils are divided into soils formed with the addition, respectively, of products of the semiarid, chernozem, podzol, and lateritic soil forming processes. See also a previous note (E. S. R., 12, p. 704).

Soils of arid and of humid regions, E. W. HILGARD (*Internat. Mitt. Bodenk.*, 1 (1912), No. 5, pp. 415-429).—This is a brief summary of the more important results of the author's investigations of the physical and chemical properties of arid and of humid soils which, with the exception of certain of the more recent contributions to the subject, are to be found in the author's book on Soils (E. S. R., 18, p. 315), in publications of the California Experiment Station, and in Wollny's *Forschungen auf dem Gebiete der Agrikultur-physik*, 1893.

Soil investigations in the United States, C. L. HENNING (*Internat. Mitt. Bodenk.*, 1 (1912), No. 5, pp. 440-462).—The author reviews the history and organization of the Bureau of Soils of this Department, and discusses in some detail the methods and extent of the soil survey work of this Bureau, including a brief description of the more important soil series of the different soil provinces of the country.

A contribution to the knowledge of Cuban cultivated soils, E. W. MÜLLER (*Tropenpflanzer*, 15 (1911), No. 12, pp. 660-679).—This is an account of a study of the physical and chemical properties and crop adaptation of these soils. Five main groups of soils are distinguished: A light gray colored, or so-called agricultural group; the yellow, red, and dark soils; and a sandy type developed in Herradura and on the Isle of Pines.

The light gray colored soils occupy the western part of Cuba and constitute the typical tobacco soils of the island. They are residuary in character and contain numerous concretions with a high phosphoric acid content. The concretions of the surface soils are rather hard, rounded, and brown in color. Those of the subsoil approach a red color and crumble easily. Analyses showed as high as 20 to 25 per cent of phosphoric acid in the subsurface concretions. The light gray soils, in general, are open in structure, containing large percentages of stones, gravel, and coarse sand, characteristics which are considered to adapt them for the production of tobacco of a fine grained and an elastic quality, and of superior aroma. They are stated to be well supplied with nitrogen and the mineral constituents of plant food, the analyses reported showing an average nitrogen content of from 0.037 to 0.206 per cent; phosphoric acid, 0.054 to 0.263 per cent; potash, 0.023 to 0.139 per cent; and lime, 0.069 to 0.513 per cent.

The yellow soils occupy the central part of Cuba to the east of Havana. They differ from the light gray soils in their higher content of clay and fewer rock fragments. They have an average content of nitrogen of from 0.115 to 0.286 per cent; phosphoric acid, 0.064 to 0.221 per cent; potash, 0.037 to 0.182 per cent; and lime, 0.127 to 0.892 per cent.

The red soils occupy a considerable area in east central Cuba and are characterized by their high clay content, being derived from weathered limestone rich in iron, alumina, and silica, and by high lime and phosphoric acid contents. Tobacco is the principal crop. In the extreme eastern part of the region there occur rather extensive areas of washed soils which differ from the typical red soils in that they are less porous and more moist. Sugar cane is the principal crop grown thereon. The analyses of these soils showed for nitrogen from 0.192 to 0.290 per cent; phosphoric acid, 0.010 to 0.706 per cent; potash, 0.072 to 0.514 per cent; and lime, 0.278 to 15.040 per cent.

The black soils occupy the eastern lowland region of Cuba. They are noted for their high calcium carbonate and very high nitrogen contents. It is believed that the dark color is due to the large amounts of plant debris from the sugar cane. Analyses showed nitrogen, 0.045 to 0.422 per cent; phosphoric acid, 0.030 to 0.356 per cent; potash, 0.038 to 0.355 per cent; and lime, 1.038 to 53.329 per cent.

The sandy soils of Herradura and of the Isle of Pines are used for the production of citrus fruits. They are stated to be poor in the mineral constituents of plant food, analyses reported showing nitrogen, 0.076 to 0.104 per cent; phosphoric acid, 0.011 to 0.021 per cent; potash, 0.004 to 0.006 per cent; and lime, 0.002 to 0.031 per cent.

The use of fertilizers is stated to be quite general on all the soil types.

Incidentally, analyses of bat guano deposits of the mountain caves of western Cuba are reported. These deposits, although being used as a fertilizer, are not very extensive and are generally low in plant-food constituents.

Soil investigations, W. P. KELLEY (*Hawaii Sta. Rpt. 1911, pp. 43-51, figs. 2*).—Brief reference is made to previous investigations on pineapple soils (E. S. R., 24, p. 621) and an account is given of a further study of movement of water in different Hawaiian soils. These studies included measurements of the rate of capillary rise and percolation of water through columns of soil in glass cylinders.

The results show that capillary movement of water in the soils varies between wide extremes. It was most rapid in the experiments here reported in humus sandy soil and slowest in clay soil. Percolation was slowest through soils containing the highest percentage of clay and fine silt.

Brief reference is also made to a comparison of methods of determining the so-called humus in soils (E. S. R., 27, p. 7) and to the beginning of work on a soil survey of the islands.

The origin, composition, and properties of the manganiferous soils of Oahu, W. P. KELLEY (*Hawaii Sta. Bul. 26, pp. 42-56*).—These soils, which are located on the upland plateau between the Waianae and Koolau Mountain ranges, at an elevation of from 650 to 900 ft., frequently contain 5 per cent of manganese oxid ( $Mn_2O_4$ ) and sometimes as much as from 9 to 10 per cent.

A study of the chemical composition of the lava from which the soils are derived and of the lava alteration products, as well as of the position in which the soils occur, indicates "that the concentration of manganese has come about through the action of solution and leaching, followed by subsequent oxidation and deposition." The manganese has become soluble in the normal weathering of the basaltic lavas and has been transported and redeposited from the solution.

"The occurrence of manganese concretions, the largest in size of which being some depth below the surface, and deposited in the lower levels in the alluvial sheet but not in the sedimentary or residual soil, together with the sharp line of stratification separating the alluvial from the residual strata, indicate that there has been a submergence, during which time the deposition of the alluvial soil and the accumulation of manganese concretions took place. Subsequent leaching further accentuated the accumulation of the manganese in the lower places, especially in basins or at the bases of long slopes.

"The solubility in weak organic acids shows that the availability of the manganese is relatively high and that manganese probably exists in the soil moisture and in solution around the absorbing surfaces of roots in greater quantities than any other element. Therefore it exists in just the condition to exert its full physiological effects on plants. The physical properties of the manganeseiferous soils are more nearly ideal than are those of red soils. They contain less clay, and more of the coarser particles. Consequently the circulation of air is greater in the manganese soil.

"Nitrification and ammonification appear not to be influenced by the presence of manganese in the soil. That the former has been found to take place more advantageously in the manganese soil can probably be accounted for by the fact that the circulation of air is less obstructed in this type."

**Modification of the method of mechanical soil analysis.** C. C. FLETCHER and H. BRYAN (*U. S. Dept. Agr., Bur. Soils Bul. 8*), pp. 3-16, pls. 7).—This bulletin describes the apparatus and methods used in making the mechanical analysis of soils as at present carried out in the laboratory of the Bureau of Soils.

The most important modification of previous methods is that for determining the amount of clay. It was decided to abandon the final transfer of the clay solution to the platinum dishes and to complete the evaporation in the enameled-ware saucepans and to weigh the clay in them without transfer. Much smaller enameled cups (about 300 cc. capacity and 180 gm. weight) were adopted for convenience in weighing and to decrease the likelihood of the entry of dust. It is stated that the method has the disadvantage of requiring a much heavier balance, but the determinations are none the less accurate and a great saving in time is effected. The method may be still further shortened in case of routine analyses by abandoning altogether the direct determination of clay and obtaining its percentage by difference. "The error thus introduced is probably no greater than that involved in the centrifugal (or other) separation of the clay from the silt. The errors in both cases are generally within the limits of variation which may be expected between different samples of the same soil.

"In 100 consecutive analyses taken at random from the recent files of the Bureau of Soils the variations between the percentage of clay as directly determined and those obtained by difference range between 0 and 2.28 per cent. In 2 cases the variation is over 2 per cent; in 3 cases, between 2 per cent and 1.5 per cent; and in 6 cases between 1.5 per cent and 1 per cent. In all other cases the variations were less than 1 per cent.

"It is probable that in many cases the determination by difference is the more accurate, as all errors due to access of dust or to loss of clay suspension are thus avoided. Errors due to a not impossible change in the state of hydration of the clay are also eliminated. It is believed that in the vast majority of cases the method of determining clay by difference will be accurate within 1 per cent, and no greater accuracy is necessary or even desirable for purposes of soil classification. . . . The direct determination must, of course, be retained for cases of special importance or where a check is necessary, and is probably also desirable for students and for small laboratories where a mechanical analysis is only made occasionally."

The estimation of certain physical properties of soil, G. AUCHINLECK (*West Indian Bul.*, 12 (1912), No. 1, pp. 50-68).—In this article an attempt is made to coordinate the work of a number of investigators in the West Indies in estimating the shrinkage and friability of soils and the relation between these properties of the soil and its crop-bearing power.

In determining the shrinkage the soil sample was first kneaded to a proper degree of plasticity. "A brick is then made by pressing the kneaded sample into the space between 2 small cleats nailed on a length of board, the cleats being 1 in. high, 1 in. apart, and 3 in. long. The ends and top of the brick are then trimmed level with the edges of the cleats, and the brick removed. Two fine pins are inserted to their heads into the brick, at as nearly as possible 50 mm. apart, and the interval between them accurately measured with a pair of dividers or directly by means of a scale. The brick is then laid on its side and left to dry gradually, and the interval between the pins is measured daily until shrinkage ceases."

Trials with this method on the surface and subsoil of several cacao fields showed that cacao did not grow well in surface soils with a shrinkage of over 10 per cent, whereas in soils under 10 per cent good growth was made. In subsoils with a shrinkage of over 12 per cent the plant did poorly, and under 12 per cent good growth was made. It is believed "that the estimation of shrinkage is capable of a considerable degree of accuracy. Future efforts should be along the lines of erecting standards of shrinkage for various crops, and of investigating further the accuracy of the standard temporarily adopted for cacao. The subsoil should be looked on as of perhaps greater importance than the top soil when dealing with deep rooting and permanent crops. Much good work remains to be carried out in determining the limits of shrinkage to be assigned to soils for various crops, and citrus fruits, cotton, rubber, sugar cane, and spices should eventually be brought under the similar standards and have their respective suitable areas assigned to them."

The determinations of friability were carried out by molding cylinders of soil of definite diameter and length and subjecting them to end-pressure until they broke, the weight necessary being recorded. The method was found to be accurate enough to classify soils on broad lines. As with the determination of shrinkage, it is believed that the method can be much improved and that standards of friability for soils and for special crops should be erected. The ratio of shrinkage to clay content in samples of a given soil may "afford a ready means of determining the approximate percentage of agricultural clay in a sample of soil, without having recourse to elaborate and tedious methods of physical soil analysis; if so, it should serve as a valuable aid to the soil analyst, inasmuch as it would enable a considerable amount of useful information to be obtained with a small expenditure of labor. Once a physical type for a soil has been established, it should be possible to study by means of it, in considerable detail, local variations from the type."

The determination of hygroscopicity and the value of physical analyses of soils, E. A. MITSCHERLICH and R. FLOESS (*Internat. Mitt. Bodenk.*, 1 (1912), No. 5, pp. 463-480).—In comparative tests of the Rodewald-Mitscherlich method of determining the hygroscopicity (E. S. R., 15, p. 847) and of the Ehrenberg-Pick modification of it (E. S. R., 24, p. 521), and studies of the relation of hygroscopicity and physical constitution of soils to plant growth, the Ehrenberg-Pick modification proved unreliable because of the condensation of water and the growth of molds in the soil as a result of the length of time required to bring about vapor equilibrium. The hygroscopicity, as determined by this method, varied with the water content of the original soil, and changes in the surface area of the soil could not be estimated. The importance of hygro-

scopcity and the colloidal material of the soil in relation to the physics and chemistry of plant growth is discussed.

The drying of soils, G. A. RITTER (*Centbl. Bakt. [etc.]*, 2. *Abl.*, 33 (1912), No. 1-6, pp. 116-117).—Studies are reported of the bacterial activity of wet and of dried soils as measured by the formation of acid and of carbon dioxide in culture solutions, as affected by the physical and chemical properties of the soil, the character of the culture medium, the kind of vegetation, alternate drying and wetting, rate and degree of drying, and temperature. The Remy method or a modification of it was used.

There was found to be a difference in the bacterial activity of the dry as compared with that of the wet soils, the dry soils causing a quicker and more intense fermentation. These differences were most marked at the beginning of fermentation but later tended to disappear. The time of reaching the maximum formation of acid varied for the different soils, but always was shortest for the dry soils. The maxima of acid formation varied with the different kinds of soil as well as with the water content of a given soil, although the latter variation, excepting in a wet and heavy clay soil, was for the most part unimportant and often fell within the limits of experimental error. The calcium carbonate content of the soils also influenced somewhat the formation of acid, but the virulence of the bacteria as determined by the physical and chemical properties of the soil was the determining factor. It is held that the extent of variation in the physiological relations in wet and in dry samples of the same soil is determined by or is a function of the bacterial activity of the soil.

The author asserts that the Remy method of bacteriological soil investigations is correct in principle. He urges that attention be given to the elimination of variable factors which may vitiate the results, such as variable water content of the soil, careless methods of preserving soil samples, and variations in temperature and light.

The oxygen content of soil water and its influence on the swamping of the soil and the growth of forests, A. H. HESSELMAN (*Meddel. Stat. Skogsförsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens)*, 1910, No. 7, pp. 91-125 + XIII-XVI, figs. 5).—Studies of the oxygen content in surface and subsoil waters of forest swamps and of the absorption of oxygen from water by different forest molds and soils are reported with a view of determining the cause of the swamping of pine forests in northern Sweden.

The results, in general, showed that where there was sufficient movement the water was well supplied with oxygen. The water of the moors of swamped pine forests contained no oxygen at a depth of 20 cm. Near the surface it contained traces of oxygen. Sphagnum layers reduced the oxygen content of the water. The absorption of oxygen was much less for beech forest than for pine forest soils and for sterilized neutral than for unsterilized soils, and less for the humus of a rapidly growing pine forest than for that of a swamping forest.

The general conclusion drawn from these studies is that the swamping of forest soils of Sweden is not due to overabundance of water but to its low oxygen content. In some places, where the water was in motion and thus aerated, pine forests made a very vigorous growth even where the soil was covered with water.

Evaporation from irrigated soils, S. FORTIER and S. H. BECKETT (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 218, pp. 77, pls. 2, figs. 27).—This bulletin reports a continuation of experiments reported upon in a previous bulletin (*E. S. R.*, 18, p. 1087), extending the observations to colder and more elevated regions.

Observations by the methods described in the previous bulletin were made in cooperation with several experiment stations on the effect on evaporation with

soil mulches of different depths, cultivation to different depths, and shallow and deep furrow irrigation.

The results show that a dry granular soil mulch 3 in. deep reduced the loss by evaporation from the soil at least one-half, a mulch 6 in. deep saved 75 per cent of the evaporation, and a 9-in. mulch was still more effective in reducing evaporation, but was too expensive to be of practical value. The effect of cultivation in lessening evaporation was especially marked in case of the heavier soils. "There is a tendency in light sandy soils for the uncultivated surfaces to mulch themselves, and after the first few days following the irrigation the losses diminish very rapidly, and in the end little advantage is shown in favor of cultivation."

The loss of water decreased with the depth of application. "Practical considerations, however, limit the depth. Under conditions such as exist throughout the arid region this practical limit lies, it is believed, somewhere between 6 and 9 in. . . . In general, it may be stated that wherever the soil and the crop will permit the water should be applied in deep furrows rather than by flooding; that one deep, heavy irrigation is preferable to numerous lighter irrigations, providing the crop is deep-rooted; that cultivation should be practiced as early as possible after irrigation; and that deep and frequent cultivation prevents evaporation and aerates the soil."

**Effect of heat and oxidation on the phosphorus of the soil, P. P. PETERSON** (*Wisconsin Sta. Research Bul. 19, pp. 16*).—The author briefly reviews previous investigations on the subject, and reports the results of studies of the effect of heat and of oxidation with hydrogen peroxid on the solubility of phosphoric acid of the soil and of wavellite and dufrenite.

Heating wavellite for 5 hours to 200° increased the solubility of the phosphoric acid from 4 to 50 per cent, and heating it to 240° increased the solubility to 100 per cent. Dufrenite, when heated to 200°, was but slightly increased in solubility.

The increase in solubility of the phosphoric acid of the soil was small at 130° and rose rapidly with a rise in temperature above this point, reaching a maximum at 200°. The solubility of the phosphoric acid in clay and clay loam soils was increased on an average about 50 per cent by decomposing the organic matter with hydrogen peroxid. For sandy soils the increase was about 30 per cent. The increase in solubility by treating with hydrogen peroxid was always larger than that due to heating, and there was no increase in solubility by heating after treatment with hydrogen peroxid. The phosphoric acid rendered soluble by heating was from the same source as that obtained from oxidation with hydrogen peroxid. The solubility of the mineral phosphates of the soil did not seem to be increased by heating to 240°. The increase in solubility was greater in the early than in the later stages of oxidation, being greatest when from 25 to 30 per cent of the organic matter had been decomposed and ceasing with 60 per cent.

The solubility of calcium and manganese was not increased by oxidation, that of iron and aluminum was increased, the increase following pretty closely that in the solubility of phosphoric acid. "The increased solubility of phosphorus by oxidation with hydrogen peroxid probably comes, in large part, from precipitated iron and aluminum phosphates, held from solution before the oxidation as part of a complex of insoluble organic matter and compounds of iron and aluminum. Oxidation increases the solubility of the phosphorus but slightly in subsoils. Heating after oxidation has a more marked effect on the solubility of the phosphorus in the subsoil than it has in the surface soil."

Methods of determining the intensity of respiration of bacteria in the soil, J. STOKLASA (*Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 11, pp.*

1243-1279, figs. 2; abs. in *Internat. Inst. Agr. [Rome]. Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 2, pp. 376-378).—This is a report of a continuation and extension of previous work by the author (E. S. R., 18, p. 1024). A special form of apparatus used in these investigations is described, and the results of studies of the effect of cultivation, fertilization, kind of crop, and composition of organic matter on the intensity of respiration of bacteria in the soils are reported.

The essential part of the apparatus used was a glass cylinder fitted with a sieve at about 5 cm. from the bottom. The soil was placed in the upper part of the cylinder, and sterilized air (or hydrogen for anaerobic bacteria) was introduced into the bottom of the cylinder by means of a glass tube. A second tube, projecting a few centimeters into the top of the cylinder, conducted the carbon dioxide evolved from the soil through the apparatus for its absorption and determination. The cylinder containing the soil was kept in a thermostat during the experiment so that the temperature could be carefully regulated.

The bacterial activity as measured by the amount of carbon dioxide given off was influenced not only by the mechanical condition and fertility of the soil, but also by the kind of crop grown. The greater the air space of the soil the greater was the intensity of respiration of the bacteria.

By sterilizing the soil and inoculating it with equal quantities of bacteria of the same virulence it was possible to determine by means of the carbon dioxide given off the power of the bacteria to decompose the organic matter in the soil, and the author concludes that intensity of respiration of bacteria is a better basis for judging the biological activities of soils than the amount of organic matter present. Intensity of respiration shows the presence in the soil not only of active bacteria but also of easily decomposed organic matter.

The chemical composition of the drainage water was also found to furnish a means of judging the intensity of the biochemical processes in the soil. It was found, for example, that the calcium bicarbonate content of the drainage water increased with the bacterial activity, irrespective of the lime content of the soil, and stood in direct relation to the carbon dioxide produced by the soil micro-organisms. This tends to show that the determination of the carbon dioxide given off by a soil furnishes a reliable means of judging of the transforming power of both autotrophic and heterotrophic bacteria in the soil, and that the amount of carbon dioxide produced by a given quantity of soil in a unit of time at a fixed temperature and known degree of moisture represents accurately the physiological combustion taking place and makes it possible to compare the bacterial activity in different soils. This varies widely with (1) the air or water capacity of the soil, (2) the character and amounts of decomposable organic matter in the soil, (3) the presence of organic and inorganic nitrogenous substances and of easily assimilated substances containing phosphorus, potash, etc., (4) the number of autotrophic and heterotrophic bacteria, and (5) the chemical reaction of the soil.

The most active respiration occurs in neutral or slightly alkaline soils abundantly supplied with air and with readily assimilable nitrogen, phosphorus, sulphur, chlorine, potash, soda, magnesia, lime, iron, alumina, and manganese. The presence of alumina is necessary to the ready assimilation of iron and manganese by autotrophic and heterotrophic bacteria.

The form of nitrogen has a marked influence in determining the character of bacteria predominating in a soil, and hence the intensity of respiration. In forest soils, for example, bacteria which by preference assimilate organic nitrogen predominate. In soils in which nitrification is active the predominant bacteria are those which readily assimilate nitric nitrogen. On the other hand,

bacterial respiration is intensified by applications of various substances to the soil according to the character of the bacteria present. Those soils showing low bacterial activity are likely to be most benefited by applications of nitrates. If applications of monocalcium phosphate and potassium chlorid increase the production of carbon dioxide this is an indication that the soil is deficient in assimilable phosphoric acid and potash.

**Toxic effects of "alkali salts" in soils on soil bacteria.—II, Nitrification,** C. B. LIPMAN (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 33 (1912), No. 11-14, pp. 305-313, figs. 2).—This is a second communication on this subject, the first (E. S. R., 26, p. 322), dealing with the effect of the alkali salts on ammonification.

Summarizing his results, the author concludes that "nitrification in soils is inhibited by the presence of certain amounts of each of the 'alkali salts' sodium chlorid, sodium sulphate, and sodium carbonate. Sodium carbonate is the most toxic, sodium sulphate the least toxic, and sodium chlorid occupies an intermediate position. The actual points at which these salts become markedly toxic toward nitrification in soils are at about 0.025 per cent sodium carbonate, 0.35 per cent sodium sulphate, 0.1 per cent or less of sodium chlorid. The anion bears an important relation to the toxic effects of salts as illustrated in the results above discussed, a fact which has not received very much consideration in the past. The salt effects noted should, like results obtained on ammonification in work above cited, have an important bearing on the practical reclamation of alkali lands. The nitrifying bacteria are affected similarly to the higher plant by the alkali salts and quite differently from the ammonifying bacteria."

**Maintenance of soil fertility: Plans and summary tables (Ohio Sta. Circ. 120, pp. 95-115, figs. 5).**—This is one of the annual statements on the subject (E. S. R., 26, p. 423), bringing the data for the experiments up to the end of 1911 and summarizing the results for 18 years (1894-1911).

**Reaction changes in the soil by growth of plants and fertilizing, J. G. MASCHHAUPT (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1911, No. 10, pp. 50-93, pls. 4; abs. in Chem. Abs., 6 (1912), No. 11, p. 1487).**—Previous investigations on the subject are reviewed, and studies of the effect of the growth of plants on the reaction of solutions of ammonium, potassium, sodium, calcium, and magnesium nitrates, sulphates, and chlorids are reported.

The tests were made (1) by growing the plants in soil in flowerpots with perforated bottoms, the roots being allowed to dip into breakers which contained, alternately, pure solutions, and sand saturated with solutions of the salts named; and (2) by growing the seedlings in the solutions of the salts. It is stated that the first method was well adapted for the purpose of these experiments and that it has a decided advantage in that the plants are grown in the natural soil conditions. Better results were obtained when the roots of the seedlings were first developed to some extent in a culture solution before transferring to the solutions of pure salts. It was thought that a study of the effect of plant growth on the reaction of the solutions would indicate the conditions which may arise in the soil from continued application of a fertilizer containing a predominance of any one salt.

The results of the studies show that sodium nitrate was physiologically alkaline. In one case, using rye, an alkalinity of 0.006-normal was obtained. The alkalinity was substantially increased in sand culture, 0.028-normal being obtained with corn. Ammonium sulphate was physiologically acid, the highest degree of acidity being 0.015-normal obtained with corn in sand culture. Ammonium nitrate was physiologically acid but less so than the sulphate. This result is stated to agree with the work of D. N. Prianishnikov (E. S. R., 17,

p. 538), who observed a favorable influence of ammonium nitrate on the assimilation of phosphoric acid from difficultly soluble phosphates. In 2 tests, with the entire root system in the solution, ammonium nitrate gave a weakly alkaline reaction. Potassium nitrate was generally physiologically alkaline, but weaker than sodium nitrate. Calcium nitrate was physiologically alkaline. Ammonium chlorid was decidedly acid, and very injurious to the roots. Solutions of potassium, sodium, magnesium, and calcium chlorids and sulphates were weakly alkaline.

The general conclusion drawn from these studies is that the change in the reaction of the solutions was not determined solely by the process of assimilation of one or of the other ion by the plant roots, but that there was an exosmose of calcium and potassium (and probably other elements) from the root cells. This phenomenon of exosmose is regarded as the probable explanation of the toxicity of the solutions of pure salts and makes intelligible the action of calcium salts in lessening the toxicity of pure salt solutions.

**Influence of phosphatic and potassic fertilizers on the chemical composition of the forage of natural pastures.** P. CHAVAN (*Ann. Agr. Suisse*, 12 (1911), No. 4, pp. 259-272, figs. 3).—Analyses of grasses, legumes, and other plants growing on Alpine grass lands near Sèchey, Switzerland, are reported, showing that fertilizing with phosphates increased the cellulose content of the plants as a result of the influence of the phosphoric acid in hastening maturity. Fertilizing with phosphates and potassic fertilizers increased the phosphoric acid and potash content of the ash of the plants. The use of both fertilizers, but particularly the phosphatic fertilizer, promoted the absorption of nitrogen from the soil by Gramineæ and other families of plants. They also increased the fertilizing effect of the organic matter of the soil. Phosphatic fertilizers increased the potash content of the plants. These results differ materially from those reported by A. Stutzer, who found that phosphatic fertilizers had little effect upon the yield of Gramineæ, increased but slightly their content of phosphoric acid, and did not increase the potash and nitrogen content of the plants.

**The after effect of fertilizing with various potash rocks on moor soils.** H. VON FEILITZEN (*Deut. Landw. Presse*, 39 (1912), No. 21, p. 259, fig. 1).—A brief account is here given of comparisons of phonolite, nephalin, and similar substances with potash salts. These showed that there was an appreciable after-effect of both the phonolite and the nephalin, but that during the second year as well as the first the increase did not compare with that obtained with the water-soluble Stassfurt salt.

**Experiments on the action of kainit, 40 per cent potash salt, and phonolite, 1904-1910.** W. SCHNEIDEWIND, D. MEYER, and F. MÜNTER (*Arb. Deut. Landw. Gesell.*, 1911, No. 193, pp. 173; *abs. in Zentbl. Agr. Chem.*, 41 (1912), No. 3, pp. 165-170).—This is a detailed account of pot experiments on (1) absorption of potassium and sodium salts in fall and spring fertilizing, (2) the action of sodium chlorid and sulphate and magnesium chlorid and sulphate on fodder beets, (3) the action of increasing amounts of sodium and magnesium chlorids and magnesium sulphate on plant growth, and (4) the action of phonolite and Pohl zeolite fertilizer (lime trass) in comparison with potassium chlorid and carbonate; and field experiments comparing the potash fertilizers named on potatoes, sugar beets, fodder beets, wheat, rye, and barley.

Among the more important general conclusions arrived at from these experiments were that spring application of potash fertilizers gave decidedly better results than fall application on sandy soils in case of pots which had not been freshly filled in the fall. This is ascribed to the washing out of potash from the soil with fall application. Spring applications were better in all cases with

loam soils. This result is ascribed to the strong absorptive power of such soils for potash.

A decided increase in yield of fodder beets followed applications of sodium chlorid and sodium sulphate, especially the former. No such result was obtained in the case of magnesium salts, and magnesium chlorid was positively harmful. Magnesium chlorid, and in certain cases sodium chlorid, increased the assimilation of soil potash without increasing the yield.

Large applications of magnesium sulphate (0.25 to 0.5 per cent) produced beneficial results, especially on calcareous loam soils, and even with applications of 1 per cent there was an appreciable increase in yield of grain on such soils. Similar results were obtained with sodium sulphate. On sandy soils, however, the sulphates were injurious in all cases, but not to the same extent as the chlorids. Magnesium and sodium chlorids applied at the rate of 0.25 per cent were not injurious on calcareous loam soils, but were injurious when applied in double this amount. On loam soils poor in lime applications of 0.25 per cent reduced the yield of grain and on sandy soils these salts in all amounts applied absolutely prevented the growth of plants. The chlorids increased the assimilation of lime while the sulphates reduced it.

It is pointed out that these results obtained in pot experiments are obviously not applicable in practice except in so far as they indicate that sulphates may be safely used in larger amounts than the chlorids. Phonolite showed very little effect as compared with potassium chlorid and carbonate applied to potatoes, wheat, and a mixture of oats and clover.

The field experiments indicated that potash salts were not needed for potatoes which had received a liberal application of manure. On sandy soils spring application of potash salts gave better results than fall application. The percentage of starch was lower, but the total yield was larger. On loam soils the reduction in starch was greater than that in sandy soils. There was little difference as regards the effect of spring and fall application, except that in general the starch was reduced to a greater extent by spring application. The yield was slightly less with 40 per cent potash salt, and the starch content slightly greater, than with kainit. Normal applications of phonolite were almost without effect; larger applications had little effect upon yield but showed less reduction of starch content than the potash salts. Potassium carbonate increased the starch content of potatoes.

The potash fertilizers increased the yield of dry matter and sugar in sugar beets on all soils, the best results being obtained with fall application. On loam soil 40 per cent potash salt and kainit were about equally effective. The 40 per cent salt was slightly better on heavy soils. Phonolite was almost without effect on sugar beets.

Potash salts increased the yield of fodder beets both with and without manure except on humus soils (with manure). Slightly larger yields were obtained with fall application. The 40 per cent salt gave a slightly larger yield of dry matter than kainit. Like the potato, but unlike the sugar beet, the fodder beet appears to be especially sensitive to large applications of potash salts. Phonolite had little effect.

Fall application of potash salts gave better results than spring application on wheat. Kainit and 40 per cent salt were about equally effective on humus loam soil. On heavy loam soil the 40 per cent salt gave better results. Phonolite was ineffective.

No benefit was obtained from the use of potash salts on rye. The results were very variable with barley, and were inconclusive as regards spring and fall application. The 40 per cent salt appeared to be somewhat more effective than the kainit for this crop.

On the availability of the potash in "rapakivi" and pegmatite granites. O. ASCHAN (*Ztschr. Anorgan. Chem.*, 74 (1912), No. 1, pp. 55-73; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 4, p. 195).—These granites were subjected to various treatments, including the action of lime water, sulphuric acid, hydrochloric acid, calcium chlorid, lime and salt mixture, and peat, in order to find a practical means of rendering the potash which they contain in the form of feldspar available for fertilizing purposes.

The results indicate that treatment with acids is not a practical method. Practically complete solution of the potash was obtained by fusion with calcium chlorid or with lime-salt mixture, the former being considered perhaps the better method if the calcium chlorid can be obtained cheaply. The greater part of the potash was made soluble as hydroxid by heating under pressure with lime water. The solubility of the potash and phosphoric acid in the fine ground feldspar was increased to a marked extent in the course of 6½ months when mixed with moor soil at the rate of 1 part of feldspar to 9 of soil. The solubility was still further increased when ammonium sulphate was added to the mixture.

Factors influencing the availability of rock phosphate. E. TAYLOR (*Wisconsin Sta. Research Bul.* 20, pp. 17-51, figs. 4).—Previous investigations on this subject are reviewed, and studies of the effect of fermenting manure and grass, and of thoroughness of mixing with the soil, on the availability of floats are reported.

In laboratory experiments in which organic matter was composted with raw phosphates there was little or no solvent action of the fermenting material. The solvent action was apparently measured by the amount of phosphate which the water containing carbon dioxide could hold in solution, and in the laboratory experiments a state of equilibrium in this respect was quickly reached and there was no further solvent action. Under field conditions, however, there was a continual removal of the dissolved substances, resulting in conditions which greatly increased the solvent action of the carbon dioxide.

The mixing of floats with manure caused an immediate decrease in the solubility of the phosphoric acid in 0.2 per cent citric-acid solution, indicating "that the availability of phosphates as measured by a solvent like 0.2 per cent citric acid may be entirely different from availability as measured by growing crop."

When floats was thoroughly mixed with the feeding area of the soil its availability was increased to such an extent that some species of plants were apparently able to secure almost an adequate supply of phosphoric acid from this material. Apparently the carbon dioxide given off by the plant roots was instrumental in increasing the availability of the phosphoric acid of the floats. The addition of manure to the soil greatly increased the carbon dioxide production and for a short time measurably increased the solvent action on floats.

The general conclusion, therefore, is that the use of organic matter in connection with floats increases its availability to plants. "The organic matter brings about this increased availability by favoring a more efficient initial mechanical distribution of the floats with the soil and by favoring the chemical and biological processes that give rise to carbon dioxide and other agencies which attack floats and ultimately give the material a finer and more uniform distribution through the soil."

Report of a reconnoissance of the Lyon nitrate prospect near Queen, N. Mex., E. E. FREE (*U. S. Dept. Agr., Bur. Soils Circ.* 62, pp. 6, figs. 5).—The examinations reported show the occurrence of small amounts of potassium nitrate, but not enough "to have any important commercial value."

The present status of the artificial nitrogen fertilizer industry, F. W. DAFERT (*Ztschr. Landw. Versuchsw. Osterr.*, 15 (1912), No. 1, pp. 107-119; *Monatsh. Landw.*, 5 (1912), No. 1, pp. 1-8).—This is a review of the present status of the manufacture of ammonium sulphate, nitric acid, lime nitrogen, and nitrids, describing briefly the principal processes which have been proposed for this purpose and have shown commercial possibilities. The author is of the opinion that among these are processes which can be profitably used whenever there is commercial necessity for supplementing present supplies of nitrogenous fertilizers.

Some recent experiments with calcium cyanamid or nitrolime, and their practical bearing (*Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 3, pp. 649-657).—This is a summary of the more important results of the principal recent investigations on this subject, with a bibliography of 18 references.

Marl for soil improvement from various formations in Hanover, A. ROSEN-BACH (*Jour. Landw.*, 59 (1911), No. 4, pp. 407-418; *abs. in Chem. Abs.*, 6 (1912), No. 5, p. 663).—Attention is called to the variation in the use of the term marl, and it is pointed out that many so-called marls contain a very small amount of lime and owe their fertilizing value chiefly to their phosphoric acid content. This is true of a large number of marls and associated deposits from the region of Göttingen, of which analyses are reported.

The sootfall of London: Its amount, quality, and effects (*Lancet [London]*, 1912, I, No. 1, pp. 47-50, fig. 1).—This article reports observations on the amount and character of soot falling in London, from which it is estimated that on the 117 square miles comprising the administrative county of London, including the city proper, there is an annual sootfall of 76,050 tons containing 6,000 tons of ammonia, 8,000 tons of sulphate ( $\text{SO}_4$ ), and 3,000 tons of chlorine as chlorides.

Fertilizers: Their source, purchase, and use, C. B. SMITH (*Redlands, Cal.*, 1911, 2. ed., rev. and enl., pp. 67, pls. 2, figs. 2).—This is a second revised and enlarged edition of this book, which, it is stated, was "written for the use of farmers and fruit growers, with special reference to citrus culture."

Fertilizers in 1912, C. GUFFROY (*Vie Agr. et Rurale*, 1912, No. 10, pp. 233-240).—A brief review is given of progress in fertilizer investigations in 1912, more particularly those relating to the fertilizing effect of manganese, sulphur, magnesium, chlorine, sodium chlorid, boron, chromium, and radioactive minerals, soil inoculation, rôle of water in plant growth, standard and new nitrogenous fertilizers, phosphatic and potassic fertilizers, lime, gypsum, and manure, as well as those bearing on the use of fertilizers against plant parasites and diseases.

Inspection and analyses of commercial fertilizers, P. F. TROWBRIDGE ET AL. (*Missouri Sta. Bul.* 99, pp. 117-181).—Analyses and valuations of 338 samples of fertilizers inspected during the spring and fall of 1911 are reported.

Commercial fertilizers (*Off. Rpt. Sec. Ohio Bd. Agr. on Com. Ferts.*, 1911, pp. 208).—This is a report of the official fertilizer inspection in Ohio in 1911, giving the text of the fertilizer law which became effective December 1, 1911, and analyses and valuations of 695 brands of fertilizers examined during the year, with discussions of the results and of the nature, purchase, and use of fertilizers.

Tabulated analyses of commercial fertilizers, W. FREAR (*Penn. Dept. Agr. Bul.* 218, pp. 77).—This bulletin gives the results of fertilizer inspection, including analyses and valuations, in Pennsylvania from August 1 to December 31, 1911.

Licensed commercial fertilizers, 1912, F. W. WOLL (*Wisconsin Sta. Circ. Inform.* 31, pp. 12, 13).—A list of manufacturers and brands licensed for the year 1912.

## AGRICULTURAL BOTANY.

The function of manganese in plant growth, W. P. KELLEY (*Hawaii Sta. Bul.* 26, pp. 7-41).—A study has been made of the function of manganese in plant growth, in which the author, after describing its occurrence in plants and reviewing previous investigations, gives accounts of field and pot cultures with different plants, the principal observations being made with pineapples.

It was found that different species of plants vary decidedly when grown on manganiferous soils. Some are stunted in growth and die back from the tips of the leaves, while others appear unaffected and so far as can be determined vegetate normally in the presence of manganese. Microscopic investigations showed that certain changes take place in the protoplasm of the cells, the chlorophyll in a number of plants being affected. In pineapples it undergoes complete decomposition, the chloroplasts often becoming disintegrated and losing their granular structure. Simultaneously with the destruction of chlorophyll starch formation ceases. The occurrence of oxidizing enzymes in plants appears to bear no direct relation to the destruction of chlorophyll under the influence of excessive amounts of manganese, and there seems to be no correlation between the phenomenon of chlorosis in pineapples and the activity of the oxidizing enzymes.

From ash analyses it was found that manganese was absorbed in considerable quantities, and that the ratio of absorbed lime to magnesia increased under the influence of manganese, regardless of whether the plant exhibited any toxic effects. The author believes that the effects of manganese are largely indirect and are to be explained on the basis of its bringing about a modification in the osmotic absorption of lime and magnesia. The toxic effects are chiefly due to this modification, rather than as a direct effect of the manganese itself.

Where small amounts of manganese occur in natural soils it is believed that a twofold function in plant growth is performed. The manganese acts catalytically, increasing the oxidations in the soil and accelerating the auto-oxidations in plants, and it tends to modify the absorption of lime and magnesia by partially replacing calcium from insoluble combinations and through a direct effect on the osmotic absorption of lime and magnesia.

The absorption of phosphoric acid by plants grown on manganiferous soil was found to be decreased, possibly due to the precipitation, by the manganese of the phosphoric acid into a difficultly soluble compound.

The application of lime to manganiferous soils was found to result in a more intense yellowing. On the other hand, the application of soluble phosphates tends to ameliorate the effect of an excess of manganese. In practice this is the only means known to be efficacious, but in the case of pineapples it does not entirely prevent the development of the yellow color.

The form in which manganese is absorbed is not definitely known, but it is suggested that it is probably as a manganite of calcium.

The influence of manganese on the growth of *Aspergillus niger*, G. BERTRAND and M. JAVILLIER (*Bul. Soc. Chim. France*, 4. ser., 11 (1912), No. 5, pp. 212-221).—In continuation of previous investigations by the authors on the effect of manganese, zinc, etc., on plants (E. S. R., 25, p. 325), a study is reported on the action of manganese on the growth of *A. niger* in cultures, special efforts having been made to remove all traces of zinc, sulphur, etc., from the manganese. Varying proportions of manganese were added to Raulin culture media and the effect on the growth of the fungus was observed. The amount of manganese was varied from 1 part per million to 1 part in 50. In all the experiments there was found a stimulating effect that rapidly increased

with the concentration to an optimum, after which the growth was gradually reduced.

In a second series of experiments an attempt was made to determine the assimilation of manganese by the fungus. It was found that the increased weight of the mold was due not only to the manganese assimilated but also to the stimulating effect the chemical produced on the assimilation of other compounds by the fungus.

The amount of manganese fixed was found quite small in proportion to the total amount at the disposal of the plant, and it did not appear to be of physiological use within the cells. It either simply colored the cell wall or was changed into insoluble forms. The greatest stimulation to growth appeared when manganese was used in the proportions between 1 part to 10,000 and 1 part to 500. The manganese appeared to stimulate the production of conidia, as shown by differences in color of the growth on the media.

The stimulating action of manganese and copper sulphates on plants, L. MONTEMARTINI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 7, pp. 564-571; *abs. in Internat. Inst. Agr. [Rome], Bul. Eur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, pp. 2467, 2468).—A study has been made of the effect of very dilute solutions of the sulphates of manganese and copper on the development, respiration, and photosynthesis of grapes, lupines, beans, and potatoes, and the flowers of *Leucanthemum* and *Ageratum*. Comparisons were drawn between the carbon dioxide liberated and the proportion of the different substances absorbed by the plants. The manganese solutions varied from 0.001 to 0.025 per cent and the copper sulphate from 0.005 to 0.05 per cent.

The results show that when these salts were absorbed by the plants in very small quantities both exerted a stimulating effect on the growth of all the plants. Marked differences were noted in the sensitiveness of the different plants, as shown by their respiration. Grapes were the most sensitive, followed by beans and potatoes in the order enumerated. The flowers of plants were found to exhibit more sensitiveness to the chemicals than the leaves. Unopened flowers were more sensitive than open ones. Photosynthesis was stimulated more than respiration, and it varied to some extent with the different plants.

The growth of wheat seedlings as affected by acid or alkaline conditions, J. F. BREAZEALE and J. A. LECLERC (*U. S. Dept. Agr., Bur. Chem. Bul.* 149, pp. 18, pls. 8).—A report is given of a physiological study to determine the effect of the reaction of the culture medium on the growth of wheat seedlings and particularly on the development of the root. Seedlings were grown in water cultures containing various amounts of sodium nitrate, potassium chlorid, potassium sulphate, hydrochloric acid, and sulphuric acid, singly and in combination with calcium carbonate. Two crops of seedlings were grown in the solutions, and the effect on germination was noted. Another series of experiments was conducted in which aluminum and ferric hydroxids were used to reduce the acidity of the solution, and still another series in which clover and timothy were grown in connection with wheat.

The investigations show that the seedlings grown in culture solutions containing potassium chlorid, potassium sulphate, or hydrochloric or sulphuric acid solutions (10 parts per million) exert a selective action whereby the potash ion is absorbed by the roots and the chlorid and sulphate ions are for the most part left in solution. This causes the solution to become acid, which in turn acts injuriously on the root development. The addition of iron or lime or aluminum hydrate to the media containing the other compounds used tended to keep the solutions alkaline so that they acted favorably on the root development.

New studies on narcosis in plants, O. RICHTER (*Mitt. Naturw. Ver. Univ. Wien*, 9 (1911), No. 1, pp. 14, 15; *abs. in Bot. Centbl.*, 116 (1911), No. 24,

*p. 616*).—The author gives the results of his investigations on plants regarding the differences observable in chemical composition, etc., between plants exposed to an atmosphere of narcotics and those in air. These in the main may be summed up as follows: Plants in a narcotic atmosphere show (1) increase of soluble, osmotically active compounds, as sugar, asparagin, etc.; (2) heightened turgor; (3) cells growing in a form shorter but thicker with other cell modifications, as increase of collenchyma, epidermal thickenings, vacuolization and fusion of cells, etc.; (4) lessened synthesis of proteins and coloring matters; (5) alterations of negative geotropism; and (6) increase of heliotropic sensitiveness.

The stimulation of plants through small quantities of poisonous substances, E. B. FRED (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 31 (1911), No. 5-10, pp. 185-245, figs. 4; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 590, II, *p. 1123*).—A detailed account is given of experiments in which ether, carbon bisulphid, potassium bichromate, copper sulphate, and Salvarsan were tested on various organisms. It was found that their effect is a biological one and that when used in sufficient dilutions they promote the growth of *Azotobacter* and of denitrifying, ammonifying, and various putrefactive bacteria and yeasts.

Ether in a suitable quantity increased the nitrogen fixation by *Azotobacter* in soils, and both ether and carbon bisulphid increased nitrogen fixation in pure cultures, but not so much as in mixed cultures taken directly from soil. This is probably due to *Azotobacter's* possessing a greater resistance to the chemical materials used than the other organisms; the energy which the second class of organisms would use thus goes to aid in the development of the more resistant forms. The growth of denitrifying bacteria was retarded through the presence of the antiseptics, although there was ultimately a small increase in total production. Denitrification, it is claimed, plays no important rôle in normal soil where there is no pronounced source of carbon present.

In ordinary soils nitrification was for a time retarded by the application of ether, but later it was considerably increased. The stimulating effect of ether and carbon bisulphid on the growth of plants in sterile soil was demonstrated.

In conclusion the author states that the beneficial effect of the substances tested is due to their stimulating action on the plants themselves as well as the effect they exert on the lower organisms.

An extensive bibliography is appended.

Action of carbon bisulphid on germinability of grain, A. MORETTINI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 5-6, pp. 417-422).—The author conducted a series of experiments to determine the injury to germinability of grain caused by the application of carbon bisulphid vapor for the purpose of combating injurious insects. Two lots of grain were employed, the germinability of which was from 99 to 100 per cent before treatment.

In a series of exposures to the vapor lasting from 1 to 60 days the germination decreased from 92 to 0.5 per cent for one kind of grain, and from 89 to 15 per cent for the second. Smaller quantities of the gas caused less injury. The smallest quantity that was effective as an insecticide was about 31.55 gm. of the poison per hectoliter of grain. This could be continued for 16 days without reducing the germinability below 98 per cent, and after 100 days it was not below 95 per cent. About 35.9 gm. per hectoliter is considered a safe proportion to employ for a period necessary to protect the grain.

The action of carbon bisulphid on the germination of wheat, P. FANTECHI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 7, pp. 515, 516).—Attention is called to experiments made by the author in 1900 upon the effect of carbon bisulphid on the germinability of wheat. He claims to have found that the vapor of carbon bisulphid as commonly used to destroy insects in stored grain did not

affect the germinative faculty of the grain. When seed were immersed for 2 seconds in carbon bisulphid and afterwards placed in the air, the germination of about 10 per cent was destroyed. Immersing seed for a minute and allowing them to remain in a vapor of carbon bisulphid for 24 hours destroyed about half of the seed. The action of the vapor was found to be greatly influenced by temperature, 30° C. causing a depreciation of at least 50 per cent in germination, and at 40° all seed were destroyed.

**Treatment of seeds with hydrogen peroxid**, E. MIÈGE (*Gard. Chron.*, 3. ser., 50 (1911), No. 1292, p. 241; *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, p. 2600).—A brief account is given of investigations which show that dilute solutions of hydrogen peroxid facilitated germination and stimulated the active development of plants.

The author concludes from his experiments that hydrogen peroxid is a useful fungicide for treating seed affected by smut. Immersion of infected seed for 15 minutes in a 1 per cent solution is said to have not only destroyed the adhering fungus spores but to have also protected seedlings against subsequent attack. It is thought that this fungicide might be efficient for the control of hollyhock rust.

**Hydrocyanic acid formation in germination of seeds**, C. RAVENNA and C. VECCHI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), II, No. 9, pp. 491-495).—This investigation follows up work previously noted (*E. S. R.*, 24, p. 229), experiments being carried on with seeds of flax and sorghum.

In flax seeds which normally contain a minute quantity of hydrocyanic acid the proportion was considerably increased on germination, and this increase was augmented upon the addition of 0.1 per cent of chlorid of ammonia to the water with which the seeds were moistened. In experiments with sorghum seeds, which in the quiescent state contain no prussic acid, this acid was produced by germination, and as before, its amount was augmented by the addition of sal ammoniac. In one experiment the addition of glucose (0.2 per cent) gave a greater percentage of this acid than did sal ammoniac, while a still greater proportion was obtained by employment of both together in the percentages above mentioned.

**Investigations on the germination of seeds of some weeds**, O. MUNERATI and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 1, pp. 40-50).—The effect of chemical and mechanical means of rendering seed coats of seed permeable was investigated. Different lots of seed of a number of common weeds were either immersed in strong sulphuric acid (specific gravity 1.84) or punctured with a needle opposite the embryo.

Among the so-called refractory seeds, soaking for from 15 to 90 minutes in sulphuric acid or puncturing the seed rendered the seed coats more permeable to water and hastened germination, though in some cases the total germinations of the untreated seed were the greatest. For the seed having thinner seed coats considerable injury followed the treatments. In a number of instances the germination of old seed was higher when treated with sulphuric acid than in the case of untreated lots.

**Dependence of the respiration of plants on the lipoids**, E. STANEVICH (*Trudy Imp. S. Peterb. Obshch. Estestro. (Trav. Soc. Imp. Nat. St. Petersb.)*, 41 (1910), pp. 17-33; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 12 (1911), No. 1, p. 110).—The author examined the respiration of wheat germs after extraction with various solvents (*E. S. R.*, 25, p. 124). The quantities of carbon dioxide given off by 3 gm. of the embryos in 9 hours after the extractions were as follows: Control 163 mg., extracted with toluene 81.8 mg., acetone 79.8 mg., chloroform 61.4 mg., ether 43.0 mg., and alcohol 6.3 mg.,

showing a close relation between the extracted lipoids and the amount of carbon dioxide set free.

The fermentation of "hefanol" is more depressed by alcohol than by acetone.

Some recent investigations on the formation of starch in plant cells, A. GUILLIERMOND (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 7, pp. 276-279, figs. 9).—It is claimed that a study of starch formation in potatoes, in the roots of *Phajus grandifolius*, and in other plants indicates a mitochondrial origin and that the leucoplasts of Schimper are identical with the chondriosomes of animals. Further studies are claimed to show that in plants starch is a direct result of the activity of the chondriosomes.

Glycogen in phanerogams and its relation to oxalate of lime, J. POLITIS (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), II, No. 8, pp. 431-439).—Studies were made on *Orchis morio*, *Bletia hyacinthina*, *Pitcairnia xanthocalyx*, and *Billbergia nutans*.

The author found glycogen to exist in several phanerogams, as well as in the few cryptogams in which it is asserted to be confined. The mucilage of the tubers of *Orchis* is asserted to be composed chiefly of glycogen. In the phanerogams examined by him glycogen was formed only in the cells containing oxalate of lime in the form of raphides, from which fact he infers some relation existing between the carbohydrate and the salt in question.

Origin and office of oxalate of lime in plants, J. POLITIS (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), II, No. 9, pp. 528-534).—This article, after summing up the conclusions of various other investigators bearing upon these points, gives the conclusions drawn from the author's own work briefly as follows: Oxalic acid, with its resulting calcium oxalate, has its origin in the cell in which the salt is found in crystalline form, and the acid is formed by oxidation of glycogen or amyloids.

The views of various others as to the office of the salt are given.

Essential oils and other volatile plant products as the cause of sap movements, I. GIGLIOLI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), II, No. 8, pp. 349-361; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 591, II, p. 79).—These investigations appear to be one phase of a more general study by the author of water movement in living tissues. Besides giving consideration to the work and reports of some others in the same field, he presents the results of his own researches with various volatile substances in regard to their influence on movement of water in the case of fruits, potatoes, fresh wood, etc.

It was found that in several cases, notably that of cactus in chloroform vapor, the movement of water from the plant and presumably through its interior tissue was considerably increased by the presence of a volatile body. The suggestion is made that such products in the plant tissues may be a more or less important modifying factor in transpiration and related processes.

Formation of alkaloids in tobacco, C. RAVENNA and V. BABINI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 20 (1911), II, No. 8, pp. 393-398).—This is a report of investigations in close relation to those carried on by G. Ciamician and C. Ravenna (*E. S. R.*, 25, p. 634), M. Treub, and others cited. Tobacco plants in 5 groups were grown in nutritive solutions differing only as to the presence or absence of calcium nitrate (0.1 per cent) and of glucose (2 per cent), and under other conditions alike except as to the admission or exclusion of light.

It was found that the maximum percentage of nicotine in terms of the plant's original weight was obtained by the plant from the solution containing glucose in light; the minimum from the same solution in darkness. The difference is

ascribed to the arrest of the formation of the alkaloid when the plant is grown in darkness.

**Heliotropism in radium illumination**, H. MOLISCH (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 120 (1911), I, No. 4, pp. 305-318, figs. 5; abs. in Ztschr. Bot., 4 (1912), No. 2, p. 151*).—This is a continuation of work taken up several years ago by the author on radium and heliotropism of plants (E. S. R., 17, p. 752) in which only negative results were obtained, owing presumably to weakness of the radium preparation employed.

He now concludes that radium of strong illuminative power exposed at short distances is capable of producing in heliotropically very sensitive plants a positive tropism. This is true of the young seedlings of oats (*Avena sativa*) and vetch (*Vicia sativa*), but barley (*Hordeum vulgare*) and sunflower (*Helianthus annuus*) are not sufficiently sensitive to respond to radium illumination so far as tried. The  $\alpha$ ,  $\beta$ , and  $\gamma$  rays seem to check the longitudinal growth of the plants, also to shorten the period of spontaneous nutation, limit the synthesis of anthocyanin, and in some cases produce other injurious effects on plants which are very sensitive to its action.

**Investigations on Mucorineæ and their relations to soil**, O. HAGEM (*Vidensk. Selsk. Skr. [Christiania], Math. Naturw. Kl., 1910, No. 4, pp. 152; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 11-12, pp. 2475-2477*).—Studies by the author and others have shown about 30 species of Mucorineæ present in the soil and that they constitute an important element in the fungus flora of soils. Most of the species identified belong to the genera *Mucor*, *Absidia*, and *Zygorhynchus*. The distribution of the species seems to vary with different soils, those in cultivated soils differing from the species present in the soil of coniferous woods. While the relation of the Mucorineæ to mycorrhiza has not been established, it appears that there is a close relationship between the species present in the soil and those found occurring as mycorrhiza on roots. Both obligate and facultative parasites are found among these soil molds, but in most soils the facultative parasites predominate. Some species seem to be obligate parasites on higher fungi, as the agarics, and most of these belong to the genera *Spinellus*, *Dicranophora*, and *Sporochinia*.

The nitrogen, carbon dioxide, acid, and temperature relations of the different groups were studied. Only a few species were found to have any considerable effect on the nitrogen balance of soils through their action on nitrites and nitrates. Their importance, so far as the nitrogen balance is concerned, depends on the transformation of the ammoniacal nitrogen into a stable form which is useless to higher plants. The amine and amidic nitrogen of the various organic substances in the soil is transformed by some of the species into ammoniacal nitrogen, a part of which is transferred into stable forms, while the other part circulates through the soil and can be utilized by higher plants.

The investigations showed that the Mucorineæ in general, and especially the soil forms, could not attack many carbon compounds, particularly cellulose and hemicellulose, although they could change various saccharin and pectin substances.

The temperature limits for the growth of most species lie between 7 and 33° C., with optima of from 20 to 25°.

An extended bibliography is given.

**The slime or gum of *Rhizobium leguminosarum***, R. GREIG-SMITH (*Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 21-24, pp. 552-556, fig. 1*).—This is a short account of work, the results of which were previously published elsewhere (E. S. R., 18, p. 1031). The author here describes briefly his methods of obtain-

ing and examining the gums and records some results which may be stated in substance as follows:

Five gums were obtained from five morphologically similar bacteria. They produced the same gums from sugar. There appears to be a probability that the plant tissues utilize the gum for building up their nucleoprotein. The location of the bacteria in the plant appears to have a distinct bearing upon their physiological activity. The optimum quantity of saline matter required for formation of slime is small, from 0.1 per cent to 0.2 per cent, approximating that found in soil water. *Rhizobium* is capable of fixing atmospheric nitrogen under conditions that favor slime formation, and between these two processes there appears to exist a somewhat regular quantitative relation.

The author was not able to confirm the view previously advanced by him that *Rhizobium* is a yeast. It appears to be a compound bacterium and consists of cocci contained in a straight or branching, tubular capsule. The cocci divide both transversely and longitudinally and the capsule, consequently, assumes sometimes a  $\gamma$  or Y form. The majority of the bacteria in a nodule are found to be dead.

### FIELD CROPS.

[Field crops at the Hawaii Station], W. P. KELLEY, E. V. WILCOX, and C. K. McCLELLAND (*Hawaii Sta. Rpt. 1911, pp. 9, 51-63, pls. 2*).—Earlier field crop work at this station has already been noted (E. S. R., 25, p. 328).

Cooperative fertilizer experiments with taro indicate "that this plant, like rice, is benefited by allowing the soil to dry out and become aerated between crops, by applying all of the fertilizer before planting rather than after planting or in fractional doses, and by using sulphate of ammonia rather than nitrate of soda as a source of nitrogen.

At Kunia and Waipahu applications of (1) dried blood, superphosphate, sulphate of potash, and lime, and (2) dried blood, dicalcic phosphate, and sulphate of potash were followed by higher average cotton yields during 1909-10 than were secured from the same components and nitrate of soda, ammonium sulphate, and basic slag in various mixtures. The fertilizers were so applied as to supply 20 lbs. of nitrogen, 50 lbs. of phosphoric acid, and 30 lbs. of potash per acre. From the data presented the author concludes that the soil is most in need of phosphates and that dicalcic phosphate appears more effective than other forms. Potash and nitrogen produced little effect unless applied with phosphates. Lime applied alone appeared ineffective.

When 2 crops of rice per year were grown the yields gradually decreased if fertilizer was applied to the spring crop only, but were maintained when ammonium sulphate was applied to each crop before planting. The superiority of the sulphate to nitrate of soda has been previously noted (E. S. R., 26, p. 41).

In a test of rice varieties newly imported from Japan the average yields from the spring crop of 1910 ranged in the following order: Omachi, Shinriki, No. 153 (old variety), Benkei, and Miyako, and tests in the fall of 1910 and spring of 1911 were in general conformity. Only Miyako was produced in sufficient quantity for a culinary test, and this is said to cook as well as imported Japanese rice and to hold its moisture as the Hawaiian rice does not. In taste and appearance, but not in oily strength, it is said to equal the native Japan rice. Two variations were noted in the growth of these rices. Benkei developed a heavy tillering habit which Shinriki appears to have lost, and Omachi, a bearded rice, became almost entirely beardless. If Omachi does not deteriorate it is believed to be the rice to grow in Hawaii.

In a cooperative test of cotton variation at Waipahu the following lint yields per acre were secured: Chinese upland 180.83, Egyptian 115, Sea Island 54.66, and Caravonica 25.37 lbs. The location appeared unfavorable, as only about 40 per cent of a stand was reported and the bollworm took about 30 per cent of that. The damage to the upland cotton was less than that suffered by the other varieties. In another test transplanted Caravonica seedlings gave better results than those not transplanted.

At the station Caravonica cotton yielded at the rate of 165.9 lbs. of lint per acre and produced fibers ranging from  $1\frac{1}{8}$  to  $1\frac{1}{2}$  in. in length. A brief progress report is given of date of pruning and pinching back tests, together with a statement of the theory on which these tests were conducted. The cotton was picked as it matured from the branches that had been pruned. Strength tests of the fibers showed that they had decreased from 8.99 gm. to 6.24 gm. in breaking strength. The more immature the fiber at pruning time the lower its breaking strength when tested. Individual plants yielded from 0.33 to 2.73 lbs. of lint per plant.

The use of a lantern placed above a pan of water and kerosene in the field at night and the regular cutting off and burning of infested bolls reduced the percentage of bollworm infestation from 68 per cent at the first picking to 50 per cent at the second and 26 per cent at the third picking.

Sea Island cotton yielded at the rate of 395 lbs. of lint per acre and produced fibers ranging from  $1\frac{1}{2}$  to  $1\frac{1}{8}$  in. in length in spite of a 20 per cent loss due to insects. Poisoned bran placed in small circles about the hills prevented damage from cutworms.

On December 31 the plants were pruned back to stumps, some high and some low. The growth invariably appeared near the ground, indicating that Sea Island cotton grown as a perennial should be pruned low.

Immature fiber picked from plants that had been pulled was found to contain a large amount of nep, immature fiber, and excessive waste. The yarn was too weak for thread.

A number of crops were planted for the purpose of determining their profitability in Hawaii. Peanuts did well and were in one case planted between cotton rows. Broom corn yielded at the rate of from 95.4 to 501.6 lbs. of brush per acre. Other crops tested were corn, saccharin and nonsaccharin sorghums, and a new legume called guar.

[Rotation and fertilizer tests], H. J. EUSTACE and V. M. SHOESMITH (*Michigan Sta. Rpt. 1911, pp. 183, 184; 212-221*).—This is mainly a report of tests begun in 1891.

During the first 5 years all plats were uniformly cropped to determine their relative fertility. Tables present data from which the author concludes that aside from the matter of profit a wheat-clover rotation is somewhat better in effect on soil fertility than a wheat-clover-corn or a wheat-clover-potato rotation, but the differences are not marked. Plats which had been continuously planted to wheat and corn were inferior in producing power to those on which clover had been grown in rotation. Beans grown each season with rye seeded in the fall and turned under in the spring were followed by 21 per cent greater yields than a continuous cultivation of corn and 29 per cent greater than was secured from the plat planted continuously to wheat. Continued cropping to orchard grass was followed by a 21 per cent greater yield than was a wheat-clover rotation. This is attributed to the heavy root system and the plant food which it stored.

In one series plats fallowed for 10 years produced more than any others of the series except those seeded to orchard grass, but when the averages of 2 series were considered fallow was excelled by a wheat-clover rotation.

A second portion of this long period experiment was devoted to tests of commercial fertilizer. The plats were planted in uniform croppings from 1891 to 1898. Tables state in detail the yields secured during 1899-1905. During this period stable manure, acid phosphate, nitrate of soda, muriate of potash, and a mixed commercial fertilizer were tested singly and in various mixtures for beets, potatoes, corn, oats, wheat, beans and turnips, but no conclusions are drawn.

The horticulturist reports better potato yields following a mixture of 194 lbs. of nitrate of soda, 257 lbs. dried blood, 1,000 lbs. of acid phosphate, 400 lbs. of sulphate of potash, and 49 lbs. of filler applied at the rate of 500 lbs. per acre than were secured from the use of a complete potato fertilizer or a mixture of 570 lbs. of dried blood, 1,000 lbs. of acid phosphate, 400 lbs. sulphate of potash, and 30 lbs. of filler.

Cooperative grain investigations at McPherson, Kans., 1904-1909, V. L. CORY (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 240, pp. 22*).—This is a report of work carried on in cooperation with the Kansas Station.

Among the winter wheat varieties tested Turkey, Kharkof, and Crimean produced the highest 4-year-average yields, 25.9, 24.53, and 23.88 bu. per acre, respectively. Three varieties planted about the middle of September, 1905, gave an average yield of 7.78 bu. per acre as compared with 20.46 bu. secured from the same varieties planted about a month later.

Among barley varieties tested Caucasian, Yenidje, and Odessa produced the highest 4-year average yields, 30.32, 28.57, and 28 bu. per acre, respectively. Among varieties of oats tested Sixty Day and Seventy-five Day gave 4-year average yields of 37.56 and 36.54 bu. per acre, respectively. Among the other grains tested Proso proved a failure in all trials, but a few varieties of non-irrigated rices were promising. Kubanka wheat gave a 4-year average yield of 13.43 bu., Black Winter emmer 52.16 bu., winter einkorn 19.85 bu., spring einkorn 22.8 bu., and Red Winter spelt 46.8 bu. per acre. Each of 3 winter ryes tested yielded 19 bu. or over per acre.

Buckwheat gave fair results, the Sando Soba variety of the Japanese type apparently being the best of the 12 or 15 varieties tested. Chinese buckwheats are hardier and more drought resistant but longer in maturing. Plantings during the third and fourth weeks of April gave better results than those made at earlier or later dates.

The author states that the suspension of seed for 15 minutes in a solution of 1 lb. of formalin to 50 gal. of water will prevent oat smut, the stinking smut of wheat, and the covered smut of barley, but caused no appreciable diminution in the loose smuts of wheat or barley. A modified hot-water treatment used was applied by soaking wheat and barley in cold water for 7 hours and then treating for 15 minutes at 54 and 52° C. respectively, and 10 minutes treatment of oats at 57° without soaking. In the crop following these treatments there was no smut in the oats, no loose smut in the wheat, and in case of the barley only a trace of loose smut in 3 varieties.

Studies of the principal buckwheat species, E. MIÈGE (*Recherches sur les principales espèces de Fagopyrum. Paris, 1910, vol. 1, pp. 426; rev. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 5, pp. 1054, 1055*).—This volume presents a comprehensive study of buckwheat species and varieties. The author gives measurements and 1,000-kernel weights for use in distinguishing the 4 species *Fagopyrum esculentum*, *F. tataricum*, *F. stenocarpa*, and *F. emarginatum*, and for distinguishing 6 varieties of *F. esculentum*. A review of the status of buckwheat growing in the world's agriculture is followed by discussions as to the production and improvement of the crop.

The condition of Kansas seed corn, E. G. SCHAFER (*Kansas Sta. Circ.* 22, pp. 3).—After a long dry period in the summer of 1911 more favorable conditions came in the fall. Corn renewed its growth and at the time of the early freezes contained a high percentage of moisture. Among thousands of ears of seed corn received from farmers in different parts of Kansas, the station's average test has been "about 75 per cent good." In view of these facts this circular gives suggestions on the purchase of seed corn, the germination test, the individual ear test, and the preparation of land for planting.

The seed corn situation, C. G. WILLIAMS (*Ohio Sta. Circ.* 121, pp. 117-120).—A discussion of the advantages of testing is followed by directions for the use of the germination test of seed corn.

Some data for oat growers, L. C. BURNETT (*Iowa Sta. Bul.* 128, pp. 93-127, figs. 5).—Earlier oat experiments have already been noted (E. S. R., 19, p. 1034).

A key to oat varieties based upon the work of J. B. Norton and a classification of oats for shows precede tables reporting the results of tests of 48 commercial oat varieties as to date of ripening, height, percentage of lodging, the yield per acre, and the weight per bushel during 1908, 1909, and 1910. Averages for this period, for the 5-year period 1906-1910, and the 7-year period 1904-1910 are given where possible. Among 7 common Iowa varieties, Kherson gave a 7-years' average yield of 55.9 bu. per acre, or 7.5 bu. more than the average of the standard varieties, and was excelled in early ripening qualities only by the Early Champion and White Alaska. Silver Mine averaged 52.3 bu. per acre but averaged about 8 days later in ripening.

Iowa's 1907 oat crop showed very light weight per bushel and yield. The heaviest and best seed obtainable of 20 leading varieties was purchased from outside sources for comparison with the light home-grown seed during 1908. The average results are indicated by the following figures, the data for the home-grown seed being stated first: Weight of seed per bushel as sown 25½ and 33 lbs., number of seeds sown per acre 2,443,000 and 1,829,000, leaf-rust 16.7 and 18.9 per cent, stem rust 26.7 and 26.8 per cent, lodging 11 and 16 per cent, yield per acre 31.2 and 31.5 bu., weight of crop per bushel 22.1 and 22.2 lbs. The average date of sowing was April 19, and the average date of ripening July 25. All plats were sown at the rate of 3 bu. per acre. In case of 12 varieties the light acclimated seed outyielded the heavy imported seed, in 7 cases the heavy seed outyielded the light, and in one case the yields were equal. "Some of the plats with heavy seed may have been underseeded. The figures tend to show that the heavy seed and light seed were about equal pound for pound, but not seed for seed, nor measure for measure."

Six bu. of Kherson and Silver Mine oats were taken just as they came from the thrashing machine and divided into 4 samples of each variety, a check sample and samples fanned 1, 2, and 3 times each, respectively. Each fanned sample was again divided and used in sowing so that each of 4 plats of each variety received the same number of pounds of seed, while other plats were given the same number of seeds, as nearly as the drill could be calibrated to accomplish this result. In 9 different tests the unfanned oats never excelled the fanned samples in yield, but the samples fanned 3 times rarely yielded more than those fanned once or twice.

A Wyoming-grown sample of oats of Irish Victor stock, which won the championship at the Portland Exposition, was sown in 1907 and 3 succeeding years for comparison with other Irish Victor seed. In the 4 years it never equaled the parent stock, but approached it at a rate which if continued in the future would make it equal the older stock within 2 more seasons. In 1907 new varieties were purchased, which showed such variations that the seed of each variety

was retained each season for further sowing as a separate variety, for example, Probesteier 1907, Probesteier 1908, etc., indicating the first season in which the variety was grown at Ames from the stock so designated. Tables present the economic portion of the notes taken on this test of seed of different degrees of acclimatization. Another table compares the first, second, and third crops after importation of the seed obtained from the British Isles and various stations. The author notes that the British seed, the normal date of ripening of which is late in August was damaged less and less in each succeeding generation by the changed conditions, consequently the second crop exceeded the first and was exceeded by the third in yield. Seed from central Illinois yielded 52.6, 52.7, and 52.2 bu. per acre for the 3 crops. The small rise in the second crop is so frequent as to be important, in the author's opinion, although its frequency is less than 50 per cent. He concludes that "short-seasoned territories produce oats better adapted to a longer-seasoned territory than the ones usually grown there," but that "as a whole the imported seed is not better than the average home-grown seed."

Although the seed sold under a given name does not conform to a single type of plant, or always contain a limited number of types in the same proportion, it is stated that "at the Iowa Station it is not considered that this point seriously affects yield or weight per bushel." In 1910 only 4 of 19 new importations yielded as well as the same varieties that had been acclimated for 1 or 2 years. The loss in yielding power appeared to be directly proportional to the degree of change of environment. The increase in yield was most marked in the second crop, and quality of seed appeared less important than acclimatization. Where importations appeared successful the increase arose from securing a better adapted variety rather than from the quality of seed.

In 4 years' tests drilling and broadcasting gave average yields of 40.7 and 36.9 bu. per acre, respectively, and wherever the land is dry enough to permit, drilling is recommended.

A table states the results of a 6-years' test of rates of seeding Kherson and Silver Mine oats. During the 4-year period 1908-1911 Kherson yielded more heavily after seeding at the rate of  $4\frac{1}{2}$  bu. per acre than at any lighter rate, but Silver Mine sown at the rate of 4 bu. per acre yielded much more heavily than any higher or lower rate tested.

The Chicago grades of oats are stated and suggestions made as to needed improvements in methods of oat production in Iowa.

Composition of oats as affected by fertilization, hilling, and rate of seeding, W. EBERT (*Mitt. Landw. Inst. Leipzig, 1911, No. 10, pp. 3-88*).—The author reviews the literature of the subject, with frequent citations and a bibliography of 123 titles, and from a considerable amount of data, gathered in his own tests, he draws the following conclusions:

Variation in rate of sowing influences the composition of oats more than does variation in any other cultural practice tested. Thin sowing increases root development, tillering, length of panicle, number of spikelets, and weight per panicle and per 1,000 kernels, and reduces the chaff percentage. Both grain and straw are increased in dry substance and protein content, the chaff is increased in dry substance and varies in protein content, and ether extract and crude fiber decrease.

Fertilization showed the next greatest influence, producing an increased root development, tillering power, length of straw, length and weight of internode, length and weight of panicle, number of spikelets, and whorls, and 1,000-kernel weight, and reducing the chaff percentage. It apparently increased the protein

content of straw and chaff and the dry matter content of the grain, but reduced the ether extract and crude fiber in the grain.

Hilling increased root development, but gave no corresponding increase of tillering power. It increased the weight per haulm and per internode, but showed varying results as to length of both. With some exceptions it lengthened the panicle and the number of whorls. It increased the 1,000-kernel weight, chaff percentage, crude fiber of the grain, and the protein percentage of the straw. As the hilled plats fell below the unhilled in both gross and net income, the author concludes that hilling is valueless, but notes that these results may be attributed to the fact that the condition of the soil prevented hilling at the proper time.

**Rice**—A possible new industry for California, G. W. SHAW and A. J. GAUMNITZ (*California Sta. Circ. 7*), pp. 26, figs. 7).—This circular reports studies made in order that inquiries as to the possibility of developing the rice industry in California might be intelligently answered. General discussions of rice culture and its soil requirements and directions for the production of the crop are followed by tables and descriptive text stating the results of variety and irrigation tests on a number of California farms.

Analyses of water from a spot where rice was growing satisfactorily and from another where it appeared to be seriously affected by the alkali gave the following results, the first percentage in each case being that for the water which was apparently producing injurious effects: Total soluble salts, 0.6896 and 0.0912; chlorids, 0.1160 and 0.035; carbonates, 0.1017 and 0.0042; and sulphates, 0.4719 and 0.052 per cent.

In a depth of water test the ground was kept thoroughly wet from April 1 to May 10. Water was then kept 1 in. deep from May 11 to May 24, and varied in depth from 1 to 6 in. on different areas from May 25 to August 27. From the data reported the author concludes that "the indications are quite strong that the maximum quantity of water on the adobe soil should not exceed 4 in. in depth and that not less than 2 in. should be used."

Analyses made by B. A. Madson showed the composition of composite samples of California-grown rice of the Japanese and Honduras types to be, respectively, water 9.62 and 9.72, protein 10.96 and 11.4, fat 2.57 and 2.51, ash 1.9 and 1.61, crude fiber 1.24 and 1.17, and carbohydrates 84.23 and 83.31 per cent. It is concluded that the food value of the California-grown sample is as high as that of the southern-grown product.

Other tables state the amount of plant food removed by wheat and rice, the labor cost of growing rice in various counties, and the duty of centrifugal pumps for lifting irrigating water less than 35 ft.

In a variety test at Biggs in 1909 an average yield of 3,486 lbs. per acre was secured from plats varying in size from one-fortieth to one-tenth of an acre. In 1910 an average yield of 7,089 lbs. per acre was secured from small plantings, while an average yield of 3,820 lbs. per acre was secured from another series of plats ranging from 0.25 to 13.51 acres in size.

"From all data obtainable it appears that California may ultimately be producing large quantities of this valuable food product." The authors regard the outlook for the industry as exceedingly encouraging, but state that this publication "distinctly does not wish to urge engaging in the industry in a large way until more is learned concerning it."

**Soy beans as a supplementary silage crop.** E. R. MINNS (*New York Cornell Sta. Bul. 310*, pp. 259-274, figs. 6).—Directions for growing soy beans in New York are followed by reports of the results of tests, mainly conducted by farmers, some of whom cooperated with the experiment station in their test.

On a farm at Milbrook, N. Y., 4 acres of a planting of 4 kernels of corn and 6 soy beans per hill planted by hand in hills 36 by 40 in. apart yielded in 1905 72 tons of fodder. The ratio of corn fodder to soy-bean fodder, by weight, in the mixture was estimated at 5:1. The next year a mixture of 4 or 5 grains of corn to 10 or 12 soy beans per hill gave a crop in which the ratio was slightly less. During the following March the silage contained 4.22 per cent of protein and 2.2 per cent crude fat. During 1907 corn made a poor growth and the proportion of corn to soy-bean fodder based on the weight of 12 hills was 2:1. The silage showed higher percentages of solids, protein, fat, and carbohydrates than did ordinary corn silage, and its nutritive ratio was 1:6.75.

During the next 2 years hand planting was supplanted by mixing the beans and corn in equal quantities, and sowing with a grain drill at the rate of 20 qts. of the mixture per acre in rows  $3\frac{1}{2}$  ft. apart. Although droughts interfered in 1911, 12 $\frac{1}{2}$  tons of fodder per acre were secured from a field below the average in productiveness. In the same neighborhood another farmer planted 16 acres in 15 hours with a corn planter which dropped from 4 to 6 kernels of corn and from 8 to 10 beans in the same hill from separate boxes and also distributed fertilizer. A yield of from 12 to 15 tons per acre followed this planting.

In another case every third row was devoted entirely to beans and the binder was driven across the rows containing only beans. Of the mixture, 19 per cent was soy beans as compared with 11 $\frac{1}{2}$  per cent from the rows which had been planted at the rate of 5 or 6 kernels of corn and from 8 to 12 beans per hill.

A few farmers reported the hand planting of soy beans between corn hills or very close to them "crosswise of the first cultivation." Frequently the beans failed because of dry weather, or the advancement of the corn, and the plan succeeded only under favorable conditions. Cooperative tests of mixed plantings in 3 localities in 1908, 5 in 1909, and 4 in 1910 are reported showing an apparent decrease in the growth of corn due to the mixture, but no conclusions are drawn. In 3 years' tests of mixed planting at the University farm, corn alone gave a slightly higher total yield per acre, but analyses showed a lower percentage of protein and other extract than did the mixed fodder.

Although the author states that he "has failed to prove the real value of soy beans grown in corn fields for silage in the experiments just described," he presents statements from a number of farmers, some of whom have practiced such mixed planting and appear to regard it as decidedly advantageous.

**Report on field trials with varieties of swedes in the year 1910, E. HARRISON and E. E. STOKES (*Midland Agr. and Dairy Col. Bul. 6, 1910-11, pp. 35-41*).**—This is a report of a variety test of swedes conducted during 1910, including data as to the yield and dry matter percentages of the varieties tested in 5 different localities. In amount of dry matter produced per acre, Golden Melon stood first, Magnum Bonum second, and Extra Improved Purple Top third.

**The adulteration and misbranding of the seeds of red clover, Kentucky blue grass, orchard grass, and hairy vetch, B. T. GALLOWAY (*U. S. Dept. Agr., Office Secretary Circ. 39, pp. 7*).**—In continuation of the seed inspection of 1910 (*E. S. R., 25, p. 237*), 1,548 samples of seed were examined in 1911, of which 250 were found to be adulterated or misbranded.

Of 305 samples obtained as orchard grass, 28 were adulterated with the seed of meadow fescue, rye grass, or other seeds. Of 430 samples obtained as Kentucky blue grass, 35 were wholly or in part the seed of Canada blue grass or other grasses. None of the 510 samples of red clover seed secured were found to be adulterated or misbranded. Of 303 samples secured as hairy or sand vetch, 187 were found to be adulterated or misbranded. 5 were spring vetch

and contained no hairy vetch seed, while others contained varying amounts of spring and other vetches. Most of the hairy vetch seed used in the United States is imported, but an examination of the seed-producing region of Germany and the Baltic Provinces of Russia does not indicate that hairy vetch is harvested with the seed of the cultivated forms of spring vetch.

Seed tests made at the station during 1911, G. T. FRENCH (*New York State Sta. Bul.* 345, pp. 42-58).—A continuation of the tests made at this station during 1910 (E. S. R., 24, p. 736), including 548 alfalfa, 253 red clover, 98 timothy, 86 alsike, and 30 miscellaneous seed samples.

Dodder occurred in 12.9 per cent of the alfalfa samples, and in 4.74 per cent of the red clover samples. Large seeded dodder occurred in twice as many samples as did small seeded dodder. Noxious weed seed was a little more frequent in occurrence in red and alsike clover than in 1910. Observations indicated that several cases of alsike adulteration with yellow trefoil resulted from the presence of trefoil in the field. *Centaurea repens* was again found in several alfalfa seed samples, indicating the importation of seed. Russian thistle and roquette continued to attract attention in alfalfa fields but without indication of being dangerous.

Chemical tests of 4 samples of sulphur-bleached oats indicated the presence of sulphuric acid in large quantities, while germination tests showed none viable in 2 cases, 14 per cent in 1 case and 1 per cent in another.

Quality of farm seeds in 1911, F. H. HALL (*New York State Sta. Bul.* 345, popular ed., pp. 1).—This is a popular edition of the above.

Methods of keeping crop records at the Michigan Station, F. A. SPRAGG (*Michigan Sta. Rpt.* 1911, pp. 193-211, figs. 15).—This is a paper presented at the November, 1910, meeting of the American Society of Agronomy. It presents blank pages from an accession number book, oat and alfalfa breeding registers, and individual alfalfa and clover registers. The keeping of records and the use of stakes, labels, platting systems, and progeny numbers are explained.

## HORTICULTURE.

Report of the horticulturist, J. E. HIGGINS (*Hawaii Sta. Rpt.* 1911, pp. 25-42, pls. 5).—Studies of various phases of avocado production were continued during the year. The results have been reported quite fully in a recent bulletin of the station (E. S. R., 26, p. 441).

The papaya investigations were continued, the work including breeding, pruning, thinning, and shipping experiments. It has been found possible to propagate papayas by using monoecious trees without the help of sterile male trees (E. S. R., 25, p. 337). A number of successful crosses are here discussed. Perfect monoecious flowers have been successfully self-fertilized and pollen from such flowers was successfully used on pistillate dioecious flowers and on perfect or hermaphrodite flowers occurring on staminate dioecious trees. The latter flowers can also be fertilized by their own pollen and by the pollen from staminate flowers on similar trees. The pollen of staminate monoecious flowers applied to pistillate dioecious flowers has thus far proved unsuccessful. The breeding work will be continued to perpetuate, if possible, the monoecious character of certain members of the first generation seedlings and at the same time combine with this character desirable characters of the dioecious papaya.

One papaya tree growing on the station grounds was devoid of seeds in all the fruits examined. Some of the flowers were hand pollinated with pollen from staminate flowers of the dioecious type, others were sealed in paraffin sacks several days before opening to prevent pollination by natural means. All of the flowers developed full grown papayas. Similar results were secured

with protected flowers on some other trees, the resulting fruit in addition to being seedless was somewhat smaller than the fruits from fertilized ovaries. These results as a whole lead to the conclusion that pollination is not always necessary for the production of fruit in the papaya and that seedlessness in case of the first noted tree, at least, is probably not due to a lack of pollination.

Pruning experiments with the papaya indicate that larger sized fruit is secured by removing the branches and encouraging fruit production along the main trunk. Thinning the fruit on certain trees which tend to overbear was likewise of considerable value. Recent trial shipments of papayas to San Francisco indicate that, with proper attention to selection of varieties possessing shipping qualities and to careful handling and packing, papayas may be successfully marketed in the United States as soon as a demand is created for the fruit.

Considerable trouble has been experienced with the Bluefields banana in Hawaii because the pseudostems break off and let the bunches fall. This appears to be due to a number of contributory causes, such as close planting and lack of pruning, thereby promoting weak stem growth. Furthermore, the bunches are allowed to remain on the plants until they become too heavy. In order to lessen decay in transit, bananas grown for export should be removed from the plant some time before the bunch has attained its full growth. The so-called Hamakua banana regarded by some as identical with Bluefields was determined as distinct from Bluefields but resembling it sufficiently to be marketed as Bluefields.

With the exception of spraying experiments (E. S. R., 26, p. 441) little new work has been undertaken with mangoes. One of the new varieties to come into bearing, the Brindabani, appears to be valuable for its heavy and early bearing habits. It has borne mature fruit 18 months after being grafted. The Brindabani and the Oahu, a large fine mango bearing fruit of good quality, are described. The method of making fruit models used at the station as a means of record in the study of mango varieties is here described in detail.

The citrus orchards have been extended somewhat during the year. A list is given of the citrus varieties now growing on the station grounds, together with information relative to accessions and distributions and a note on propagating hibiscus.

**Report of the South Haven substation, F. W. WILKEN** (*Michigan Sta. Rpt.*, 1911, pp. 184-186).—A brief report for the year ended June 30, 1911.

Variety tests of strawberries have been discontinued because the soil on the station property is not considered desirable for strawberry culture. Extensive tests of the comparative value of Bordeaux mixture, self-boiled lime-sulphur, and commercial diluted lime-sulphur on apple, peach, pear, plum, and cherry trees were started in the spring of 1911. In order to make extensive tests of lime-sulphur as a summer spray, the usual Bordeaux mixture was replaced in the general spraying by a concentrated commercial preparation, used at the rate of 1 gal. to 49 gal. of water to which was added 2 lbs. of arsenate of lead. This mixture as used on some 400 varieties of tree and small fruits, but not including strawberries, was satisfactory.

Scab on the Flemish Beauty pear and rot on the Victoria plum, which has not been successfully checked by Bordeaux mixture in previous years, were almost entirely controlled by lime-sulphur. Grape black rot was not well controlled by lime-sulphur nor was the foliage helped. Lime-sulphur at the rate of 1 gal. to 74 gal. of water was satisfactory in preventing plum rot. It can be used nearer to the picking time than Bordeaux since the stain does not show on the fruit.

A list is given of new or little known varieties of apples which produced good crops. Of these Winter Banana and Fameuse Sucre have proved of special merit.

The horticultural industries in Germany (*Gartenflora*, 60 (1911), Nos. 19, pp. 409-426; 22, pp. 491-499; 24, pp. 522-527).—A statistical review of the private, communal, and commercial horticultural industries in the various provinces of Germany.

List of secretaries of state and other horticultural societies (*Rpt. Va. State Hort. Soc.*, 16 (1911), pp. 326, 327).—This list, which includes the secretaries of state and other horticultural societies in the United States and Canada, has been compiled under the direction of the Minnesota State Horticultural Society and corrected to the end of 1911.

The profitable culture of vegetables, T. SMITH (*London, New York, California*, 1911, pp. XV+452, figs. 172).—A handbook for the market gardener and others dealing with both ordinary and French gardening methods.

List of publications important to fruit growers, J. P. STEWART (*Penn. Dept. Agr. Bul.* 215, 1911, pp. 33).—This list is prepared primarily to meet the needs of those actively engaged in fruit growing. It is based largely upon recent publications of various agricultural experiment stations and of the U. S. Department of Agriculture and also includes important books, periodicals, reports of horticultural organizations, etc.

The arrangement is both by topics relating to various phases of orcharding and by specific kinds of fruits.

[Orchard cover crops], H. J. EUSTACE (*Michigan Sta. Rpt.* 1911, pp. 181, 182).—In some cover crop and fertilizer tests being conducted by the Michigan Station in a number of vineyards and orchards, winter vetch sown about August at the rate of from 25 to 30 lbs. per acre has thus far proved the most satisfactory.

Profitable crops for the young orchard, H. L. PRICE (*Rpt. Va. State Hort. Soc.*, 16 (1911), pp. 181-195).—A discussion of orchard cropping practices in Virginia, including a summary of data secured relative to this subject.

Methods and implements in orchard cultivation, H. A. SURFACE (*Rpt. Va. State Hort. Soc.*, 16 (1911), pp. 33-53, pl. 1).—A paper on this subject with the discussion following.

Spraying practice for orchard and garden, S. A. BEACH (*Iowa Sta. Bul.* 127, pp. 49-86, figs. 9).—This bulletin describes methods of combating the more common insect pests and plant diseases which infest Iowa orchards and gardens, special attention being given to the apple. The directions have been prepared to conform with the present knowledge of spraying, being based both on the work of scientific investigators and the experience of practical fruit growers.

The present status of varieties in commercial orchards, A. W. DRINKARD, Jr. (*Rpt. Va. State Hort. Soc.*, 16 (1911), pp. 110-120, pls. 2).—This article summarizes the data relative to varieties secured by the author in connection with an orchard survey of Virginia, a full report of which is to appear later.

Tabular data are given showing the relative rank of varieties in commercial orchards, and comparing the leading varieties in bearing orchards, young orchards, and prospective orchards. York holds first rank in all classes of orchards, both as regards the number of orchards in which it is found and also the number of trees planted. Winesap holds second place in the bearing orchards, and third place in the young orchards and in the prospective orchards. Although Ben Davis is third in the bearing orchards, it is only eighth in the young orchards and ninth in the prospective orchards. The other leading varieties are Albemarle, Stayman Winesap, Mammoth Black Twig, Grimes, Rome, and Black Ben Davis.

On vegetable forcing with special reference to the etherization of strawberries, G. BULTEL (*Jour. Soc. Nat. Hort. France*, 4. ser., 13 (1912), Apr., pp. 212-217).—In support of his previous investigations (E. S. R., 19, p. 144), the author found in tests conducted in 1911 that strawberry plants submitted to ether vapor came into bearing about 2 weeks earlier than untreated plants.

Grape stocks best suited for dry and limy soils, N. GARCÍA DE LOS SALMONES (*Prog. Agr. y Pecuario*, 17 (1911), Nos. 726, pp. 330-332; 727, pp. 346-348; 728, pp. 361-364; 729, pp. 379, 380; 730, p. 396; 731, pp. 410-412).—A paper on this subject prepared with special reference to Spanish conditions and based upon various papers read before the International Congress of Agriculture.

Hot room callusing, F. T. BIOLETTI and L. BONNET (*California Sta. Circ.* 76, pp. 12, figs. 6).—In a previous bulletin of the station a method of callusing grape cuttings in beds of sand was described (E. S. R., 18, p. 549). The sand callusing bed, however, has been found to have many defects and inconveniences, most of which can be overcome by stratifying the cuttings in boxes of moss and callusing in a hot room. The hot room method, which has been adopted in California by all of the large producers of grafted vines, is here discussed in detail under the following headings: Methods of grafting, graft trays, callusing boxes, callusing materials, filling the boxes, the hot room, temperature, moisture, aeration, removal from the hot room, hardening, and planting.

Investigations on the practice of heading-in grapes, L. RAVAZ (*Ann. École Nat. Agr. Montpellier*, n. ser., 11 (1912), No. 4, pp. 285-323, figs. 7).—The author reviews the literature of the subject and gives an account of his investigations conducted for a number of years at the Montpellier Agricultural School.

Summarizing the results it appears that the practice of heading-in, if employed shortly after the flowering season, tends to increase production, but at the expense of quality.

Grape culture in Pennsylvania, W. H. SILL (*Penn. Dept. Agr. Bul.* 217, 1912, pp. 66, pls. 51).—A practical treatise, superseding Bulletin 128 of the same series (E. S. R., 16, p. 976), on commercial grape growing, discussing the extent and history of the grape industry, and the location, details of production, and business management of a vineyard.

Contribution to the study of olive varieties, J. RUBY (*Bul. Soc. Nat. Agr. France*, 72 (1912), No. 3, pp. 299-316).—A classification of the related varieties of olives growing in France, based upon the shape of the fruit. The important characteristics of each variety are indicated, together with its common name, cultural region, and composition of pulp.

Protecting the California orange crop from frost, A. G. MCADIE (*Mo. Weather Rev.*, 39 (1911), No. 12, pp. 1910-1912).—The author reviews the conditions prevailing in California during the frost period of December, 1911, compares the results with those of previous years, and cites examples in which citrus orchards were successfully protected from frost damage by the use of smudges and orchard heaters.

Keeping quality of citrus fruit treated to eliminate frosted fruit, C. W. MANN (*Cal. Cult.*, 38 (1912), No. 19, pp. 582, 599, 607).—A review of the results secured in a number of California packing houses in the use of distillate or kerosene oil and of alcohol in separating frosted citrus fruit from sound fruit.

The alcohol method has proved the most satisfactory, the fruit being uninjured by the treatment, except where the skin has been previously punctured or broken. The use of distillate in the treatment of oranges generally shows a bad effect on the flavor of the fruit and results in an increased percentage of rot.

Alcohol for separation of frosted fruit, D. C. LEFFERTS (*Cal. Cult.*, 38 (1912), No. 19, pp. 583, 584).—The author reports progress during the past

season in the use of an alcohol bath for the separation of frosted oranges from sound fruit (E. S. R., 22, p. 737). The results to date indicate that in certain cases the specific gravity of good fruit may be sufficiently variable as to cause difficulty in the use of the bath.

**Fruit drying**, W. J. ALLEN (*Dept. Agr. N. S. Wales, Farmers' Bul. 52, 1911, pp. 22, figs. 17*).—A popular treatise on methods of drying apricots, peaches, lectarines, prunes, figs, apples, pears, and raisin and currant grapes, including a description of the necessary equipment.

**Morphologic-physiologic investigations of the flowers of coffee species**, F. C. VON FABER (*Ann. Jard. Bot. Buitenzorg, 2, ser., 10 (1912), pt. 1, pp. 59-160, pls. 12*).—This is a contribution to the knowledge of the physiology of the coffee plant, based partly on material secured from the author's experimental garden and partly on material from the Buitenzorg Botanical Garden. The subject matter is presented under the following general headings: Development processes, morphology and cytology of the coffee flower; fructification; processes subsequent to fructification; abnormalities in development; experimental investigations on the pollination and fructification of coffee species; physiological investigations of pollen grains; a partial sterility of coffees; the occurrence of small constant sterile flowers in various coffee species; general considerations on sterility; the cause of sterility in coffee; and experimental tests on the influence of exterior factors on the formation of sexual organs in *Coffea liberica*, *C. arabica*, and Kalimas hybrid, a supposed hybrid of these species.

**Coffee culture**, O. TELLEZ (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr., 1 (1911), Nos. 4, pp. 287-308, pls. 2; 5, pp. 391-407, pls. 4; 6, pp. 502-519, pls. 4*).—A popular treatise on the establishment, culture, and management of a coffee plantation.

**Fertilizer experiments with coffee**, G. HELMICH (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr., 1 (1911), Nos. 1, pp. 7-26, pls. 2; 2, pp. 104-120, pls. 8*).—The results of several years experiments in the use of artificial fertilizers on some coffee plantations in Mexico are reported.

**The coco palm and its culture**, P. PREUSS (*Die Kokospalme und ihre Kultur. Berlin, [1911], pp. VII+221, pls. 17, figs. 21; rev. in Naturw. Rundschau, 27 (1912), No. 16, pp. 206, 207*).—This is a practical treatise on the botany, uses, culture, insect pests, and diseases of the coconut palm (*Cocos nucifera*), including also information relative to preparation and marketing of the products and statistics of production and commerce.

A bibliography is appended.

**Roses**, H. R. DARLINGTON (*London and Edinburgh, [1911], pp. XII+193, pls. 8*).—In addition to cultural details, selections and descriptions are given of various kinds of exhibition, garden, and climbing roses, together with a calendar of operations for each month of the year.

A bibliography on roses is appended.

**Planning and adorning the farmstead** (*Iowa Sta. Bul. 126, pp. 23-44, figs. 15*).—This bulletin comprises 2 articles which relate to the planning and development of the farmstead, both from the standpoint of convenience and of securing an attractive landscape effect.

*Planning and adorning the farmstead*, A. T. Erwin (pp. 23-37).—Suggestions are given for the location of buildings, drives, walks, trees, shrubbery, lawn making, etc. A selected list of trees, shrubs, vines, etc., is given.

*Planning the farm in relation to the farmstead*, J. B. Davidson (pp. 38-41).—The author here presents a number of principles which should be considered in planning the farm for convenience, together with plans showing a good arrangement and a poor arrangement of farm buildings.

## FORESTRY.

**A classification for forestry literature** (*Yale Forest School Bul. 1, 1912, pp. 6*).—This classification has been prepared by the faculty of the Yale Forest School to supply the demand for a simple and comprehensive classification adapted to any library system. The general divisions are as follows: General works, forest botany, silviculture, forest protection, lumbering, forest management, forest technology, history and statistics, forest influences, and forest policy.

**Annual progress report of forest administration in the Western and Eastern Circles of the United Provinces for the forest year, 1910-11**, B. B. OSMASTON and J. S. CAMPBELL (*Ann. Rpt. Forest Adm. West. and East. Circles [India], 1910-11, pp. 18+8+18+XCIX+2*).—This is the usual report relative to the constitution, management, and exploitation of the state forests in the Western and Eastern Circles of the United Provinces, including also a report of the district protected forests in the Kumaun division. The important data relative to alterations in areas, forest surveys, forest protection, silvicultural operations, yields, revenues, etc., are appended in tabular form.

**Annual administration report of the forest department of the Madras Presidency for the twelve months ending June 30, 1911**, P. M. LUSHINGTON, H. B. BRYANT, and J. S. BATTIE (*Ann. Adm. Rpt. Forest Dept. Madras, 1911, pp. 66+CX+16*).—This is the usual report relative to the constitution, management, exploitation, and administration of the state forests in the Northern, Central, and Southern Circles of the Madras Presidency, including financial statements for the year. The important data relative to areas, working operations, yields, revenues, etc., are appended in tabular form.

**The important timber trees of the United States**, S. B. ELLIOTT (*Boston and New York, 1912, pp. 382, pls. 32*).—This work, which is based in part on the author's personal observations and in part on the literature of the subject, is offered as a manual of practical forestry for the use of foresters, students and laymen in forestry, lumbermen, farmers and other landowners, and all who contemplate growing trees for economic purposes.

**Silviculture**, C. WERCKLE (*Bol. Fomento [Costa Rica], 1 (1911), No. 12, pp. 948-953, figs. 2*).—Descriptive notes are given of the important timber and rubber trees of Costa Rica.

**Forest catalogue of Mexico** (*Catalogo Forestal de la Republica Mexicana. Mexico: Govt., 1912, pp. 29*).—This comprises a catalogue of the more important trees and shrubs forming the woods in the tropical, temperate, and cold regions of Mexico. The data given include the habitat, common and scientific names, and industrial uses. Partial information is also given on a large number of unidentified trees.

**The hardy catalpa** (*Catalpa speciosa*) (*Kansas Sta. Circ. 20, pp. 19, pls. 8, fig. 1*).—A popular treatise on catalpa culture, discussing methods of identifying the hardy catalpa (*C. speciosa*), methods of propagation, planting stock, selection of site, planting operations, cultivation and care, protection against rabbits, cutting back, form and size, fungus disease, length of rotation for the catalpa, second crop, cutting, seasoning, durability and character of catalpa wood, range of successful growth, and catalpa growing as a commercial enterprise.

**On the histology of woods of *Biota orientalis* and *Thuja occidentalis***, F. HOLLENDONNER (*Bot. Közlem. [Budapest], 11 (1912), No. 2, pp. 45-57, figs. 7*).—A detailed study of the wood structure in the above named species.

**A note on some germination tests with sal** (*Shorea robusta*) seed, R. S. TROUP (*[Indian] Forest Bul. 8, 1912, pp. 13*).—The tests here reported in detail were made to ascertain to what extent the fertility of sal seed is affected by

the size and condition of the trees producing it and by the locality and the type and density of the forest in which the trees grow.

Of the factors observed the time of collection was the only one which appeared to have an influence on the fertility of the seed. The most fertile seed were obtained at the middle of the seeding period.

**Influence of the origin and germinative power of pine seed upon the progeny,** G. SCHRÖDER (*Deut. Landw. Presse*, 39 (1912), Nos. 36, pp. 421-423, fig. 1; 37, pp. 437, 438).—A popular summary of European investigations.

**Monograph on the rubber industry in Bolivia,** M. V. BALLIVIÁN and C. F. PINILLA (*Monografía de la Industria de la Goma Elástica en Bolivia. Bolivia: Govt., 1912, pp. V+354+LXXXIV+III, pls. 9*).—This monograph contains general considerations relative to the geography, climatology, and resources of Bolivia and discusses in detail the rubber industry of the country relative to its history, botany, methods of exploitation, and marketing. A statistical account is given of the industry in the various producing regions of Bolivia and the laws relating to the industry are appended.

**Growing a woodlot from seed,** J. A. FERGUSON (*Missouri Sta. Circ. 52, pp. 139-146, figs. 2*).—Popular instructions are given for starting a forest nursery and the establishment of a woodlot on the farm, including tabular data regarding the collecting, storing, and planting of tree seeds.

**Results of sand and ravine binding work in Russia** (*Ezheg. Lies. Dept., 1 (1909), pp. 423-494*).—An account is given of sand and ravine binding work conducted in the Voronezh, Kharkov, Poltava, Saratov, and Samara provinces of Russia. Little attention has been paid to the restoration of ravines thus far. The fixation of sand dunes has been done largely with sand willows and pines.

**Note on the antiseptic treatment of timber in India, with special reference to railway sleepers,** R. S. PEARSON (*Indian Forest Rec., 3 (1912), No. 2, pp. 107, pls. 9, fig. 1*).—This note briefly reviews past experiments made in India with special reference to the preservation of railway ties, reports the results of the experiments made at the Imperial Forest Research Institute during the past 2 years with a variety of antiseptic solutions, and gives a résumé of the work which it is proposed to carry out in the future.

**On wood preservation with fluorids,** R. NOWOTNY (*Österr. Chem. Ztg., 15 (1912), No. 8, pp. 100-102*).—The author describes some experiments recently started in Austria in the use of bellit, a new fluorid combination, for the preservation of wooden poles, and gives a progress report on the comparative tests of zinc fluorid, copper sulphate, and creosote for preserving poles (*E. S. R., 20, p. 544*). The tests were started in 1905 and 1906.

An inspection of the poles in 1911 indicated that creosote was by far the most efficient preservative and that zinc fluorid was much more efficient than copper sulphate. The cost of creosoted poles, however, was considerably higher than those treated with zinc fluorid.

The experiments are to be continued.

**How to prolong the life of fence posts,** J. A. FERGUSON (*Missouri Sta. Circ. 51, pp. 135-138, fig. 1*).—A popular circular discussing various methods of prolonging the life of fence posts, in which special consideration is given to the use of creosote by the open tank method (*E. S. R., 19, p. 150*). A simple form of open tank is described.

## DISEASES OF PLANTS.

**Diseases and injuries to cultivated plants in 1909** (*Ber. Landw. Reichsamte Innern, 1911, No. 25, pp. VIII+270*).—A summary is given of literature relating to plant diseases and insect pests and their control.

**Fungi, an attempt at their classification, P. VUILLEMIN** (*Les Champignons, Essai de Classification. Paris, 1912, pp. VII+425*).—This is one of a series of 12 volumes treating of fungi. It contains a historical review of different systems of classification, after which the author treats of the grouping of fungi according to their cytological and biological characters.

Some new parasitic fungi of Japan, M. SHIRAI and K. HARA (*Bot. Mag. [Tokyo], 25 (1911), No. 299, pp. 69-73, pl. 1; abs. in Bul. Trimest. Soc. Mycol. France, 27 (1911), No. 3, p. 397*).—The authors report, with illustrations and descriptions, the following new species of Japanese fungi: *Lophodermium chamæcyparisi*, *Asterula chamæcyparisi*, *Phaospharella japonica*, *Leptosphaeria cinamomi*, *Mycospharella paulownia*, *M. zingiberi*, *M. macleaya*, and *Sphaerulina aucuba*.

Notes on the Japanese species of *Phragmidium*, M. KASAI (*Trans. Sapporo Nat. Hist. Soc., 3 (1909-10), pp. 27-51, pl. 1*).—The author describes 17 species of *Phragmidium* occurring in Japan, 11 of which are peculiar to that country and 3 are new to science. The species occur parasitically on *Potentilla*, *Rubus*, *Rosa*, and *Sanguisorba*.

Cardinal temperatures for the germination of uredospores of cereal rusts, E. C. JOHNSON (*Abs. in Phytopathology, 2 (1912), No. 1, pp. 47, 48*).—The author has made a study of the effect of temperature on the germination of the spores of cereal rusts, believing that it would throw further light on the relation of meteorological conditions to rust development. The investigations were carried on with the uredospores of *Puccinia graminis* on wheat, barley, and oats, *P. rubigo-cera* on wheat and rye, and *P. coronata* on oats. The spores were obtained from fresh material, and the germinations were made in distilled water in incubators in which the temperature ranged from 1.5 to 31° C.

In the experiments the maximum and minimum temperatures for the different rusts were as follows: *P. graminis*, from 2 to 31°; *P. rubigo-cera* on wheat and rye, about the same; *P. coronata* on oats, a higher minimum, 7 to 8°, with a maximum of 39°.

The optimum temperature could not be definitely determined by percentages, on account of the lack of uniformity between 9 and 25°. From the development of the germination tube, the optimum temperature appeared to be between 12 and 17° for all the forms studied.

These low cardinal temperatures are believed to explain such points as the difficulty with which infection takes place in excessively warm greenhouses and on hot days; the difficulty of finding viable uredospores in early spring, the majority already having germinated; and the favoring of rust development and epidemics by subnormal temperatures at the critical infection periods of the host plants.

A new method of combating smut of cereals, G. D'IPPOLITO (*Bol. Quind. Soc. Agr. Ital., 16 (1911), No. 19, pp. 680-685; abs. in Riv. Patol. Veg., 5 (1911), No. 9, pp. 133*).—The main features of this method are (1) steeping the grain in water at from 20 to 22° C. for 4 hours to start the growth of the internal mycelium and (2) placing it in water at 52° for 10 minutes to kill the growing fungus.

Ergot on oats, C. W. WARBURTON (*Bot. Gaz., 51 (1911), No. 1, p. 64, fig. 1; abs. in Centbl. Bakt. [etc.], 2. Abt., 32 (1912), No. 6-12, pp. 300, 301*).—The author reports the discovery at Ames, Iowa, of ergot (*Claviceps purpurea*) on oats, a disease said to be new in the United States. The attack was noted on a variety immune to smut in July, 1909, a wet season favorable to ergot epidemics. It did not reappear in the dry season of 1910.

Leaf spot of oats, H. NILSSON-EHLE (*Sveriges Utsädesför. Tidskr., 21 (1911), No. 1, pp. 54-56, pl. 1; abs. in Bot. Centbl., 116 (1911), No. 23, pp. 603,*

604).—The author, in resumption of previous work on *Scolecotrichum* (E. S. R., 23, p. 46), mentions the fact that this disease, known in Sweden for about 20 years and associated with too strong a liming of the soil, is best controlled by the application of ammonium sulphate, a remedy already in successful use by cultivators in more southern lands.

**A Sclerotium disease of blue joint and other grasses, A. B. STOUT** (*Wisconsin Sta. Research Bul. 18, pp. 207-261, pls. 8*).—A study is reported of a disease of blue joint and other grasses, which was begun by the author in the summer of 1907.

The disease is due to the fungus *S. rhizodes*, which attacks the leaves of various grasses, causing them to become dried, rigid, and bent into characteristic shapes. Upon the leaves felts of mycelium are produced from which sclerotia are developed. The development of the fungus on the leaves is most vigorous during April and May, when the death of the entire culm may result.

The fungus has been found on 11 species of grasses about Madison, Wis., being especially destructive to *Calamagrostis canadensis*, which serves as its principal host. It is vigorously parasitic on the leaves, less so in the buds and stems, and but slightly so on the roots, where it assumes some of the characteristics usually associated with mycorrhiza.

The fungus is said to be of considerable economic importance, having destroyed or dwarfed as much as 45 per cent of the plants of *C. canadensis* in a meadow near Madison, Wis., in the season of 1911. It seems to be quite generally distributed throughout Wisconsin, but has not been reported elsewhere in America.

Further data are desired on additional host plants, geographic range of the fungus, economic importance, germination of the sclerotia, and infection of the seedlings.

A bibliography of the subject is included.

**Potato crop and seed, O. APPEL** (*Illus. Landw. Ztg., 31 (1911), No. 15, pp. 134-136; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, pp. 396, 397*).—In continuance of previous work (E. S. R., 21, p. 243; 22, p. 347; 23, p. 148) the author discusses the various potato diseases of Germany in connection with the problem of their prevention as related to seed tubers and their treatment. The recommendations made include (1) sufficient drying on harvesting to check multiplication of bacteria and permit formation of wound cork, and (2) the selection of good sized tubers from healthy and well bearing plants.

**Blackleg of potato, W. BEHRENS and G. MARPMANN** (*Ztschr. Angew. Mikros., 16 (1911), No. 4, pp. 94-99; abs. in Centbl. Bakt. [etc.], 2. Abt., 32 (1912), No. 6-12, pp. 326, 327; Bot. Centbl., 119 (1912), No. 8, p. 192*).—The authors report that an examination of plants injured by insects and affected by this disease showed no bacteria directly, but it is claimed that culture methods gave 7 characteristic species of which 2 appeared able to produce the disease. These are described. It is suggested that inoculation on a larger scale, and under more nearly natural conditions than those employed, might lead to more positive results.

**Inheritance of leaf-roll disease, A. SCHMID** (*Illus. Landw. Ztg., 31 (1911), No. 17, p. 160; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, pp. 331, 332*).—The recent invasion of parts of Switzerland by this disease and resulting decrease of crops led to an experimental study of the possible hereditary effects of its attacks. Nineteen sound and 19 diseased tubers of like sort and size from the same field were planted and the resulting vegetation and crops compared. It was found that the plants from the diseased tubers were backward and showed the characteristic leaf-roll form, while the crop was

only about 21 per cent of that from the sound tubers. The weather was abnormally damp during the experiment.

The factors governing germination and infection with *Phytophthora infestans*, I. E. MELHUS (*Abs. in Phytopathology*, 2 (1912), No. 1, p. 46).—In experiments involving about 300 tests at temperatures ranging from 8 to 14° C., 96 per cent of the spores germinated, while at 21 to 25° only 20 per cent germinated, indicating that comparatively low temperatures favor germination with *P. infestans* as well as with *Cystopus* (E. S. R., 26, p. 342). The optimum temperature for oospore germination was found to lie between 10 and 13°, the minimum between 1 and 2°, and the maximum between 21 and 24°. Field observations showed oospore germination to occur freely on potato plants at temperatures between 8 and 15°.

Inoculation experiments showed that temperatures of 10 to 13° produced higher percentages of infection than 21 to 25°, and that the upper surface of the potato leaf is less easily infected than the lower.

The effect of Bordeaux mixture and various polysulphids on the germination of *P. infestans* and *Plasmopara viticola* was investigated. Varying the amount of lime in Bordeaux mixture did not affect the toxicity. None of the constituents of the polysulphids was found toxic at the proportion occurring in the polysulphid. The most nearly toxic agent, however, was the alkaline constituent.

**Hypertrophy-structure in potatoes.** M. FÜCSKÓ (*Bot. Közlem. [Budapest]*, 11 (1912), No. 1, pp. 17-29 (3)-(11), figs. 10).—This is a study of the structure of the abnormal developments resulting from an oversupply of water in contact with tubers. These are figured and described. One result is the formation of abundant starch in the sublenticular cells. This, however, seems to be transitory. A regular periodicity is said to be apparent in the formation of these excrescences.

**Relative merits of lime sulphur, lead benzoate, and Bordeaux mixture for spraying potatoes.** F. C. STEWART and G. T. FRENCH (*Abs. in Phytopathology*, 2 (1912), No. 1, pp. 45, 46).—In 1911 the authors made a comparative test of lime-sulphur, lead benzoate, and Bordeaux mixture for spraying potatoes, the mixtures being thoroughly applied 6 times at intervals of 2 weeks. Tip burn was the only important disease involved. Bordeaux mixture checked this, prolonged the life of the plants, and increased the yield at the rate of 100.3 bu. per acre; lead benzoate was found to neither benefit nor injure the plants; while those sprayed with lime-sulphur were smaller than the checks, as much affected by tip burn, and yielded 39.5 bu. less per acre than the checks.

The conclusion reached is that neither lime-sulphur nor lead benzoate can be profitably substituted for Bordeaux mixture in spraying potatoes. Both lack the stimulating influence possessed by Bordeaux mixture, while lime-sulphur tends to dwarf the plants and lower the yield.

**Nematode disease of the sugar beet.** B. NÉMEC (*Ztschr. Pflanzenkrankh.*, 21 (1911), No. 1-2, pp. 1-10, figs. 6; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, pp. 311, 312; *Bot. Centbl.*, 116 (1911), No. 24, pp. 623, 624).—This is a study of the anatomical changes observed in roots of the sugar beet as the result of attacks by eelworms.

Most noticeable are the so-called giant cells which develop by growth and fusion of cells in the vascular bundles, sometimes closing the channels completely. Such giant cells have thick walls and abundant cytoplasm, sometimes with several large nuclei. They are said to hinder or interrupt transportation of water and other materials along the roots attacked, and by checking root-tip growth they lead to the development of new lateral roots and the impoverish-

ment and exhaustion of the plant. This becomes yellowed, and easily wilts and dies in case of unusual heat or dryness. The losses observed in crop returns are said to be due to the impoverishment of the plant, (1) by stoppage of channels and (2) by withdrawal of material (a) for the building of the giant cells and of the lateral roots and (b) for the nourishment of the parasites. The parasites are thought to produce on entering the root a stimulation which occasions the observed abnormal cell development. The giant cells are thought to function somewhat as glands or nectaries, producing material suitable for nourishment of the nematodes.

**Averting nematode injury**, KRÜGER (*Bl. Zuckerrübenbau*, 18 (1911), Nos. 17, pp. 294-300; 18, pp. 311-313; *abs. in Ztschr. Landw. Versuchsw. Österr.*, 14 (1911), No. 12, p. 1479).—This is a preliminary report on the author's study of nematodes on sugar beets continued for 4 years and not yet completed, but from which the following conclusion may, in his opinion, be justly drawn:

Nematode attack is favored by poverty of soil, by injurious constituents therein, and by attacks of other parasites. Two plans for the protection of the crop are indicated. The first, which aims to limit increase and perpetuation of the infection, consists in removing all such weeds and offal from the beets as might help to shelter and nourish the parasites. The second plan, which aims at destruction of the parasites, consists in the employment of lime, carbon bisulphid, etc., and of the Kühn method of trap-plants. It is believed that by these means the injury may be greatly reduced, if not entirely prevented.

**A new method for combating the sereh disease of sugar cane**, T. VALETON, Jr. (*Teysmannia*, 22 (1911), No. 12, pp. 767-772).—Attention is called to the occasional resistance of certain varieties of cane to this disease, and the probable value of breeding experiments to fix and extend these forms is discussed.

**A new fruit disease of eggplant**, J. HANZAWA (*Trans. Sapporo Nat. Hist. Soc.*, 3 (1909-10), pp. 83-87, pl. 1).—A description is given of *Rhabdospora melongenæ* n. sp., a fungus that sometimes causes a severe rotting of the fruit of the eggplant.

**Withertip of fruit and ornamental trees**, E. VOGES (*Deut. Landw. Presse*, 39 (1912), No. 24, pp. 285, 286, figs. 4).—An account is given of a disease of twig ends of cherry, poplar, and other trees, resulting in their speedy death, while neighboring twigs continue to appear healthy. Investigation revealed the presence of certain fungi in the affected parts. Of these, 3, described and illustrated, are said to be *Nectria ditissima*, *Fusarium willkommii*, and *Monilia cinerea*.

**Cement dust injury to fruit trees**, P. J. ANDERSON (*Abs. in Phytopathology*, 2 (1912), No. 1, p. 45).—An investigation has been begun at the request of certain fruit growers to determine the effect of dust from cement mills.

The dust was found to contain a high percentage of soluble calcium salt. This dissolved in the stigmatic secretions and rendered them alkaline, and pollen would not germinate in the alkaline solution. Artificial tests of the pollen of cherries, pears, and apples gave no germination, even in very weak solutions of the dust. Further tests showed that there was no germination even when the calcium was not in an alkaline condition.

**Foliage diseases of the apple**, H. S. REED, J. S. COOLEY, and J. T. ROGERS (*Virginia Sta. Bul.* 195, pp. 23, figs. 13).—This bulletin is based on experiments made during the years 1910 and 1911, the diseases investigated being the frog-eye leaf spot, cedar rust, and apple scab as a foliage disease.

The frog-eye leaf spot is said to be widely distributed and is probably due to a number of fungi which produce similar appearances on the leaves. The varie-

ties Ben Davis and Black Twig seem more subject to this trouble than others, York Imperial suffering less severely and Winesap being hardly affected at all.

During the seasons of 1910 and 1911 spraying experiments for the control of these leaf diseases were carried on in a number of places in Virginia to test the value of different fungicides, the times of application, etc. The experiments showed that dilute lime-sulphur solution is as effective in controlling the leaf spot and scab as standard Bordeaux mixture. Where the scab is not abundant the first spraying should be made immediately after the falling of the flowers, followed by a second and third application at intervals of from 15 to 20 days. Where scab is abundant an additional application of the spraying material should be made just before the blossoms open. Bordeaux mixture appeared to be the only fungicide which was successfully used for combating bitter rot. For this purpose 3 applications should be given the trees, the first between June 20 and July 1, with subsequent sprayings at intervals of from 15 to 20 days. The addition of iron sulphate to lime-sulphur or Bordeaux mixture was found to increase the sticking properties of the fungicides without affecting their value in any sense. It was also found that arsenate of lead aside from being a good insecticide had some value as a fungicide.

The injury to the foliage attributed to spraying mixtures is sometimes caused by the use of too great quantity or improperly made mixtures. It was found that fruit may be burned with lime-sulphur if sprayed in very hot weather. Tender skinned apples were affected by Bordeaux mixture in a similar way if sprayed early in the season. The danger of russetting is very slight 2 months after blooming and later. Where early applications of the fungicides are necessary the authors recommend the use of lime-sulphur for the first 2 sprayings.

**Experiments on the simultaneous treatment for the control of downy and powdery mildew, G. MARTELLI** (*Separate from Agr. Etneo, 1911, No. 4, pp. 7*).—The results of experiments for the combined treatment of grapes to control the downy and powdery mildew are given. The vines were sprayed with Bordeaux mixture to which was added an alkaline polysulphid. Bordeaux mixture followed by applications of sulphur, and a proprietary mixture of copper and sulphur. Three applications were given to different lots of over 6,000 grapevines in the experiment, and the cheapest and most efficient fungicide was the Bordeaux mixture combined with the alkaline polysulphid.

**Invasion of Europe by the American gooseberry mildew and oak mildew, G. KÖCK** (*Ztschr. Pflanzenkrankh., 20 (1910), No. 8, pp. 452-455; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, p. 345*).—This continues communications by the author on this subject (*E. S. R., 22, p. 743; 23, p. 50; 24, p. 747*), giving here dates and places of first appearance or early appearances of each of these mildews in this region.

**The influence of Hemileia vastatrix on the culture of coffee in Java, P. S. J. CRAMER** (*Rev. Agr. Nouvelle-Calédonie, 1911, Nos. 12, pp. 24-50; 13, pp. 16-24*).—An account is given of *H. vastatrix* in Java, the influence it has had on the Arabian coffee production, and means that have been undertaken for its control.

The production of coffee under government control in Java has fallen from an average of 923,333 piculs (123,111,100 lbs.) in the 5 years from 1880 to 1885 to 81,746 piculs in the 2 years from 1906 to 1908, due, it is claimed, to the disastrous invasion of the fungus. To combat the disease, spraying and the growing of resistant varieties have been resorted to. *Coffea liberica*, *C. robusta*, and other species, and some of their hybrids appear quite resistant, and their introduction has been successfully accomplished. Spraying with Bordeaux mixture

has been followed with good results in seed beds and nurseries, but its use in the plantation is thought to be impracticable.

The author comments on the absence of this fungus in American coffee raising countries, and attributes it to a number of factors, among them a lack of suitable climatic conditions, natural enemies of *Hemileia* in America, and the absence of suitable host species on which the alternate generations of the fungus may develop.

**Injury to pines by smelter gases**, K. FEIST (*Arch. Pharm.*, 249 (1911), No. 1, pp. 7-9; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, p. 331; *Bot. Centbl.*, 116 (1911), No. 21, p. 553).—This is an account of the author's investigation of the changes produced in the foliage of pines injured by exposure to gases evolved in the smelting of siderite. Comparative examination of the needles of sick and of sound pines showed that the percentage of ash was considerably increased in case of the former. There was also a notable increase of sulphuric acid, which could come only from the air, while the alkalinity of the ash itself was considerably lowered.

**New fungi on Japanese bamboos**, J. MIYAKE and K. HARA (*Bot. Mag. [Tokyo]*, 24 (1910), No. 286, pp. 331-341; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 31 (1911), No. 11-15, pp. 321, 322).—The authors give the results of their studies on a number of fungi of which the following appear to be new: *Lasiosphæria culmorum*, *Guignardia bambusa*, *Mycosphærella bambusifolia*, and *Phæosphæria bambusa*. The article is mainly in the Japanese language.

**The importance of sanitation in the control of certain plant diseases**, L. R. JONES (*Abs. in Phytopathology*, 2 (1912), No. 1, p. 46).—The author states that while fungicidal sprays must continue to be the chief reliance in combating many plant diseases, more attention should be given to the fundamental sanitary measures to secure the healthy development of the host plants. Recent experiments in Wisconsin have shown this to be essentially true with certain diseases of crops introduced into new regions for trucking and canning. These include the cabbage diseases, especially club root, blackleg, and yellows, some pea diseases, the bacterial wilt of cucurbits, and crown gall of nursery plants.

**The covering power of the precipitation membranes of Bordeaux mixture**, B. F. LUTMAN (*Phytopathology*, 2 (1912), No. 1, pp. 32-41, figs. 6).—A study on the physical properties of the precipitate of Bordeaux mixture is reported, in which an attempt was made to measure as nearly as possible the actual area of the precipitation membrane produced by copper sulphate solution and lime water, or milk of lime. Six formulas were used, including that known as Pickering's Bordeaux mixture.

About 100 cc. of the Bordeaux mixtures was made up, 1 cc. diluted with from 200 to 400 cc. of water, and  $\frac{1}{2}$  cc. of this dilution placed on a cover glass and allowed to dry, after which the membranes were examined microscopically, drawn, and their relative area measured. It was found that increasing the amount of copper sulphate and lime increases the area of precipitation film produced.

The amount of precipitation membrane, as shown by precipitation in hydrometer jars, was determined. The Pickering's Bordeaux showed an apparently large amount of precipitate. This was only apparent, however, as shown by the actual measurements which were given.

In conclusion the author calls attention to the fact that bulk for bulk the same quantity of Pickering's Bordeaux mixture does not have the same covering power as even the  $2\frac{1}{2} : 2\frac{1}{2} : 50$  mixture. On the other hand, for the amount of material used it produces the greatest amount of film area.

## ENTOMOLOGY.

**Report of the entomologist, D. T. FULLAWAY** (*Hawaii Sta. Rpt. 1911, pp. 17-24, figs. 4*).—This report consists principally of notes on insects attacking leguminous crops, including the pigeon pea (*Cajanus indicus*), cowpea (*Vigna catjang*), jack bean (*Canavalia ensiformis*), velvet beans (*Mucuna pruriens*), soy bean (*Glycine hispida*), peanut (*Arachis hypogaea*), sweet clover (*Melilotus officinalis*), and alfalfa (*Medicago sativa*), especial attention having been given to the enemies of the pigeon pea.

The army worm (*Heliophila unipuncta*) sometimes devastates large fields of alfalfa before it can be brought under control by its natural enemies, and extensive plantings of jack beans have been made waste by *Spodoptera mauritia*, another common army worm. The foliage of legumes is often badly eaten by certain leaf-rollers, *Omiodes monogona*, *Amorbia emigratella*, and *Archips postvittanus*, and by the looper, *Plusia chalcites*, but the damage they inflict is apparently not great except in the case of *O. monogona*, which, so far as is known, feeds exclusively on legumes. It, however, is subject in turn to the attacks of parasites which keep it fairly well in check. *Limnerium blackburni* and *Chalcis obscurata* have been bred from *O. monogona*. The plant louse which attacks legumes is thought to be *Aphis gossypii*. "The larvæ of the syrphid fly, *Xanthogramma grandicornis*, and of the agromyzid, *Leucopis nigricornis*, also prey on aphids and are usually found where aphids are abundant. . . . The cottony cushion or fluted scale, *Cercya purchasi*, which, while normally controlled by *Norius cardinalis*, sometimes becomes very abundant and does considerable damage before the ladybirds become numerous enough to clean it out. . . . Mealy bugs, embracing several species, infest legumes, notably *Pseudococcus longispinus*, *P. citri*, *P. virgatus*, and *P. famentosus*, but do little apparent damage and are usually controlled by their parasites and predators. The first 3 species have been noticed on pigeon pea and the last more especially on clover. The flat scale, *Saissetia olea*, is common on pigeon pea and crotalaria. The leaves of most of the cultivated legumes, and some other plants as well, are mined by the larvæ of *Agromyza diminuta*." It is thought that this miner will never be a serious pest since it is effectively parasitized by the eulophids *Omphale metallicus* and *Pediobius* sp. The bean pod borer, a caterpillar of the common butterfly *Lycana batuca*, is thought to be the most injurious insect attacking legumes, and notes on its life history are presented.

"The dry pods and seeds of legumes are attacked in storehouses and somewhat in the field by certain insects which habitually feed on stored products, notably bruchid weevils. . . . *Bruchus chinensis* and *B. prosopis* have been bred from seeds of the pigeon pea, *B. chinensis* from seeds of the cowpea, and *B. prosopis* and *Caryoborus gonagra* from seeds of keawe (*Prosopis juliflora*). The ptinid beetle *Catorama mexicana* has been bred from seed of the velvet bean, and the common coffee bean-weevil (*Aræcerus fasciculatus*) from pigeon pea seed stored and in the field."

The minor pests observed include *Trichothrips nigricans*, which is abundant in the blossoms of the pigeon pea; *Xiphidium varipenne*, which sometimes feeds on legumes, but is largely carnivorous in habit; a red spider (*Tetranychus* sp.), noticed on the foliage; and bostrychids, which bore the broken stems. Observations of the capsid bug *Hyalopeplus peltucidus* failed to show any predatory inclination as previously reported to be the case.

Brief notes are also given on the occurrence and habits of the Mediterranean fruit fly.

A preliminary study of Kentucky localities in which pellagra is prevalent, H. GARMAN (*Kentucky Sta. Bul.* 159, pp. 3-79, pls. 27, figs. 24).—Within the past 2 years pellagra has attracted attention in some of the mountain counties of Kentucky from which a number of people have been sent to the state asylum at Lexington. At the request of a conference of medical men of the State the author visited the region where pellagra is prevalent with a view to determining whether any fly occurs there that might convey the disease. Several days were spent at Corbin in the latter part of August and in September, and at Pineville in October, in studying the localities in which pellagrous cases are located and giving special attention to the streams in the region as breeding places of the flies. The results of the investigation are here presented and discussed at length under the following headings: The streams, the insects, etc., found in the streams, including Simuliidæ, Chironomidæ, Culicidæ, Tipulidæ, Tabanidæ, Hemiptera, Coleoptera, Trichoptera, Neuroptera, Ephemera, Odonata, Plectoptera, Arachnida, Protozoa, Crustacea, Bryozoa or Polyzoa, Vermes, Mollusca, fishes and amphibians, also vegetation in and about the streams, and bacteria.

The work concludes with a discussion of the corn crops along the streams, the effect of moldy corn on stock, and the presentation of Dr. Sambon's theory of the transmission of pellagra by simuliids.

The sand flies discussed are *Simulium venustum*, *S. pccuarum*, *S. pictipes*, *S. meridionale*, and *S. reptans*. The author states that he has not at any time committed himself to the insect theory of the spread of pellagra, is not satisfied with the evidence, and in this bulletin has simply presented facts which may bear upon the problem.

The pear thrips, P. J. PARROTT (*New York State Sta. Bul.* 343, pp. 3-28, pls. 5, figs. 5).—This is a report of investigations of *Euthrips pyri*, which, as reported in the account previously noted (*E. S. R.*, 25, p. 658), has become the source of considerable injury to fruit at points in the Hudson River Valley, as well as in California (*E. S. R.*, 24, p. 455).

The author concludes from investigations conducted that the pest has been a source of injury in the Hudson River Valley for a period of some 5 years. "The most severe attack of the thrips occurred during 1910, when the pear crop in many orchards was much reduced. Besides losses in yields the trees were seriously checked by injuries to leaf buds and leaf clusters; and in some orchards the season was much advanced before the trees presented normal conditions of growth. The productiveness of pear orchards during 1911 was greater than the preceding year, but blighting of blossom clusters was general and orchards suffered losses in yields according to the severity of the attacks by the thrips."

"The adult insect attacks the developing buds, which checks the natural growth, and blossom clusters most seriously affected eventually fall. The deposition of eggs in the fruit stems weakens the stems, causing the young fruit to drop. The quality of prunes that mature may also be impaired by the feeding of the larvæ on the skin of the fruit causing a diseased condition known as 'scab.' The Napoleon Bigarreau and Black Tartarian cherries and Imperial prune are among the varieties known to New York fruit growers that are attacked by the thrips. Almonds, apricots, and peaches, while also subject to injuries, do not usually sustain such serious losses unless the thrips are very numerous." During 1911 it was observed in New York chiefly on apples, apricots, cherries, peaches, pears, plums, and quinces. "Apples were generally infested with thrips, but the destruction of blossom clusters was not so common as with the pears. In spite of the presence of large numbers of the thrips in the buds there was usually a large setting of apples. While all of the leading commercial varieties

were more or less infested by the thrips, the most conspicuous injuries to blossom and leaf clusters during the past season were observed with such varieties as Astrachan, Gravenstein, McIntosh, Ben Davis, and Oldenburg."

The life history of the pest is described, together with technical descriptions of its stages. "The date when the mature insects first appeared on the trees this spring was not obtained, but a few specimens were observed on April 26. They seemed to be most numerous and destructive from April 28 through the first week in May. With the falling of the petals from May 11 to May 14 the adults became less numerous on pear trees, and practically disappeared from plantings of this fruit by the latter part of the month. Oviposition was most active during the last few days of April and up to the middle of May. The first young thrips was detected on May 9, and on succeeding days larvæ emerged in large numbers, being very conspicuous in the calyx basins of the fruit following blossoming. The latest date of emergence of larvæ was May 25. The young thrips commenced to drop to the ground beneath the trees on May 17, when several of them were caught on sheets of sticky fly paper."

The actual range of distribution in New York has not been ascertained. While its destructiveness to pear orchards has attracted the attention generally of pear growers about North Germantown, Germantown, and Cheviot, scattering numbers of the insect have been observed on pears grown south of this region, about Tivoli, to the north about Stuyvesant, and eastward to a line running between Chatham, Glencoe Mills, and Clermont. On April 26 specimens of thrips were found at Geneva in apple buds, which plainly showed evidences of injury.

The author's experiments show that "the period for effective spraying is during the time when the buds are breaking and until they are entirely opened at the tips. The most promising spraying mixtures are the nicotin preparations in combination with kerosene emulsion or soap. Two or 3 applications on successive days during the past year largely prevented important injuries to pear trees. The physical features of the locations of the orchards, such as the direction and elevation of the slopes of the land, proximity to the Hudson River and character of the soil, have a marked influence on the development of the buds and the time of blossoming. The time for effective spraying will therefore vary with individual orchards."

**A new fruit tree enemy in New York, F. H. HALL** (*New York State Sta. Bul. 343, popular ed., pp. 8, fig. 1*).—A popular edition of the above.

**The grape leaf-hopper and its control, F. Z. HARTZELL** (*New York State Sta. Bul. 344, pp. 29-43, pls. 4, figs. 3*).—This paper treats of *Typhlocyba comex*, its life history and habits, food plants, and injury, with a brief report of experimental control work, conducted in continuation of that previously noted (E. S. R., 24, p. 751).

This important enemy of the grape is said to have been on the increase in Chautauqua County during the past few years. It "weakens the vines by piercing the epidermis of the underside of the leaf and sucking the cell sap, thus injuring the cells and exposing them to the drying action of the air. This injury results in a decrease in the amount of wood, and it also affects the quantity and quality of the fruit. Fruit from badly infested vines is poorly ripened."

"Experiments have proven that a spray containing 0.02 per cent nicotin is the most effective and safest contact insecticide for the control of the grape leaf-hopper. This must be directed against the nymphs, which are hit by applying the spray to the undersides of the leaves.

"The application of the spray for this insect can be done by the usual hand spraying with trailing hose or by an automatic leaf-hopper sprayer which is described in this bulletin. This latter device was developed during the past

season and it has done efficient work. With high pressure and proper adjustment of the nozzles the insect can be efficiently controlled."

**Fighting leaf-hoppers in the vineyard**, F. H. HALL (*New York State Sta. Bul.* 344, popular ed., pp. 8, figs. 3).—A popular edition of the above.

**Burn the chinch bug in winter quarters**, T. J. HEADLEE (*Kansas Sta. Circ.* 19, pp. 8, figs. 7).—This circular calls attention to the fact that it is imperatively necessary for the farmer to determine in the fall whether his grasses are harboring a dangerous number of chinch bugs, and to the importance of burning infested grasses late in the fall or early winter, as most of the bugs not killed by the fire perish from exposure.

Records made of the average winter mortality in different types of cover are as follows: Bunch grass 65 per cent; big bluestem 65 per cent; dry pieces of manure 98 per cent; Osage oranges 99 per cent; rubbish, leaves, etc., 99 per cent; turnips 99 per cent; corn husks and stalks 100 per cent; and Osage orange tree bark 100 per cent.

The great value of winter burning was demonstrated in the fall of 1910 in an area of 25 square miles in northern Sumner County. "During the months of November and December, 1910, a rectangular block,  $3\frac{1}{2}$  miles wide by 5 miles long, was stripped of its chinch-bug cover by fire and the remaining  $7\frac{1}{2}$  square miles were more or less completely burned. Although the burning was not as close as was desired, the average length of the stubble being 1.5 in., whereas it should have been less than 1 in., an average of 738 bugs out of every thousand present when the firing began were destroyed, and this mortality was raised to 984 per thousand by the first of the following March."

"From the time the bugs appeared in the wheat in the spring, as an average, they were from 6 to 20 times more numerous in the unburned district than in the burned sections. . . . The yield of the burned area averaged about 2.1 bu. more per acre than that of the unburned, showing that a saving of about \$7,000 was effected in wheat alone. Oats, being only slightly infested, showed little difference in yield. In the burned area the reduction of bugs was so great that no corn was killed at harvest time, while in the unburned area from 1 to 40 rows standing adjacent to wheat were sucked dry and completely ruined."

A map is given of the burned area and surrounding territory.

**The San José scale in Missouri**, L. HASEMAN (*Missouri Sta. Bul.* 98, pp. 61-116, figs. 16).—This is a general account of the San José scale, its history and introduction into Missouri, provisions for its control in Missouri, present distribution in the State, life history and appearance, development, reproduction, period of larval activity, methods of spread, food plants, injury, natural enemies, and remedial measures, with a brief report of control experiments.

The scale was first introduced into Missouri between 1891 and 1894. At the present time infestations have been located in one-third of the counties of the State, though the bulk of the scale is confined to some 6 counties. "The nurseries of the State so far as examined had remained apparently free of the scale until 1906, but since then slight infestations have been found in 3 or 4 small local nurseries and in 3 of the larger ones, but in each case it has been stamped out. . . .

"The lime-sulphur wash is by far the cheapest on the market, and when properly prepared and applied is just as effective for the control of the scale as any of the other washes, besides being an excellent remedy for plant lice and having fungicidal properties. . . . Of the 4 miscible oils tested it is impossible to detect any difference in their effect upon the scale. A fall and spring application of either of them at a strength of 1:15 is thoroughly effective. They should not be used at a greater strength except when only one application can be given, when 1 gal. of oil to 10 or 12 gal. of water will prove effective.

They should never be used at a greater dilution than 1:15. Summer spraying for the control of the scale with any of the washes so far tested is impracticable.

**Papers on insects affecting vegetables.**—The imported cabbage webworm (*Hellula undalis*), F. H. CHITTENDEN and H. O. MARSH (*U. S. Dept. Agr., Bur. Ent. Bul. 109, pt. 3, pp. 23-45, figs. 4*).—Since 1897 this webworm has repeatedly come under observation as a pest in additional States and Territories, namely, in Florida, Mississippi, North Carolina, Texas, California, and Hawaii, the reports of which are here presented. Technical descriptions of its stages are given in connection with life history notes.

A total of 296 eggs is recorded as deposited by a single female. At a temperature of from 80 to 84° F. the eggs hatched 3 days after deposition. "Besides cabbage, turnips and beets, collards, cauliflower, kale, rutabaga, radish, kohlrabi, mustard, rape, horse-radish and some other cultivated plants, such as 'Japanese radish,' are subject to attack and injury. Among weeds and wild food plants are the common shepherd's purse (*Bursa* [*Capsella*] *bursa-pastoris*), and 'pussley' or 'cutter's grass,' otherwise purslane (*Portulaca oleracea*)." The natural enemies mentioned include 2 tachinids (*Errorista pyste* and *Plagi-prospherysa* sp.), an ichneumonid (*Limnecrium tibiator*), and 2 other hymenopterous parasites, namely, *Meteorus vulgaris* and *Temelucha* (*Porizon*) *macer*.

Notes on the occurrence of the pest in Hawaii, together with a report of remedial experiments conducted by the junior author, follow, together with a list of the other enemies of cabbage in Hawaii.

"At Honolulu eggs have been observed to hatch in from 2 to 3 days. . . . The larvæ usually reach maturity in from 13 to 15 days. They then leave the plants, burrow slightly beneath the surface of the soil, and form rather frail cocoons of webbed-together grains of earth, within which they pupate within 2 days. . . . The adults usually issued in from 6 to 12 days after pupation. . . . Four generations of this webworm were reared in an insectary at Honolulu." One female lived in a cage for 10 days and deposited 235 eggs, while another lived 14 days and deposited 237 eggs.

It is concluded from the experiments reported that arsenicals can not be depended upon to control this species on cabbage. "In light of our present knowledge, the best methods of controlling this webworm consist of clean culture, the screening of seed beds, and thorough cultivation. The necessity of prompt destruction of crop remnants and the employment of other clean cultural methods can not be too strongly emphasized. . . . By screening the seed beds it is possible to prevent infestation until the time of transplanting. When this method is followed it is advisable to leave a few plants exposed near the screened beds [as traps]. . . . Inasmuch as the larva of this species pupate in frail cocoons near the surface of the soil, it is possible that thorough cultivation would crush some of the pupæ and at the same time induce a more vigorous growth of the plants."

A bibliography of 22 titles is appended.

**Papers on insects affecting vegetables.**—A little-known cutworm (*Porosagrotis vetusta*), F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Bul. 109, pt. 4, pp. 47-51, fig. 1*).—Reports received of the attack of this pest at Southern Pines and Poplar Branch, N. C., and Norfolk, Shelton, and Churchland, Va., in which vegetables, berries, and field crops were injured, are first considered. Brief descriptions are then given of the moth and larva; the eggs and earlier stages of the larva have not been observed. *Apanteles* n. sp., near *agrotidis*, and the tachinid fly *Linnæomyia picta* are said to be the only enemies of this insect that are known at the present time.

At Norfolk, Va., the use of arsenate of lead, 4 lbs. to 50 gal. of water, gave good results in combating the pest on parsley.

The fruit tree leaf-roller (*Archips argyrospila*), G. W. HERRICK (*New York Cornell Sta. Bul. 311, pp. 279-292, pls. 4, figs. 3*).—As noted in a previous account (E. S. R., 26, p. 758), this leaf-roller suddenly came into prominence in the spring of 1911 as a serious pest to apples and a minor one to pears in New York orchards.

The species was first described as of economic importance in 1869 when Packard reported it as attacking the cherry tree, but eastern growers have been comparatively free from its ravages. It has been bred by the author from larvæ on the apple, pear, sweet cherry, wild cherry, black walnut, and mountain ash. At Bethany Center the larvæ were found in abundance on plum, pear, quince, apple, and cherry trees.

“The larvæ appear as the buds are bursting, and begin to attack the unfolding leaves. They bend the leaves over and tie them together with silk. Within this sort of nest the larvæ live and eat the leaves. As soon as the blooms appear the larvæ begin to eat off the blossom stems and tie them together with silken threads, along with the leaves surrounding the blossom cluster. This webbing and tying together of the blossom clusters is a most pernicious habit because it interferes seriously with spraying for the codling moth. In one Baldwin orchard in which the larvæ were very abundant, the blossom clusters were so webbed together and covered over with silk, dried petals, and leaves that it was almost impossible to get the spray mixture into the calyx cup. As soon as the young apples or pears begin to set they are tied together with silk, while the larvæ live inside and gnaw cavities into the sides of the young fruit. . . . In New York orchards during the past season a very large number of pears and apples were totally destroyed by the larvæ, and many others were seriously marred and deformed. . . . The larvæ also work on the leaves, rolling them and living within the roll. Here, effectually hidden, they feed on the tender tissues of the leaves.”

The pest undoubtedly passes the winter in New York State only in the egg stage, one generation a year apparently being the normal habit. The eggs are laid in June in small oval convex patches on the bark of the smaller twigs, the major number being deposited during the middle days of the month. The eggs remain on the trees until the following May, or a period of more than 10 months. In 1911, eggs hatched as early as May 4 and were found hatching in the field in abundance on May 9.

“When the larva becomes full-grown it spins a very thin, flimsy web in a rolled leaf, or between the leaves that are tied together, and changes to a pupa. . . . In the cages in the insectary the pupal stage lasted 9 to 12 days. . . . Our records during the season of 1911 show that the moths were emerging nearly every day from June 5 to June 21, with the latest moth appearing June 24. . . . It is evident that by the middle of June the moths were emerging in greatest numbers and that they were almost entirely out before July.”

Four species of hymenopterous parasites were reared from larvæ and pupæ in cages. Many primary and secondary parasites and at least 1 tertiary parasite were reared in the field. *Pimpla conquisitor* was the parasite reared in greatest numbers, the others being *Amicroplis* sp., *Phytodictus vulgaris*, *Sympiesus* sp., *Pimpla inquisitor*, *Glypta simplicipes*, and *Careelia nigropalpus*.

Methods of control have been summarized by the author as follows: “We would advise a thorough drenching of the trees with lime-sulphur at scale strengths for a dormant spraying to prevent the eggs from hatching, provided one is going to spray for the San José scale or the blister mite; we are not yet ready to recommend a spraying for the eggs of the leaf-roller alone. This application should be made as late as possible in the spring before the buds burst. We would advise a thorough spraying with arsenate of lead at the rate

of 2½ to 3 lbs. to 50 gal. of water, before the buds burst but while they are swelling or just as the tips begin to show green, and again before the flower buds open. These applications will also catch the bud-moth larvæ, which are serious pests."

The report concludes with brief notes on 2 closely allied species, namely, the oblique-banded leaf-roller (*Archips rosaceana*), and the ugly-nest leaf-roller (*A. cerasivorana*). A partial bibliography consisting of 41 titles is appended.

The alfalfa gall midge (*Asphondylia miki*), F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 147, pp. 4, figs. 6*).—This circular has been prepared in order to direct the attention, especially of alfalfa growers in the southwestern portion of the country, to the appearance of this foreign insect in the United States. It can not be predicted at the present time what injury this insect will cause in the United States, though it has not so far proved destructive.

Galls, from which this insect was afterward reared, were first found in limited numbers at Sacaton, Ariz., in June, 1909. They were found about Tempe and Phoenix, Ariz., in June, 1911, and at Tularosa, N. Mex., in July of the same year. A translation is given of the original descriptions of the gall as found in alfalfa fields in the vicinity of Vienna, Austria.

While but little definite information has been gained in relation to the pest, it apparently winters in the pods. So far as now known its breeding season during summer is rather short, as it has not been noticed earlier than late May or later than September. The source of its entrance into this country remains obscure, but the author suggests that it may be working its way from Mexico northward. That it is preyed upon extensively by parasitic insects, although the parasites are all new to science and have never been described, is thought to imply a rather long residence in this country. "The indications are that it is spreading over the alfalfa-growing sections of the extreme Southwest, but it does not necessarily follow from this that it will prove so destructive as have many other insects coming to us from across the Atlantic Ocean. . . .

"Mowing the alfalfa just as the plants are coming into bloom will doubtless keep the numbers of the midge much reduced, as this method tends to prevent development, and, therefore, to curtail increase in numbers."

Papers on insects affecting vegetables.—Arsenite of zinc and lead chromate as remedies against the Colorado potato beetle, F. A. JOHNSTON (*U. S. Dept. Agr., Bur. Ent. Bul. 109, pt. 5, pp. 53-56*).—This is a report of a series of experiments conducted in cooperation with the Virginia Truck Experiment Station in which the insecticidal value of arsenite of zinc and of lead chromate was compared with that of other arsenicals.

"The results obtained from the use of lead chromate were very unsatisfactory as compared with those in the case of other insecticides used. The lead chromate employed was in the form of a powder, and great difficulty was experienced in making it mix well with water, it having a tendency to settle quite rapidly, requiring constant agitation to keep it in solution. It adhered well to the foliage, and its color stood out quite prominently in contrast to the other plants. However, the young larvæ seemed to be able to feed on plants that were thoroughly covered with the material without receiving much injury.

"The arsenite of zinc employed was also in the powdered form. It is much lighter than lead chromate and remains in suspension in water much better. It adheres to the foliage very well and does not, so far as could be observed, burn or injure the plants in any way." In experiments with arsenite of zinc at the rate of 1, 1½, and 2 lbs., respectively, to 50 gal. of water, by far the best results were obtained where 2 lbs. of the arsenite was used. "Without doubt

an even greater amount of the arsenical might be used without injury to the plants and with correspondingly greater efficiency in killing the beetles."

**Papers on cereal and forage insects.**—The so-called "curlew bug" (*Sphenophorus callosus*), F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Bul. 95, pt. 4, pp. 53-71, pls. 4, figs. 6*).—This is a summarized account of the present knowledge of *S. callosus* and includes information received from correspondence and recent studies by agents of the bureau.

This beetle was first described by Olivier in 1807 from "Carolina." Bureau notes here presented, dating from 1880 to the present time, show it to have been the source of injury at various points in Virginia, North and South Carolina, Georgia, Oklahoma, and New Mexico. It seems to center in point of abundance in eastern North Carolina, extending southward to southern Florida, northward to Maryland, thence northwest to northwestern Illinois, southwest to extreme southeastern Arizona and northern Mexico, and eastward to the Gulf coast. It is essentially a lowland form as its food plants clearly indicate, swamp and other low-lying lands being particularly subject to attack.

In addition to the cultivated food plants, corn, rice, and peanuts, the species has been found to feed upon *Cyperus strigosus*, *C. vulpinoidea*, *C. esculentus*, *C. rotundatus*, *C. exaltatus*, *Tripsacum dactyloides*, *Panicum capillare*, and *Carex frankii*.

Life history notes are given, together with descriptions of the egg, larva, pupa, and adult. The egg period was found to vary from 4 to 6 days in June and July and from 6 to 8 days in September. In one case 58 eggs were secured from one female. In North Carolina the eggs appeared to be deposited from June 1 to September 20, or during a period of approximately 4 months. The eggs are placed in the corn plant above the roots. Upon hatching the larva works downward, through the center of the lower stem and into the main root or taproot and, unless this is entirely eaten away, probably finishes its development there. While the insect is not aquatic, it is capable of living and developing on submerged plants without suffering material inconvenience therefrom. In cornfields it is often found working several inches below the surface of soil thoroughly saturated with water. While the corn is injured by adults and larvae, attacks by the latter are by far the most fatal to the plant.

Studies conducted at Wellington, Kans., show that the larval stage may occupy from 37 to 41 days. The adult beetle is reported to have issued September 1 from a larva which transformed to a pupa August 22. "The adults evidently hibernate to some extent in corn in the chamber in which they have developed, but seemingly lower down than in the case of *S. maidis*. . . . The numbers found, however, were far too limited to indicate that this can be true of even the majority, the others probably wintering over either in or near the surface of the ground. . . . The beetles probably come forth from their hibernation quarters quite early in spring, as soon as the ground has become permanently warm from the spring temperature. . . . They evidently feed for a considerable time by puncturing the lower part of the stems of the plants. These punctures are quite different from the egg punctures, and the effect is often not so fatal as that occasioned by the downward burrowing of the larva. These punctures are usually made about or a little below the surface of the ground, the beetle evidently searching for a point where the stem is tender and succulent. If the punctures are made lower down on the plant just above the root, the result is a throwing up of a number of tillers or suckers from the roots, the main stem itself having a stalky appearance, with the result that no ears are produced."

An instance has come to notice which seems to indicate that the beetles can survive not only in fresh water but also in salt water. The author's attention

was called to the fact that where corn had followed cotton crops no damage was apparent but where the preceding crop had been corn, the damage was in many cases very severe, often resulting in a total loss of the crop.

The night hawk (*Chordeiles acutipennis texensis*) and the predaceous maggot of the robber fly *Erax lateralis* are mentioned as natural enemies of this beetle. It appears evident that the beetles winter in the fields where they develop and that crop rotation is effective in preventing serious injury.

**Progress and prospects of tick eradication, C. CURTICE** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 255-265, fig. 1; Circ. 187, pp. 255-265, fig. 1*).—In this paper the author briefly discusses the beginning of tick eradication, the results of 5-years' work, obstacles to progress, reasons for tick eradication, and prospects for the future.

In summarizing the eradication work it is stated that at the time of writing "there have been freed of ticks and released from quarantine 127 counties and parts of 20 counties out of 929 originally infected; 90 are in varying degrees of disinfection. Over one-seventh of the counties have been cleaned, and over one-fifth of all the originally infected counties have been worked in. About one-tenth of the counties now infected are being worked in and are partially clean."

**The use of arsenical dips in tick eradication, B. H. RANSOM and H. W. GRAYBILL** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 267-284, pls. 6, fig. 1*).—This paper is based upon the investigations previously noted (*E. S. R., 27, p. 84*).

**A new leakage gage, C. W. WOODWORTH** (*California Sta. Circ. 75, pp. 15, figs. 8*).—This is the sixth of the author's papers on fumigation studies (*E. S. R., 26, p. 561*).

A new method of determining the leakage in fumigation work, through the use of a leakage gage which the author has invented, is here described. This new gage consists of a tent clamp and a set of 3 tubes, 1 of brass ending in a nipple for attaching a rubber mouthpiece, and the other 2 of glass, along 1 of which is a scale so graduated as to show the percentage of leakage, and a small glass chamber of water with which the 3 tubes communicate. The graduated tube is closed at the top but has a passage to the clamp ring which allows air to pass through the tent cloth. The other glass tube is open at the top.

The method of determining leakage is as follows: The glass chamber is filled partly full of water and a double thickness of the tent is clamped into the clamp ring, the tester blows gently through the rubber mouthpiece on the brass tube until the water rises to the top of the open glass tube, then the percentage of leakage is read on the scale where the top of the water column reaches in the closed glass tube.

The theory upon which most methods of measuring leakage is based is that the rates of leakage of gas through different pieces of cloth will show approximately the same difference that is found between the rates of flow of air through these cloths when it is forced through under the same pressure. The method used in this apparatus is to measure the resistance to the passage of air presented by the cloth to be tested as compared with an opening of a known size. The scale is graduated between 0 and 100 per cent leakage by testing in the gage a series of metal disks containing holes of different known area and determining the ratio of their areas to the area of the clamp ring.

Pressure gages for determining leakage were found to be more practical than volume gages, a test tube gage being the simplest form of pressure gage. A suction gage, which was the most satisfactory form used in the laboratory, requires a special form of regulating clamp. The use of a tester enables one

to be sure of the proper adjustment of the instrument. A combined instrument, containing both tent clamp and gage, is recommended for field work.

Leakage through the weave of the cloth was found to be much more important than that through visible holes.

Other phases discussed are the method of stating leakage and leakage in torn tents.

### FOODS—HUMAN NUTRITION.

Economic results of cold storage, JAMES WILSON (*U. S. Dept. Agr. Rpts. 1911, pp. 25-34*).—A special investigation was undertaken by this Department, in which detailed information regarding the cold storage industry was collected by means of schedules submitted to the cold storage warehousemen, and prices were compiled from the literature of the subject for the last 30 years. The particular object was to secure data regarding fluctuations in prices before cold storage existed or was of considerable importance, and to compare such data with fluctuations in recent years during which the business has grown to large proportions. On the basis of the information collected, such questions are considered as the length of time commodities remain in storage, the principal months when they are received, the percentage held for longer than a year, the average length and the costs of storage, the tendency to uniformity of prices throughout the year, speculation, and stored goods as a percentage of consumption.

In 1910-11, 47 per cent of the fresh beef placed in cold storage during the year was received during September, October, and November; similarly, 59.8 per cent of the fresh mutton was received during August, September, and October; 59.2 per cent of the dressed poultry during November, December, and January; 70 per cent of the butter during June, July, and August; and 79.4 per cent of the eggs during April, May, and June. As regards delivery, "the important observation to be made is that the receipts into cold storage are entirely or very nearly exhausted by the deliveries within 10 months."

With respect to costs of storage, "it is evident that as the time of storage lengthens, the costs and their percentage of the wholesale price must be multiplied by the number of months. If the storage is for 15 months, for instance, the cost per pound ranges from 5.273 cts. for fresh mutton to 8.572 cts. for butter, and is 8.898 cts. per dozen for eggs; the costs for 15 months range from 36.5 per cent of the wholesale price in the case of butter to 57.5 per cent in the case of fresh mutton. For the average length of time in cold storage, as ascertained in this investigation, the actual costs are for fresh beef, 0.997 ct. per pound; fresh mutton, 1.564 cts. per pound; fresh pork, 0.35 ct. per pound; for poultry, 1.079 cts. per pound; for butter, 2.532 cts. per pound; for eggs, 3.505 cts. a dozen. The costs of storage for the average length of time are 7.9 per cent of the wholesale price for fresh beef; 17.1 per cent for fresh mutton; 3.2 per cent for fresh pork; 6.8 per cent for poultry; 10.8 per cent for butter; and 18 per cent for eggs. Approximately, the wholesale prices of the commodities mentioned are increased by cold storage to the extent of the percentages just given."

Cold storage has influenced considerably the relative monthly consumption of commodities and has made it more even throughout the year. "There has also been a change in relative monthly prices, due to cold storage. In the case of eggs the relative price has increased in the season of natural plenty and diminished in the period of natural scarcity. . . . In the cases of both butter and eggs the annual price level has been raised by cold storage, for a reason apart from the costs."

With respect to the tendency to uniform prices throughout the year, an examination of the data collected regarding the range of prices indicates "a tendency toward uniformity of prices with regard to butter, eggs, poultry, and fresh mutton, and a tendency away from uniformity with regard to fresh beef and fresh pork."

With regard to the extent of the cold storage enterprise, the report points out that "this business of storing foods has grown to such proportions that consumers have a rightful concern with its management for economic as well as sanitary reasons. From the returns made to this Department by the cold-storage warehousemen, it is inferable that the fresh beef, fresh mutton, fresh pork, poultry, butter, eggs, and fish received into cold storage in a year amounts to a weight of at least 1,000,000,000 pounds and very likely to a quarter of a billion more. The eggs received into storage in a year are approximately 13½ per cent of the farm productions; the fresh beef is over 3 per cent of the census commercial slaughter of cattle; mutton over 4 per cent of that slaughter of sheep and lambs; fresh pork 11½ per cent of that slaughter of hogs; and butter 25 per cent of the creamery production."

From the investigation as a whole, the following recommendation is made with reference to publicity: "This is no indictment of the men who keep foods in cold storage except in so far as they sometimes speculate, nor need they be indicted for offenses in order that the public economic interest in their business may be made to appear. . . . The man who places food in cold storage is somewhat in the situation of the man who forestalls the market. He may not attempt to do so, but the power may be a temptation.

"The affairs of such a business as this should have publicity. The public ought to know how much goods are in storage from month to month and what the movements of receipts and deliveries are.

"The food warehousemen should be required to send to Washington monthly reports containing the desired information. Here these reports could be promptly aggregated and the results could be given to the public on a previously announced day of the month, somewhat as the crop reports are."

An inquiry into the cost of living in Australia, 1910-11, G. H. KNIBES (*Noted in Jour. Soc. Statis. Paris, 53 (1912), No. 3, p. 163*).—Statistics regarding the expenditures of 212 Australian families with an average income of \$100 per month are here summarized. The weekly expenditures for food for individuals of different age and sex are found to stand in practically the same proportion to each other as the figures given by Atwater to represent the relative nutritive demands of individuals of different age and sex.

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul., 2 (1912), Nos. 2, pp. 17-32; 3, pp. 33-48*).—The first of these bulletins contains data regarding the registration of beverages, the examination of crackers, biscuits, and similar goods, miscellaneous food products, and proprietary articles, and a discussion of a number of matters relating to pure foods.

The second bulletin contains some data regarding the registration of beverages, the examination of kippered herrings from a corroded can with reference to the tin, lead, and zinc present, analyses of "crisco," a commercial fat, and canned goods, the examination of miscellaneous food products, and analyses of waters.

A paper by T. Sanderson reports a comparison of the milling quality of samples of hard red spring wheat and hard red winter wheat. The data showed that from a milling standpoint the winter wheat is superior to the spring wheat and produces the largest amount of flour per bushel, with the smallest loss in milling. The 2 types of wheat, it is noted, are very similar in their general

characteristics, so much so that they require about the same treatment during tempering and milling. The growing of some winter wheat is recommended.

A comparative test is also reported of the baking strength of northern grown hard red winter wheat and hard red spring wheat. The results showed that the spring wheat produced a bread slightly superior as regards absorption, baking strength, color, texture, and protein content of wheat and flour, the greatest differences being with respect to baking strength (loaf volume) and protein content. The results as a whole are not regarded as unfavorable to the winter wheats.

The bulletin also reports a test by R. E. Remington on the immersion refractometer as a rapid means of approximating the solids in vinegar (see page 112), and discusses miscellaneous pure food topics.

**Studies on wheat flour.—I, Influence of the concentration of hydrogen ions on the baking value of flour, H. JESSEN-HANSEN (*Compt. Rend. Lab. Carlsberg, 10 (1911), No. 1, pp. 170-206, figs. 4*).—**The well known fact that the acid content of flour exerts an influence, not only on the specific gravity of bread but even more on its general quality, led the author to the conclusion that there exists an optimal concentration of hydrogen ions for the baking value of flour in general, or, in any case, that such concentration is capable of explaining the different properties which make up the baking value of flour. To test this theory, he conducted a series of baking tests with different flours, the conclusions being drawn from the average for 12 loaves in each case. The work is not yet complete, but on the basis of that accomplished, the author presents the following conclusions:

The optimal concentration corresponds approximately to the expanding of hydrogen ions  $ph=5$ . For the fine flours it is slightly higher; for the poorer varieties slightly lower.

Of the different milling products from the same grain, the finest flour, that is, that coming from the central portion of the grain, presents the greatest acid, or the greatest concentration of hydrogen ions, while the bran, which is the least acid, presents the least concentration of hydrogen ions.

The various artificial methods of improving the baking quality of flour which have been advanced recently have practically no other effect than that of increasing the concentration of hydrogen ions in the dough.

Measuring the gluten extracted by washing is deemed of no value in determining the baking value of a flour.

**The proteins of rice, S. KAJIURA (*Bio-Chem. Jour., 6 (1912), No. 2, pp. 171-181*).—**The article reports unfinished studies on the proteins of rice, from which the following conclusions are drawn:

"The proteins of 'white rice,' as used for dietary purposes in Japan, consist only to the smallest extent of albumins and globulins. The amount of alcohol-soluble protein is practically negligible, thus distinguishing rice sharply from all other cereals hitherto investigated. The main protein of rice, oryzenin, belongs to the glutelin class (proteins soluble in dilute alkali). In its nitrogen partition it differs from wheat glutenin (the only other glutelin so far studied) very considerably."

**The toxicity of caffeine—an experimental study on different species of animals, W. SALANT and J. B. RIEGER (*U. S. Dept. Agr., Bur. Chem. Bul. 148, pp. 98*).—**The results are reported of an extended experimental study with rabbits, guinea pigs, cats, and dogs of the toxicity of caffeine administered by mouth, by subcutaneous injection, and injection in other ways. There is also a historical review of the literature of the toxicity of caffeine and a bibliography.

The report is the first of a proposed series, and it is pointed out that the conclusions are in some particulars to be regarded as tentative.

Quotations from the authors' summary follow:

"The toxicity of caffeine in the rabbit varies with the mode of its administration, being least when given by mouth and greatest by intravenous administration. The toxicity is from 15 to 20 per cent greater by subcutaneous injections than by mouth, but is about half of that when injected into the peritoneal cavity. . . .

"The resistance of the guinea pig to caffeine, as of the rabbit, is greatest when given by mouth. . . . The adult cat is less resistant than the guinea pig or rabbit to caffeine. . . . The minimum fatal dose for dogs was found to be the same by mouth as by subcutaneous injection and is almost the same as for the cat. The toxicity of caffeine varies in the guinea pig according to season of the year.

"Age is likewise a factor in the toxicity of caffeine, young animals being more resistant than the full-grown and older animals: this was shown in experiments on rabbits, cats, and dogs. The symptoms of caffeine poisoning also were different in puppies and in full-grown dogs. Different diets, such as carrots and oats, did not influence the resistance of rabbits and guinea pigs to caffeine. Low protein diet tends to decrease resistance to caffeine in dogs. Young growing dogs are less resistant to caffeine on a meat than on a milk diet. Caffeine is not cumulative in the rabbit or dog, even if administered for a considerable length of time. Some degree of tolerance may be induced in the rabbit under certain conditions, but not in dogs under the conditions of the experiments made in this investigation. . . . The toxicity of caffeine is probably increased under pathological conditions, since comparatively smaller doses were fatal to rabbits, cats, and dogs, when marked lesions not due to caffeine were found at autopsy. Glycosuria was observed in rabbits, guinea pigs, and cats when caffeine was given in sufficient amounts."

See also a previous note (E. S. R., 25, p. 470).

Coca cola (sirup), A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 232, 1912, pp. 11*).—A summary of the analyses of 68 samples of the sirup made to determine their cocaine and caffeine content is given. No trace of cocaine was found in any, while the amount of caffeine varied from 0.15 to 0.72 of a grain per ounce, the average being 0.60.

State and municipal meat inspection and municipal slaughterhouses, A. D. MELVIN (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 241-254, dgms. 4; Circ. 185, pp. 241-254, dgms. 4*).—Inasmuch, as is stated, only a little more than one-half of the total meat supply of the United States is subject to the Federal inspection, the need for State or local inspection is pointed out, and the problems of local inspection are discussed. The municipal or central slaughterhouses recently erected in Paris, Tex., and Nashville, Tenn., are described and plans and specifications given for a central abattoir and septic tank.

The hourly chemical and energy transformations in the dog, after giving a large quantity of meat, H. B. WILLIAMS, J. A. RICHE, and G. LUSK (*Amer. Jour. Physiol., 29 (1912), No. 4, Proc. Amer. Physiol. Soc., 24 (1911), pp. XXXIII, XXXIV*).—The experiments here reported were carried out in a calorimeter of the Atwater-Rosa type. A dog fed 700 gm. of meat at noon of the previous day was placed in the calorimeter chamber between 10 and 11 a. m., and his metabolism measured. At 12 m. the animal was given 1,200 gm. of meat and again placed in the apparatus. The heat production and other factors of metabolism were determined hourly for 20 hours.

"It was found that the direct and the indirect calorimetry agreed perfectly.

"It was found that the heat production rose largely, and that this increase in heat production was proportional to the nitrogen eliminated in the urine, and

was in no way proportional to the quantity of material present in the intestine. It was found that the carbon which was retained from the protein ingested must have been retained in the form of glycogen, since the absorption of oxygen during the different periods corresponded exactly with this assumption, whereas, if the carbon had been retained in the form of fat, the oxygen absorption would have been 10 per cent less than that found.

"Further experiments have shown that glutamic acid added to a standard diet does not increase the heat production in any way."

**Investigations on the digestion of milk—gastric digestion of casein, L. GAUCHER** (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 9, pp. 354, 355).—Continuing previous work (E. S. R., 26, p. 662), the author studied the digestion of artificially separated casein in a dog with a duodenal fistula. Comparing the results with those of normal human digestion, he concludes that the digestion of casein corresponds to the final stage of the digestion of milk. He summarizes the process of normal milk digestion as follows:

Of 7 gm. of casein absorbed with 250 cc. of milk, 4 gm. passes immediately from the stomach in a liquid state, and 1 gm. in the form of a loose clot, while the remaining 2 gm. contracts and hardens rapidly. Energetic gastric movements are necessary to reduce them to a purée, under which form they leave the stomach from 1 to 1½ hours after ingestion.

**Calcium absorption in the animal body from pasteurized and sterilized milk, J. ZIMMER** (*Ueber Kalkresorption im Tierkörper bei Verwendung von pasteurisierter und sterilisierter Milch. Inaug. Diss. [Univ.], Strassburg, 1911, pp. 12; abs. in Hyg. Rundschau, 22 (1912), No. 6, p. 364*).—Two dogs were fed with pasteurized, 2 with sterilized, and 3 with raw milk. The animals were killed from 2 to 2½ hours after the meal and the amount of calcium in the contents of various portions of the intestines was determined. The results do not indicate that these methods of treating milk greatly affect the amount of calcium assimilated.

**Studies on water drinking.—XII. On the allantoin output of man as influenced by water ingestion, L. T. FAIRHALL and P. B. HAWK** (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 4, pp. 546-550).—Continuing previous work (E. S. R., 26, p. 360), the authors conducted experiments summarized as follows:

"When the diet of a normal man was supplemented by 900 cc. of water per day the average daily output of allantoin . . . was 0.0135 gm. for a period of 13 days. Upon increasing the water intake to 3,450 cc. per day for a period of 5 days, the average daily allantoin excretion was increased to 0.0173 gm. This constitutes an approximate 20 per cent increase. The daily value for a 5-day final period on the original 900 cc. water ingestion was 0.0122 gm.

"The increase in the allantoin output accompanying water drinking may indicate that the oxidative mechanism of the organism has been stimulated through the introduction of the large volume of water into the body, and that purin material which would ordinarily have been excreted in some less highly oxidized form has been oxidized to allantoin and excreted in this form. This interpretation is strengthened by the finding in this laboratory of a decreased uric acid output after the water ingestion of the subject (man) had been considerably increased.

"In view of the fact that the above interpretation is contrary to the current views regarding purin metabolism in the human organism, the authors make the interpretation tentatively until further experiments may be completed."

**The utilization of yeast in the human organism, W. VÖLTZ and A. BAUDREXEL** (*Biochem. Ztschr.*, 30 (1911), No. 6, pp. 457-472; 31 (1911), No. 3-4, pp. 355-357; abs. in *Hyg. Rundschau*, 22 (1912), No. 4, p. 245; *Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 4, 174).—When 100 gms. of desic-

cated yeast from which the bitter principle had been removed by treatment with soda was added to a basal ration in a digestion experiment with a man. 86 per cent of the protein from the yeast was resorbed and 88 per cent of the energy utilized. The calculated physiological nutritive value was 74.8 per cent of the total energy. The coefficients of digestibility were organic substances 90, fat 70, cellulose 40, and nitrogen-free extract 100 per cent.

**The place of retention or reconjugation of the amino acids in the body,** A. WOELFEL (*Amer. Jour. Physiol.*, 29 (1912), No. 4, *Proc. Amer. Physiol. Soc.*, 24 (1911), pp. XXXVIII, XXXIX).—Dogs, which had been operated on a few days previously for Eckfistulae, were used in these experiments. Their hepatic arteries were tied, and solutions of amino acids introduced into their washed out intestines.

All the urine excreted was collected and the animals bled completely. The blood was defibrinated and centrifuged, and the serum thus obtained had its albumin removed and was otherwise prepared for formol titration to test it for an increase in its amino nitrogen content over normal serum. The ammonia and the amino nitrogen in the urines were determined.

"The small increases of amino nitrogen in the blood and the small increases of formol titratable nitrogen in the urines were far from commensurate with the amounts of amino acid shown by determination to have been absorbed by the intestine. . . .

"That the amino acids are not removed from the blood with the fibrin in the defibrination, or that some constituents of the plasma or the blood corpuscles are not responsible for their disappearance, was shown by control determination.

"Tissues other than the liver, intestinal mucosa, and blood cells can take up amino acids from blood plasma. Since the tissues in general seem to have such an avidity for amino acids, it is fair to suppose that in them the amino acids can be utilized for the regeneration of albumins."

**The physiology of phosphorus during growth,** A. LIPSCHÜTZ (*Pflüger's Arch. Physiol.*, 143 (1911), No. 1-3, pp. 91-98).—Basing his opinion on experiments with young dogs fed a diet low in phosphorus, the author concludes that the growing organism is able to make use of all available phosphorus, whether it is supplied in small quantities by the food or deposited in the less important organs of the body.

**Biological significance of casein phosphorus for the growing organism,** A. LIPSCHÜTZ (*Pflüger's Arch. Physiol.*, 143 (1911), No. 1-3, pp. 99-108).—The author conducted experiments with growing dogs whose food contained no phosphorus except that supplied by casein. In his opinion the work is too incomplete to be conclusive, but indicates that the growing organism can obtain the inorganic phosphorus necessary for its supply from the organic phosphoric acid resulting from the cleavage of casein.

**Microscopic studies on living smooth muscle,** E. B. MEIGS (*Amer. Jour. Physiol.*, 29 (1912), No. 4, *Proc. Amer. Physiol. Soc.*, 24 (1911), pp. XIV, XV).—The experiments reported were made with amphibians and were intended to throw light on the question whether smooth muscle cells decrease in volume during contraction; the results "confirm this view."

**The chemical constituents of the ash of smooth muscle,** L. A. RYAN and E. B. MEIGS (*Amer. Jour. Physiol.*, 29 (1912), No. 4, *Proc. Amer. Physiol. Soc.*, 24 (1911), pp. XV, XVI).—The smooth muscle of the bullfrog's stomach was analyzed for potassium, sodium, phosphorus, and chlorine, together with parallel analyses of the ash of striated muscles from the same frogs. "The work indicates that smooth muscle contains somewhat less potassium and phosphorus and somewhat more sodium and chlorine than striated muscle, but the differences are much less marked than has sometimes been supposed.

"The chemical work was supplemented with microscopic study of fixed and fresh samples of the tissue analyzed as 'smooth muscle,' and it was found that 70 per cent to 85 per cent of its volume was smooth muscle fiber; about 5 per cent, extraneous connective tissue; and the remainder, interstitial spaces between the muscle fibers."

### ANIMAL PRODUCTION.

**Chemical investigations on maize silage,** D. FERUGLIO and L. MAYER (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spicgata*, 3 (1909-10), pp. 65-90).—Analyses of green maize and silage are reported.

The green forage contained 79.295 per cent of water. The other constituents on a dry-matter basis were as follows: Crude protein 8.419, pure protein 4, ether extract 2.173, invert sugar 14.296, sucrose 2.511, amids 1.96, pentosans 20.686, cellulose 28.248, ash 7.05, undetermined obtained by difference 12.88, and acidity 1.777 per cent.

The silage contained 78.77 per cent of water. The other constituents on a dry-matter basis were as follows: Crude protein 8.562, pure protein 2.56, ether extract 5, invert sugar 4.701, sucrose 0.273, amids 1.1, pentosans 19.13, cellulose 27.758, ash 6.4, undetermined obtained by difference 20.171, and acidity 6.905 per cent.

**Ensilage of fodder, roots, and beet pulp.**—Use of lactic ferments, L. MALPEAUX and G. LEFORT (*Jour. Agr. Prat., n. ser., 20 (1911), Nos. 42, pp. 488-490; 44, pp. 549, 550; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 1, pp. 195-200*).—The authors report experiments in fermenting beet pulp, distillery pulp, sliced mangolds, beet leaves, and corn silage with the ferment known as lacto-pulp. In the majority of cases there was a loss in nutrient elements, but the food was kept free from putrid ferments and in a sound condition both from the dietetic and hygienic point of view.

**The actual state of our knowledge of silage,** D. FERUGLIO (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spicgata*, 3 (1909-10), pp. 55-63).—This is a review of recent investigations on this topic.

**On the composition of hay damaged by rain,** G. PATUREL (*Jour. Agr. Prat., n. ser., 23 (1912), No. 17, pp. 524-527*).—A number of analyses of damaged alfalfa, clover, and common hay showed a loss of from 15 to 35 per cent in dry matter. A feeding test also indicated a proportionate loss in nutritive value.

**Chemical analyses of licensed commercial feeding stuffs, 1911,** F. W. WOLL (*Wisconsin Sta. Circ. Inform. 30, pp. 98*).—This is a report of the feeding stuffs control for the year. Analyses are reported of oil meal, cotton-seed meal, cotton-seed cake, gluten feed, dried distillers' grains, hominy feed, wheat bran, standard middlings, flour middlings, red dog flour, germ middlings, mixed mill feed, rye feed, rye bran, wheat, oat, and rye middlings, barley shorts, buckwheat feed, buckwheat hulls, ground corn and oats, corn, oats and barley, dried brewers' grains, malt sprouts, alfalfa meal, mixed feeds, dent corn, sweet corn, corn cobs, ground oat hulls, crushed oats, wheat screenings, pigeon grass seed, flax screenings, salvage barley, salvage grain, cull beans, pea feed, pea hulls, corn silage, green corn, green oats and peas, sorghum refuse silage, alfalfa hay, clover hay, western prairie hay, and brush feed.

**Licensed commercial feeding stuffs, 1912,** F. W. WOLL (*Wisconsin Sta. Circ. Inform. 31, pp. 13*).—A list of licensed manufacturers of concentrated commercial feeding stuffs for the calendar year ending December 31, 1912.

**Results of the examination of stock feeds, B. L. PURCELL** (*Ann. Rpt. Dairy and Food Comr. Va.*, 3 (1910-11), pp. 126-146).—Analyses are reported of bran, ship stuff, hominy feed, corn-oil meal, corn meal, cracked corn, gluten feed, cotton-seed meal, oil meal, rye middlings, rye feed, shorts, wheat middlings, red dog flour, and mixed feeds.

**Kansas feeding stuffs law, E. H. WEBSTER** (*Kansas Sta. Circ.* 18, pp. 7).—This contains the text of the Kansas feeding stuffs law as revised in 1911, and an explanation of the law and the changes made in it.

**The world's greatest meat market** (*Breeder's Gaz.*, 61 (1912), No. 12, pp. 705, 706, figs. 2).—This article describes the methods of marketing at the Smithfield market, London, and discusses the dressed meat trade of Great Britain.

"Approximately a fifth of the meat sold at Smithfield is domestic product." "Occasionally a little American mutton dribbles into Smithfield, but like American beef it promptly loses its identity." "Pork is displayed in enormous quantities in Smithfield, but it is mainly a showing of pigs, Danish and Holland contributions predominating." "Despite the growing paucity of American product displayed at Smithfield, the big Chicago slaughterers are conspicuously in the trade. One hears much of American control, but the proportion of the market business transacted by others is overwhelmingly large."

**Miscellaneous information concerning the live-stock industry, J. ROBERTS** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1910, pp. 499-524).—This information includes a review of the live-stock market in 1910, meat prices at home and abroad, foreign trade in animals and animal products, legal standards for dairy produce, contagious diseases of animals in foreign countries, and a list of state live-stock sanitary officials.

**The live-stock industry of Honduras, W. THOMPSON and J. E. DOWNING** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1910, pp. 285-295, pls. 4, fig. 1).—A popular account of information obtained by representatives of this Department, who made a tour of Honduras in order to obtain information to enable the Department to determine whether or not the importation of cattle from Honduras could be permitted under the law which prohibits the importation of live stock which are diseased, or have been exposed to infectious diseases within 60 days before the exportation.

The country is considered a good stock country as a whole, but the stock kept is poor and the methods are primitive. Three-fourths of the cattle in the country are raised in the departments of Choluteca and Olancho. Although some improved breeds have been imported, the greater part of the cattle are descendants of original stock imported from Spain and resemble the old Texas cattle. Bananas have been found to be a cheap and satisfactory food for fattening. The chief drawbacks are the lack of established markets in the provinces, the tick, and transportation facilities.

It was concluded that as southern fever and the cattle tick are prevalent throughout Honduras the importation of cattle to the United States could not be permitted.

**Live-stock breeding in Uruguay, O. GUTH** (*Rev. Asoc. Rural Uruguay*, 40 (1911), No. 9, pp. 668-679; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, pp. 206, 207).—A general account of the cattle and sheep industry.

**Circuit breeding** (*Amer. Breeders Mag.*, 3 (1912), No. 1, pp. 57-62).—An editorial which discusses the method of organizing breeding circuits, and the results which have been obtained where they have been formed.

The principles of breeding and the origin of domesticated breeds of animals, J. C. EWART (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 125-186, pls. 7, figs. 7*).—This comprises lectures given at the Fourth Graduate School of Agriculture, 1910.

Under the principles of breeding the author discusses such problems as line breeding, inbreeding, cross fertilization, reversion, effect of environment, maternal impression, telegony, transmission of acquired characters, Galton's ancestral law, and Mendel's law.

As an illustration of crossing distinct types the author reports an experiment in crossing a Mexican dog of the Chihuahua breed and a West Highland terrier. Another experiment is cited to show how a loss of vitality resulted by inbreeding goats. Other experiments, and the author's views on the origin of domesticated cattle, horses, and sheep, have been previously noted from other sources. It is pointed out that a knowledge of the history of the origin and characters of the breeds of domestic animals is a great advantage to those who undertake breeding experiments.

In conclusion the author states that, in order to improve breeding stock, "breed the best to the best, but avoid crossing different strains and different types of the same strain, and, as a rule, avoid close affinities."

The ancestry of domesticated cattle, E. W. MORSE (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 187-239, pls. 3, figs. 8*).—This article includes lectures given at the Fourth Graduate School of Agriculture, 1910, and is a summary of the literature on this subject. There are brief historical sketches of the Bovidae, the genus *Bos*, and the cattle bred by the early inhabitants of Asia, Northern Africa, and Europe. There is a critical discussion of different extinct species which may be the possible ancestors of the domesticated breeds in Europe and America. The classifications of breeds proposed by the different authorities are given, and a bibliography is appended.

[Cattle in Jamaica], H. H. COUSINS ET AL. (*Bul. Dept. Agr. Jamaica, n. ser., 2 (1912), No. 5, pp. 27-49, pls. 13*).—An account of the introduction and present status of the zebu, Red Polls, Jerseys, and grade Guernseys and Jerseys which have been imported to the island of Jamaica.

Brazilian Caracú cattle, N. ATHANASSOF (*Estudo sobre o gado Caracú. São Paulo: Govt., 1910, pp. IV+155, pls. 15, figs. 95; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 6, pp. 1405, 1406*).—An account of the characteristics of different breeds of cattle in São Paulo. Methods of management, body measurements, and statistical data are given.

Cattle breeding in Latium, A. STAZI (*Bol. Quind. Soc. Agr. Ital., 16 (1911), No. 23, pp. 901-911; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 2, pp. 474-476*).—This contains information on the state of cattle breeding, meat prices, and slaughter weights.

Experimental studies on cattle and pigs carried out at the Royal Zootechnical Institute of Reggio Emilia, A. ROMOLOTTI (*Studi Sperimentali Compiuti sui Bovini e Suini al R. Istituto Zootecnico di Reggio Emilia. Reggio Emilia, 1911, pp. 1-30; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 2, pp. 471-474*).—These studies report data on the increase in weight of cows during 9 months of gestation, the weight of the fetus at birth in relation to the live weight of the mother, the birth weight of Simmental-Reggiano calves, the weight of Simmental and Swiss calves at 1 year, the state of the teeth in calves at birth, and related topics.

Studies of the nutrition of the pig, E. V. MCCOLLUM and H. STEENBOCK (*Wisconsin Sta. Research Bul. 21, pp. 53-86, figs. 5*).—This bulletin consists of

3 articles, namely, Notes on the Creatinin Excretion of the Pig; Nature of the Repair Processes of Protein Metabolism; and A Metabolism Cage for the Pig. The first 2 articles have been previously noted from other sources (E. S. R., 26, pp. 359, 364). In the third article the advantages of using the pig for metabolism experiments are pointed out, and the details for constructing a metabolism cage for pigs are given.

The production of "hothouse" lambs, E. S. SAVAGE and G. W. TAILBY, JR. (*New York Cornell Sta. Bul. 309, pp. 234-255, pl. 1, figs. 14*).—This presents the results of 8 seasons' experience in the production of "hothouse" lambs. Part 1 deals with the care, management, and methods of slaughtering as practiced at the station. Part 2 contains records of the flock and products obtained. Part 3 contains tabulated data on market quotations, birth weights, slaughter weights, gains made, cost of gains, and selling prices for each breed. Some of the results are summarized in the following table:

*Data on production of hothouse lambs.*

Breed.	Number of lambs.	Average birth weight.	Average gain.	Average gain per day.	Average selling price.
		<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>

Evolution of the standard bred, F. R. MARSHALL (*Amer. Breeders Mag., 3 (1912), No. 1, pp. 45-51*).—This article consists of historical notes, which illustrate the rôle of selection in the improvement of breeds. The author is of the opinion that speed is probably the result of many contributing factors which, when analyzed, may prove to be unit characters inherited in Mendelian fashion.

Great sires of a hundred years, W. GILBEY (*Live Stock Jour. Almanac [London], 1912, pp. 46-56, figs. 8*).—Brief notes on famous sires of the different breeds of horses and ponies which originated in Great Britain are presented.

The army remount problem, G. M. ROMMEL (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 103-124, pls. 5; Circ. 186, pp. 103-124, pls. 5*).—It is pointed out that although the mounted service of the U. S. Army is now being furnished in a fairly satisfactory manner with horses purchased and developed under the remount system, the price of remounts is high. The plan devised by this Department and the War Department, previously noted (E. S. R., 25, p. 374), to encourage the breeding of horses is deemed necessary, because horses of the proper type are not sufficiently numerous to supply the army in case of war, and the time may soon come when it will be difficult to supply those needed in time of peace.

Previous to the Civil War most of the horses bred in the United States were of the light type, but in the last 40 years the heavy draft horse has been bred for farm use. Although the number of horses has increased, the proportion suitable for remounts has appreciably decreased.

There is a brief account of the mounted service in the militia and of police in large cities. Specifications for saddle horses purchased in 1910 for the use of the New York mounted police, a brief account of the horse breeding work of this Department, and an outline of the plan for encouraging the breeding of horses for the army, are also given.

**The restricted climatic environment of horses,** C. E. WOODRUFF (*Jour. U. S. Cavalry Assoc.*, 22 (1912), No. 90, pp. 1086-1103).—The significance of size, immunity to disease, coat color, and skin pigments in adapting horses to different climates is discussed. It is stated that a military horse fit for campaigning in all climates can not be bred, as he must be able to live in the open with little or no shelter.

**Watering the heated horse,** W. P. HILL (*Jour. U. S. Cavalry Assoc.*, 22 (1912), No. 90, pp. 1017-1020).—It is maintained that it is a fallacy to believe that it is harmful for a heated horse to drink water, as large amounts may be drunk if the temperature of the water is not cold enough to chill the horse.

**Pigeon culture as an agricultural industry,** V. P. GONCHAROV (*Ezhcg. Dept. Zeml. [Russia]*, 1910, pp. 452-544, pls. 10, figs. 13).—The author describes the different varieties of pigeons, and discusses breeding, housing, feeding, and marketing. A bibliography of Russian and other publications, including periodicals devoted to pigeon culture, is appended.

**Domestication of the fox,** B. I. RAYNER and J. W. JONES (*Amer. Breeders Mag.*, 3 (1912), No. 1, pp. 37-45, figs. 3).—An account of the silver fox industry in Prince Edward Island, where there are at present about 80 ranches stocked with about 200 fine dark silvers, 300 silver-grays, and 400 light silvers, the total skin value amounting to about \$550,000, and breeding stock estimated at about \$1,500,000 at current prices. The methods of feeding, management, and sale of furs are discussed.

**Biological investigations on pregnancy,** E. ABDERHALDEN and M. KIUTSI (*Hoppe-Scyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 4, pp. 249-258).—A preliminary note on experiments in the use of biochemical methods for diagnosing pregnancy in horses, rabbits, and guinea pigs.

**The experimental production of the maternal placenta and the function of the corpus luteum,** L. LOEB (*Jour. Amer. Med. Assoc.*, 53 (1909), No. 18, pp. 1471-1474; *Med. Rec. [N. Y.]*, 77 (1910), No. 26, pp. 1083-1087; *Zentbl. Physiol.*, 24 (1910), No. 6, pp. 203-208; *Proc. Soc. Expt. Biol. and Med.*, 7 (1910), No. 4, pp. 90, 91; *Deut. Med. Wchnschr.*, 37 (1911), No. 1, pp. 17-21; *Arch. Entwickl. Mech. Organ.*, 31 (1911), pt. 3, pp. 456-478, figs. 2; *Zentbl. Physiol.*, 25 (1911), No. 9, pp. 336-343).—A series of studies on ovulation and related topics. The maternal placenta could be produced artificially in guinea pigs by the introduction of foreign bodies. The function of the corpus luteum was thought to be that of synthesizing the uterine mucosa and to prevent ovulation in pregnant animals. Also, by delaying the rupture of the follicle even in nonpregnant animals the sexual period is prolonged.

**The size of the cell as a factor in form and function of domesticated animals,** K. VON DER MALSBERG (*Arb. Deut. Gesell. Züchtungsk.*, 1911, No. 10, pp. 367, pls. 27).—Following a discussion of some biochemical, physical, and morphological characters of cells, the author gives the average measurements of the diameter of striated muscle fibers of horses, cattle, and sheep.

In his opinion there is a correlation between the size of the muscle cells and the different species, breeds, and types of live stock, although this is influenced more or less by food, climate, and other ecological factors. He, therefore, suggests the use of these average measurements as "histo-biological symbols" for the different types and breeds of stock.

**The false rib**, A. BORGEAUD (*Terre Vaud.*, 3 (1911), No. 50, pp. 455, 456; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 2, pp. 458, 459).—A critical discussion of the views of Bièler and Pagès, who consider that an abnormal number of floating ribs is a sign of a good dairy cow, but a fault to be avoided in draft and meat animals.

**Notes on heredity**, W. J. SPILLMAN (*Amer. Nat.*, 45 (1911), No. 536, pp. 507-512; 46 (1912), Nos. 542, pp. 110-120; 543, pp. 163-165; 545, pp. 309-312).—The author reviews the recent work of Doncaster, Morgan, Loeb, Gortner, and others who have reported investigations on inheritance in plants and animals, as previously noted.

**The general trend of the problems of development and inheritance**, A. GREIL (*Zool. Jahrb., Abt. Allg. Zool.*, 31 (1912), No. 3, pp. 303-518).—A discussion of the problems connected with embryology or the development of the individual, and inheritance or the development of the race.

**Darwinism and human life**, J. A. THOMSON (*London, 1911*, pp. VII+251, pl. 1).—This book contains a series of lectures, given before the South African Association for the Advancement of Science in 1909, and which treat principally of the factors concerned in variation and heredity. A bibliography of books on heredity, variation, and evolution is appended.

**The value of pedigree**, J. WILSON (*Live Stock Jour. Almanac [London]*, 1912, pp. 104-106).—The value of knowing the pedigrees of breeding animals is pointed out, although a long pedigree is no guaranty that invariably the offspring will possess the qualities of near or remote ancestors. Though not so stated, the applications of Mendel's law in breeding horses and cattle are illustrated by a number of examples, and formulated into general principles as follows:

"We now know that most characters that make stock what they are run in pairs, a masking and a masked character." "It is easy to eliminate a masking character, but difficult to breed it pure, and it is difficult to eliminate a masked character, but easy to breed it pure."

**A new method of proving Delbœuf's law**, H. HUGUET and A. LUOSTE (*Rev. Vét. [Toulouse]*, 36 (1911), No. 10, pp. 605-614; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, pp. 202-204, pl. 1).—A new method of proving mathematically that however large may be the number of individuals similar to itself, and however small the number of individuals different from itself, from which an isolated organism may arise, the time will arrive when the descendants that have varied will outnumber those that have not varied, providing the different generations breed in the same manner.

**On the general theory of the influence of selection on correlation and variation**, K. PEARSON (*Biometrika*, 8 (1912), No. 3-4, pp. 437-443).—This is a mathematical proof that certain formulas used by the author do not depend for their accuracy on the frequency being Gaussian in character.

"They are really peculiar to the general idea of the manifold linear variate  $u$  which gives the maximum correlation coefficient of an  $(n+1)$ th variate with  $n$  other variates. They do not involve any idea of continuity or any hypothesis as to the nature of the selected means, standard deviations, and correlations beyond the fundamental assumption that the selected population really exists inside the unselected population."

**The application of the correlation coefficient to Mendelian distributions**, E. C. SNOW (*Biometrika*, 8 (1912), No. 3-4, pp. 420-424).—Several criticisms are made of methods previously noted (E. S. R., 24, p. 374), and a demonstration of one is given to show that the method of finding correlation must be deter-

mined in each case according to the nature of the distributions dealt with, whereas some have applied all methods to all cases indiscriminately.

Supplementary tables for finding the correlation coefficient from tetrachoric groupings, P. F. EVERITT (*Biometrika*, 8 (1912), No. 3-4, pp. 385-395).—These tables were prepared to facilitate the determination of a correlation coefficient by the method of the fourfold table in those cases where correlation has a very high value.

### DAIRY FARMING—DAIRYING.

Dairying, K. STÖREN (*Meierilære. Christiania* [1911], pp. 282, figs. 118; rev. in *N. Y. Produce Rev. and Amer. Cream.*, 32 (1911), No. 13, p. 482).—A general treatise on dairying.

New queen of the dairy world, O. ERF (*Hoard's Dairyman*, 43 (1912), No. 14, p. 543, figs. 3).—An account of methods of feeding and other data concerning the Holstein cow, Banostine Belle De Kol, which is reported to have produced 27,404.4 lbs. of milk in 1 year.

Milking with machines, F. SCHNEITER (*Wiener Landw. Ztg.*, 62 (1912), No. 27, pp. 339, 340, fig. 1).—A brief description of different types of milking machines, with a discussion of their practicability for the dairy farmer.

A short method of computing dairy rations according to the net energy standards, H. E. VAN NORMAN (*Pennsylvania Sta. Bul.* 114, pp. 3-20).—This bulletin presents a short method of computing dairy rations according to the net energy standards. The ordinary methods of computing balanced rations take into consideration their composition only, while with the energy standard the rations are computed according to their ability to do work as measured by energy after deducting the losses in feces, gas, urine, and energy of digestion. This leaves the net energy available for maintenance and milk production.

Samples of rations, a convenience table for compounding grain mixtures, and a table of energy values of the more common feeding stuffs are given.

On the specific effect of feeding stuffs upon milk production, A. MORGEN (*Landw. Vers. Stat.*, 77 (1912), No. 1-2, pp. 17-31).—A brief report on an experiment with 3 sheep and 2 goats, with a review of previous work. All of these indicate that certain feeding stuffs exert a specific effect upon the yield of milk and the character of the milk fat.

The influence of organic and inorganic phosphorus compounds on milk secretion, G. FINGERLING (*Biochem. Ztschr.*, 39 (1912), No. 3-4, pp. 239-269).—Rations containing straw, blood albumin, molasses, peanut oil, starch, salt, and carbonate of lime were used in these experiments with 2 goats.

Neither organic nor inorganic phosphorus in the form of lecithin, phytin, casein, nuclein, nucleic acid, and disodium phosphates were found to have any specific effect upon the activity of the mammary glands as regards the amount of milk, percentage of milk constituents, or absolute percentage of lime or phosphorus content of the ash. The organic phosphorus produced no better results than the inorganic phosphorus, so that apparently animals can obtain their supply of phosphorus through inorganic as well as organic compounds.

Hypoplasia mammaria and the chemical composition of milk, U. SELAN (*R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata*, 3 (1909-10), pp. 33-38).—No appreciable difference was found in the chemical composition of milk in the diseased and normal quarters of 2 cows affected with congenital hypoplasia mammaria.

The effect of the presence of *Bacillus bulgaricus* and of *Bacterium lactis acidii* upon typhoid bacillus in milk, LENA R. POTTER (*Rpt. Bd. Health Conn.*, 1909-10, pp. 150-154).—Samples of sterile milk were inoculated with bouillon

cultures of the typhoid germs, and at the same time with either a culture of *B. bulgaricus* or *B. lactis acidi*, which had been recently isolated from sour milk.

As a result of the work it is concluded that the repressing influence of both the ordinary lactic organism and the organism of Metchnikoff upon the growth of typhoid bacilli in milk, if it occurs at all, is so slight as to be of no significance, and these organisms can not be depended upon for rendering safe milk which has been inoculated with typhoid fever germs.

The selective action of media on organisms of the coli group, and its bearing on the question of variation in general, C. REVIS (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 33 (1912), No. 17-19, pp. 407-428).—These experiments were made with milk in all cases except one. Ordinary milk was taken about 12 hours after milking and kept for 18 or 24 hours at a temperature of 20° C. and then examined, or else the milk was immediately examined and then kept for the necessary time and re-examined. One experiment was carried out with cow dung freshly excreted, and with a water dilution of it kept for 1 week at 20°. In all cases dilutions by tens were made down to 1:10<sup>5</sup>. One cc. of each after careful mixing was inoculated into tubes of bile salt glucose peptone water, and incubated for 18 to 24 hours at 37.5° anaerobically.

The results showed that the most numerous form is an organism coagulating milk and attacking lactose, saccharose, and adonitol vigorously. The other organism isolated on the same plate was evidently of the same variety, but much weaker in activity as the full fermentative power was not developed before 72 hours, whereas the other had exhibited its full effect in 24 hours. The results of the different forms are given, followed by a discussion of variation.

The following conclusions are drawn: "The types of coli-form organisms which appear on inoculation of dilutions of milk, etc., into bile salt glucose tubes are the result of a combination of mutual toxic action, acid development, and the nature of the medium. There is undoubted suppression of feeble organisms, particularly of those which can only produce acid and not gas from glucose.

"The aspect which at present obtains of the varieties of 'coli-form' organisms is an aspect determined by our media and its concomitants. Atypical forms of 'coli' are not degenerate forms, but stages in the variation of organisms belonging to the 'coli-typhoid' group."

A study of thirty-five strains of streptococci isolated from samples of milk, G. F. RÜDIGER (*Amer. Jour. Pub. Health*, 2 (1912), No. 2, pp. 107-109).—The cultural and morphological characters of streptococci isolated from fresh milk are presented in tabular form, and the following conclusions are drawn:

"*Streptococcus lacticus* can be differentiated from *S. pyogenes* by means of blood agar plates. The latter produces small colonies surrounded by a large zone of hemolysis, whereas the former produces green or greenish colonies with little or no hemolysis. *S. lacticus* has no sanitary significance as it is found in nearly all samples of clean, soured and fresh milk, and very often in the healthy milk ducts. *S. pyogenes* seems to occur but rarely in milk and is indicative of the existence of an inflamed condition of the udder of the cow. It seems likely, however, that these organisms may persist for some time after the inflammation has subsided, and that they may occur in mild inflammatory conditions."

An epidemic of septic sore throat in Baltimore and its relation to a milk supply, L. P. HAMBURGER (*Jour. Amer. Med. Assoc.*, 58 (1912), No. 15, pp.

1109-1111).—A preliminary report of an outbreak of throat affection, in which children were more frequently attacked and suffered more seriously than adults. The trouble was due to a streptococcus which contaminated the milk supply in a certain dairy during a brief period when a pasteurizer was disabled and unpasteurized milk was delivered.

Tests of the efficiency of pasteurization of milk under practical conditions, E. H. SCHORER and M. J. ROSENAU (*Jour. Med. Research*, 26 (1912), No. 1, pp. 127-158, fig. 1).—A study of the effectiveness of pasteurization by the holding process.

It was found difficult to regulate the temperature, and the milk was not heated uniformly until it had been running at least 7 minutes. There was more or less variation between the different layers of the milk, and it is also stated that the thermometer does not register the maximum or minimum temperature of parts of the milk that may pass.

Attempts were made to determine the efficiency of the apparatus in destroying pathogenic organisms, and the authors are confident that if milk reaches 140° F. and is held there for 20 minutes, tubercle, typhoid, and diphtheria bacilli will be killed, but a liberal factor for safety is required. Therefore, the best temperature to meet practical conditions is about 145°, and the milk should be held at this temperature for from 30 to 45 minutes. The single holding tank was not found as trustworthy as 2, 3, or 4 in series. The first tank acts as an equalizer, while the remaining tanks hold the milk at a uniform temperature. The necessity for official control of all pasteurizing plants is emphasized.

The pasteurization of milk, S. H. AYERS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 184*, pp. 44, figs. 32).—The information in this circular is compiled especially for dairy farmers and milk dealers. The topics discussed are the value of pasteurization, construction and arrangement of pasteurizing plants and machinery, care of machinery, controlling the process of pasteurization, handling and delivering pasteurized milk, and the cleaning of bottles and cans. The principal part of the work consists in the detailed description of different types of pasteurizers, holding tanks, retarders, and coolers. Comparative methods of the holding and flash process of pasteurizing are also discussed.

It is thought that pasteurizing in sealed bottles may become more popular in the future, the principal hindrance being the expensive equipment which is necessary, but it is believed that bottling milk while hot will make it possible to achieve practically the same results.

Some legal and practical aspects of a "bottled milk" regulation, J. O. JORDAN (*Amer. Jour. Pub. Health*, 2 (1912), No. 2, pp. 105, 106).—These are comments on the nullification by the supreme court of Massachusetts of the regulation of the Boston Board of Health, which prohibited the sale of milk or cream except in tightly closed or capped bottles or receptacles.

"This regulation went into effect on June 15, 1910, and had the endorsement of practically the entire community. Its enforcement had been carried on with such success that at the time of the above decision only 0.62 per cent of the daily supply was being sold in shops contrary to the provisions of the regulation. Furthermore, although the influence upon the public welfare from this change of handling can not be directly demonstrated, the facts obtainable indicate a decided improvement in the quality of shop milk from both chemical and bacteriological standpoints. Thus there were 27.8 per cent less court prosecutions based on low standard shop milk (i. e., deficiency in milk solids or fat) from June 15, 1910, to February 1, 1911, than for the corresponding period in 1909-10. Bacteriologically the gain is more remarkable, for despite the fact

that the regulation did not become operative until June 15, 1910, 77.8 per cent of the shop milk for the year 1910-11 complied with the board's regulation of 500,000 bacteria per cubic centimeter, while for the year 1909-10 only 54.74 per cent of the milk from stores conformed to this standard."

**The permit system of cream buying,** D. S. BURCH and W. F. DROGE (*Kansas Sta. Bul.* 181, pp. 397-440, figs. 3).—This bulletin, which has been prepared for persons engaged in receiving, sampling, and testing cream, gives a list of a cream-station equipment, methods of receiving and sampling cream, instructions for testing and paying for cream, milk, and skim milk, a discussion of cream-station difficulties, bacteria affecting milk and cream, and related problems.

**The temperature of pasteurization for butter making,** L. A. ROGERS, W. N. BERG, and B. J. DAVIS (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1910, pp. 307-326, figs. 3; *Circ.* 189, pp. 307-326, figs. 3).—The object of this investigation was to determine the proper temperature for pasteurization of cream for butter making as indicated by the destruction of bacteria and enzymes, and changes in flavor of the butter during storage. The pasteurizing was done in a continuous Jensen machine. The cream was cooled at once to churning temperature and churned within 3 hours.

From the results, presented in tabular form, it would seem that cream of a good quality can be efficiently pasteurized from the bacteriological standpoint by momentary heating to 71° C., but this is near the lower limit of safety, and if the bacterial content of the raw cream is high a temperature of from 74 to 77° C. must be used to secure uniform results. Peroxidase was destroyed at 77° and catalase and lipase at 70°. Galactase was much weakened by temperatures between 71 and 77°, but was not destroyed at 93°, the highest temperature employed.

An examination of the butter after storage indicated that pasteurizing at 66° or lower left in the cream some factor causing a deterioration of the butter which did not occur at 71° or higher. At 82° there was a cooked or scorched flavor to the butter, but this effect may be controlled to some extent by the skill of the butter maker. For the continuous pasteurization of sweet cream for butter making, therefore, a temperature of not lower than 74°, nor higher than 80°, is recommended, but it is stated that this applies to the pasteurizing of sweet cream in a continuous machine only. If cream is pasteurized in a vat or other holding device lower temperatures can probably be used.

**Better butter for Kansas** (*Kansas Sta. Circ.* 21, pp. 4, figs. 2).—This circular is written to show why cream is often of poor quality owing to bad management, and that good prices can be paid only for cream of superior quality.

**Italian cheese-marking regulations,** L. J. KEENA (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 82, p. 93).—This consists of extracts from the new Italian law relative to marking adulterated cheeses.

**Increasing creamery profits by handling special products and utilizing by-products,** S. C. THOMPSON (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.* 1910, pp. 297-306; *Circ.* 188, pp. 297-306).—This article contains practical suggestions to creamery operators for increasing their profits. The following topics are treated: The sale of sweet cream, manufacture of ice cream and casein, feeding of buttermilk to hogs, and handling eggs through the creamery.

**The necessity for controlling the bacterial content of pharmaceutical lactic ferments,** A. BERTHELOT and D. M. BERTRAND (*Ann. Falsif.*, 5 (1912), No. 42, pp. 164-171).—Analyses of samples of commercial lactic ferments revealed the presence of undesirable types of bacteria, and it is urged that government control is necessary.

## VETERINARY MEDICINE.

Book of veterinary doses, therapeutic terms, and prescription writing, P. A. FISH (*Ithaca, N. Y., 1912, 4. ed., rev. and enl., pp. 185*).—A fourth revised and enlarged edition of this pocket guide.

On the distribution of arsenic in the animal organism, SCHILLING and NAUMANN (*Arch. Schiffs u. Tropen Hyg., 16 (1912), No. 4, pp. 101-109; abs. in Sleeping Sickness Bur. [London] Bul., 4 (1912), No. 35, pp. 103, 104*).—In the investigations here reported arsenophenylglycin was administered to normal rabbits and to rabbits infected for a longer or shorter time with nagana. Each animal received a given dose and after a period of 24 or 48 hours was killed. The conclusions drawn are as follows:

“Twenty-four hours after intravenous injection the greater part of the arsenic is circulating in the blood. An infected rabbit excreted less arsenic than a non-infected rabbit. The blood serum contains considerably more arsenic than the blood clot. It is to be assumed that the blood cells of the circulating blood do not withdraw from the plasma any appreciable quantity of arsenic.

“The arsenic content of the organs varies apparently in an irregular manner. Absolutely, as well as relatively, the quantity of arsenic found is least in the brain and spinal marrow. Of the abdominal organs the kidneys contain relatively the most and the liver the smallest quantity of arsenic (5 out of 6 cases).

“If one takes into account the blood contained in the organs, by subtracting the arsenic contents of this from the arsenic found in the organs one gets the following results: The splenic cells always contain relatively large quantities of arsenic. Then follow the kidney cells. The arsenic content of the liver cells fluctuates within wide limits; it is always under that of the spleen and kidneys. The cells of the brain and spinal cord are free from arsenic.”

Stock poisoning by larkspur, C. D. MARSH (*Proc. Amer. Nat. Live Stock Assoc., 15 (1911), pp. 69-77*).—In the author's investigations it was found that cattle were never poisoned when they ate less than 30 lbs. of larkspur per 1,000 lbs. weight of the animal. An equal quantity of either the tall or low larkspur was required to produce the toxic effect. Cattle on the range were rarely poisoned by tall larkspur after the first week in July, whereas the low larkspur was poisonous from the time it starts in the spring until the flowers drop from it the first of July, it being a little more poisonous about July 1 than at any other time, due to the fact that the seeds are somewhat more poisonous than the other parts of the plant above ground. In experiments with horses it was found possible to get them to feed on larkspur, although on the open ranges they never eat it in any large quantity. It is stated that sheep feed on larkspur very readily and actually grow fat upon it, without the slightest harm.

It was found with experimental animals that where remedies were not applied about half of the affected animals recovered. It is stated that a remedy which results in the recovery of about 96 per cent of the affected animals has been found, a description of which will be published in a forthcoming report.

The regional lymph glands of food-producing animals, J. S. BUCKLEY and T. CASTOR (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 371-400, pls. 3, figs. 12; Circ. 192, pp. 371-400, pls. 3, figs. 12*).—This paper deals with the topographical anatomy of the lymphatic apparatus of food-producing animals.

“It is regrettable that a more absolute knowledge does not exist of the anatomical detail of this system in the various food animals, but an endeavor has been made to supply as much as possible of the general knowledge that could be gleaned from the various works that treat of this subject, together with a fair amount of original investigation carried out by the writers of this paper.”

The bactericidal substances of leucocytes.—Their mode of action, W. SPÄT (*Centbl. Bakt. [etc.], 1. Abt., Orig., 59 (1911), No. 2, pp. 178-182*).—As a result of this work it is pointed out that the bactericidal property of leucocytes is not a complex process such as occurs with sera. If leucocyte extracts are heated to inactivity and a portion of unheated extract is added no reactivation takes place.

Filterable virus, G. VALLILLO (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 9 (1911), No. 6, pp. 433-479*).—This is a critical review of the literature pertaining to the diseases caused by, or at various times supposed to be caused by, filterable viruses. It embraces both the fields of veterinary and human medicine, and also contains a discussion of the mosaic disease of tobacco.

Pathogenic bacteriology, C. E. MARSHALL (*Michigan Sta. Rpt. 1911, pp. 155-170*).—This is a brief account of the occurrence and work of the year with contagious abortion, infectious anemia in horses at Watersmeet, a disease of cattle near Uby, Huron County, malignant catarrh of cattle, granular vaginitis of cattle, avian tuberculosis, a disease of sheep in Clinton County, and worms in pigs. The tuberculin test proved inapplicable for chickens.

Annual report of the official veterinarians of Prussia for 1909, NEYER-MANN (*Veröffentl. Jahres-Vet. Ber. Tierärzte Preuss., 10 (1909 [pub. 1911]), pt. 1, pp. VI+132, pls. 17; 10 (1909 [pub. 1912]), pt. 2, pp. IV+169*).—The first part of this report consists of statistical data, discussions, etc., on anthrax, symptomatic anthrax, rabies, glanders, inflammation of the brain and spinal cord in horses, foot-and-mouth disease, lung plague, dourine, vesicular eruption in horses and bovines, scabies in horses and sheep, swine erysipelas, swine plague, hog cholera, chicken cholera, fowl plague, equine influenza, and strangles in the horse.

The second part deals with diseases that the law does not require to be officially reported, poisoning, general disturbances of nutrition, sporadic diseases, meat inspection, statistics relating to farm animals, etc.

Epizootics in the German Empire (*Jahresber. Verbr. Tierseuch. Deut. Reichs, 25 (1910), pp. VII+200, pls. 4, figs. 20*).—This is a report in regard to the distribution of epizootics in the German Empire during the year 1910.

Combating dysentery in calves, shoats, lambs, and foals, the gastric form of canine distemper, and other infectious stomachical and intestinal diseases with Ventrase, M. KLIMMER (*Deut. Landw. Presse, 39 (1912), No. 1, pp. 1, 2; Berlin. Tierärztl. Wchnschr., 28 (1912), No. 1, pp. 1-7*).—Ventrase, which is a colloidal silver preparation containing in addition a protective colloid, is given to new-born calves and other animals with the milk. Comparing the results thus obtained with check animals which received no Ventrase, the results are considered good. In one of the articles the germicidal value of this preparation for the intestinal tract of dogs was also studied.

The protozoan parasites of domesticated animals, H. CRAWLEY (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 465-498, pls. 6, figs. 13; Circ. 194, pp. 465-498, pls. 6, figs. 13*).—This is a popular account of the more common protozoan parasites of domesticated animals, including spirochetes, trypansomas, coccidia, piroplasms, sarcocysts, etc.

Fasciolopsis buski in Tonkin.—Its extreme rarity in man; its frequency in the hog, C. MATHIS and M. LEGER (*Bul. Soc. Path. Exot., 4 (1911), No. 4, pp. 200-202; abs. in Jour. Trop. Vet. Sci., 7 (1912), No. 1, pp. 149, 150*).—Of 248 head of swine examined at the abattoir at Hanoi, December 9-27, 1910, 16 harbored this fluke. As many as 20 were found in one animal.

Our present knowledge of the distribution and importance of some parasitic diseases of sheep and cattle in the United States, M. C. HALL (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 419-463, pls. 2, figs. 18; Circ. 193*).

pp. 449-463, pls. 2, figs. 18).—Following a brief discussion of the importance of parasitic diseases and the desirability of a study of distribution, etc., the author takes up the present knowledge of the distribution and importance of *Piroplasma bigeminum*, *Fasciola hepatica*, *F. magna*, *Multiceps multiceps*, *Thysanosoma actinioides*, *Haemonchus contortus*, *Oesophagostomum columbianum*, *Oestrus ovis*, and *Psoroptes communis ovis*, respectively.

Maps illustrating the distribution of these parasites and a bibliography of 33 titles are included.

**Cysticerci in American sheep, reindeer, and cattle, B. H. RANSOM** (*Science, n. ser.*, 35 (1912), No. 903, p. 636).—It is stated that the heart and voluntary muscles of sheep are frequently found by federal meat inspectors to be infested with cysticerci. While these cysticerci closely resemble *Cysticercus cellulosæ*, it is improbable that so many cases of this parasite would occur in sheep and be so comparatively rare in this country in hogs, which are the usual host.

Specimens of muscle cysticerci from Alaskan reindeer have been provisionally identified as the cysticerci of *Tania krabbei*, a tapeworm of the dog. Mention is made of some unusually high percentages of infestation of cattle with *C. bovis*.

**The determination of opsonins and bacterial tropins in antistreptococcic serum in horses. PRICOLO and BARTELLI** (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 34 (1911), Nos. 17, pp. 769-775; 18-19, pp. 817-826; abs. in *Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 7, p. 127).—Normal and immune sera were both found to contain substances capable of stimulating the phagocytosis of *Streptococcus equi*. In normal serum the substances are thermolabile, while in immune they are thermostable. They are present in larger amounts in the immune sera.

The opsonic index was found to fluctuate only between very narrow limits. It was greater in immune animals, but on injection of virulent organisms it was found to assume a negative phase. Accordingly, it is concluded that opsonins and bacterial tropins are different substances.

**In regard to the preparation of a precipitating anthrax serum, W. N. MARKOFF** (*Berlin. Tierärztl. Wehnschr.*, 27 (1911), No. 47, pp. 849-851).—By injecting rabbits with bacteria-free extracts of the anthrax bacillus it is possible to obtain a specific precipitating serum. The specific precipitating substances in the serum rise to a certain fastigium and then begin to vanish gradually. Physiological salt solution (0.85 per cent) is not recommended for preparing the antigen, as it produces a ring in the test with the specific serum itself. Bouillon can be used to better advantage.

**Treatment of anthrax by hypodermic injections of carbolic acid, G. CONDER** (*Jour. Trop. Vet. Sci.*, 6 (1911), No. 4, pp. 436-441).—In this article are recorded the results of treating 11 horses affected with anthrax by injections of carbolic acid. These were given every 2 to 4 hours at the beginning of the disease, and later every 6 hours until the temperature reached normal.

Seven of the cases recovered, and of the 4 animals which died 3 did not receive the treatment in the early stages of the disease. Two other animals which received no treatment died.

**The significance of agglutination for diagnosing blackleg and the fermenting capacity of the Bacillus anthracis symptomatici, with particular regard to differentiating between symptomatic anthrax and malignant edema, G. GROSSO** (*Berlin. Tierärztl. Wehnschr.*, 27 (1911), No. 35, pp. 621-625).—The results show that the highest fermenting capacity toward dextrose, lactose, saccharose, and glycerin was possessed by the *B. anthracis symptomatici*. The pseudo blackleg bacteria also fermented saccharose but not glycerin. The bacillus of malignant edema in a few instances decomposed glycerin,

but did not ferment saccharose. The *B. anthracis symptomatici* can be sharply distinguished from the edema bacillus on the basis of the fermentation test.

**Various methods for the diagnosis of glanders, J. R. MOHLER and A. EICHHORN** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 345-370, pls. 4; Circ. 191, pp. 345-370, pls. 4*).—After discussing the nature of glanders, particularly occult glanders, the authors give a description of practically all the tests thus far proposed for its diagnosis. The tests considered are physical examination, post-mortem examination, the auto-inoculation method, extirpation of the submaxillary gland, mallein reaction (subcutaneous), the ophthalmic test, cutaneous tests, the agglutination reaction, precipitation reaction, complement fixation test, and the combined complement fixation and agglutination tests. In all instances the methods of conducting the tests, the interpretation of the reactions, and their reliability are considered.

**On the sero-diagnosis of glanders, K. F. MEYER** (*Rpt. Govt. Vet. Bact. Transvaal, 1909-10, pp. 156-169*).—Substantially noted previously (*E. S. R., 25, p. 684*).

**The action of "606" upon glanders in laboratory animals, W. BENEWOLENSKY** (*Abs. in Vet. Rec., 24 (1911), No. 1201, p. 39*).—Rabbits, guinea pigs, and cats were artificially infected with glanders by means of a 3 days' culture of bacilli in glycerin agar, and were afterwards treated with one or two injections of Salvarsan ("606"). The glanders bacilli were introduced intraperitoneally in the case of 11 guinea pigs and 15 rabbits, and into the back of the neck in 12 cats, with 6 rabbits, 4 cats, and 4 guinea pigs as controls. In animals that died, in addition to post-mortem observation, cultural experiments were made with the heart's blood and from the liver and spleen. The author also tested the action of Salvarsan upon glanders bacilli in vitro.

The results showed a very clearly evident influence of Salvarsan upon the glanderous processes. The duration of the diseased process stood in definite relationship to the quantity of Salvarsan injected, especially in the case of rabbits. Animals which received a quantity of Salvarsan approaching the dose tolerated by the species died quickly, while those which received no Salvarsan died in due course from the ordinary progression of the disease. Animals which had received a smaller dose of Salvarsan, on the other hand, lived. In acute glanderous processes it is possible to sterilize the infected organs by means of Salvarsan.

**The treatment of tetanus, G. BACCELLI** (*Berlin. Klin. Wchnschr., 48 (1911), No. 23, pp. 1021-1024; abs. in Berlin Tierärztl. Wchnschr., 27 (1911), No. 35, p. 627*).—In galloping cases of tetanus heroic doses of antitetanin are without value, as they bring about a peracute condition.

**Influence of tetanus toxin and tuberculin upon autolysis.—Behavior of the lipoids, G. PESCI** (*Centbl. Bakt. [etc.], 1. Abt., Orig., 59 (1911), No. 2, pp. 186-188*).—The author sought to determine how the lipoids of autolysates of organs (sheep's liver taken after death) behave when brought into contact with tetanus toxin and tuberculin, with particular reference to the autolytic process. Controls were prepared of the autolysates containing no additions.

From the results it could be noted that a diminution in neutral fats and fatty acids and an increase in soaps took place in the case of the tetanus toxin, while in the tuberculin no appreciable changes could be observed.

**The passage of tubercle bacilli through the intact skin, H. KOENIGSFELD** (*Centbl. Bakt. [etc.], 1. Abt., Orig., 60 (1911), No. 1-2, pp. 28-68, figs. 3*).—The results indicate that tubercle bacilli pass through the skin via the hair follicles from which the hair has been cut or shaved off or removed with a depilator. No difference seems to exist between the infection caused by either

the human or bovine type of bacillus. The skin in no instance showed any visible microscopic changes, and seems to be greatly resistant to the infection.

**Tubercular septum in the nose of a bovine**, P. CHAUSSÉ (*Rec. Méd. Vét.*, 88 (1911), No. 24, pp. 580-585, figs. 3).—The results are given of a histopathological study of a case in which the nasal septum of an 8-year-old cow was affected. The animal had a generalized tuberculosis.

**Improved technique for diagnostic inoculation of animals with tuberculous material**, R. OPPENHEIMER (*München. Med. Wchenschr.*, 58 (1911), No. 41, pp. 2154-2166; *abs. in Jour. Amer. Med. Assoc.*, 57 (1911), No. 21, p. 1731).—The urine of the suspect was injected directly into the liver of guinea pigs. Specific lesions were found to develop in about 16 days.

**The subcutaneous bovotuberculin test for the diagnosis of bovine tuberculosis**, H. BAUSCH (*Die Subkutane Bovotuberkulinprobe für die Diagnose der Rindertuberculose. Inaug. Diss., Univ. Bern, 9111*, pp. 27; *abs. in Ztschr. Tuberculose*, 18 (1912), No. 5, p. 509).—As a result of examining 302 animals in an abattoir at Darmstadt, Germany, the author finds that the tuberculin test when used subcutaneously yields better results than those obtained with tuberculin. A previous eye test will have no influence upon a subsequent tuberculin reaction, but it must be conducted after the subcutaneous injection.

**The vaccination of cattle against tuberculosis**, E. C. SCHROEDER ET AL. (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910*, pp. 327-343; *Circ. 190*, pp. 327-343).—Previously noted from another source (*E. S. R.*, 25, p. 288).

**The medicament treatment of piroplasmiasis**, E. MEULEMAN (*Rev. Gén. Méd. Vét.*, 19 (1912), No. 23, pp. 365-380).—This is a review of recent work.

**Vaccination against bovine piroplasmiasis**, J. LIGNIÈRES (*Rev. Gén. Méd. Vét.*, 18 (1911), No. 213, pp. 489-506; *abs. in Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 59-63).—The author claims to have shown that animals which are very resistant to *Piroplasma bigeminum* may be very susceptible to a new piroplasm which he has named *P. argentinum* and that the latter may even prove fatal.

Blood taken from diseased cattle at a time when it contained a maximum number of parasites and kept at from 5° to 8° C. for 30 days, when injected intravenously, frequently caused a mild form of the disease, which was followed by immunity. The parasites present in this blood were found to be smaller than normal, spherical, and apparently multiplying. An intravenous injection of 10 cc. of this blood caused about the seventh day a general reaction which lasted for 1 or 2 days. This first vaccine retained its vitality for at least 8 days.

The methods of preparing the vaccine from blood containing the *P. bigeminum* by desiccation or freezing can not be applied to the *P. argentinum*, because this parasite retains both vitality and virulence after freezing. Since the introduction of the method 23,000 animals have been vaccinated.

**Some results of cattle-tick eradication** (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 196*, pp. 4).—This is a summary of the replies received in response to a series of questions sent out in an effort to secure direct evidence from cattlemen and farmers regarding the benefits to the cattle industry of the South which are being derived from the tick-eradication work carried on in cooperation between the Bureau of Animal Industry of this Department and the various States within the quarantined area.

**The etiology of pleuro-pneumonia**, E. J. MARTZINOVSKI (*Ann. Inst. Pasteur*, 25 (1911), No. 12, pp. 914-917, pl. 1).—The author here reports studies commenced in 1909 which have led him to conclude that pleuro-pneumonia is caused by a minute gram-negative, polymorphous, nonmotile bacterium, to which he gives the name *Coccobacillus mycoides peripneumoniae*. A magnification of 1,000 diameters is necessary in order to distinguish it clearly.

**Parturient paresis (milk fever) and eclampsia; and the internal secretion of the mammæ as a factor in the onset of labor** (*Kentucky Sta. Bul. 160*, pp. 83-104, pls. 9; *Jour. Infect. Diseases*, 10 (1912), No. 2, pp. 226-232, 233-243, 244-247, figs. 13).—This bulletin consists of 3 papers.

*Parturient paresis (milk fever), and eclampsia; similarities between these two diseases*, D. J. Healy and J. H. Kastle (pp. 83-90).—In this first paper the symptoms of parturient paresis and eclampsia are discussed and the similarities between the 2 diseases pointed out. A normal clinical urinalysis, based upon 100 urinalyses of the dairy cow covering a period of 3 winter and 3 summer months, is described, together with the urinalyses of 3 cases of parturient paresis. Since none of the 3 cases observed during the year succumbed, the finer pathological changes occurring in parturient paresis have not been established.

The theories of the cause of the 2 diseases are next discussed. "That the disease is due to a toxin elaborated in the udder, as the result of its own metabolism preceding normal milk production, there can be no reasonable doubt, and that the success of the modern treatment is due to preventing, by means of pressure, the absorption of this toxin seems most highly probable.

"We are of the opinion that eclampsia is due to a similar toxin elaborated by the breast in a similar manner, and would strongly recommend, as the most promising treatment, dilatation of the breasts with oxygen or sterile air, accompanied by vigorous massage of the breasts, or forcible compression of them by means of a properly applied bandage, at the same time using whatever medical measures may be indicated."

*The toxic character of the colostrum in parturient paresis*, J. H. Kastle and D. J. Healy (pp. 91-100).—In this second paper the authors report tests made of the effect upon the guinea pig of injections of the first colostrum of cows suffering from parturient paresis, the first colostrum of the normal cow, fresh milk from the station herd, the urine of the normal cow and the first urine of a cow suffering from parturient paresis, normal salt solution (0.85 per cent NaCl), and the aqueous solution of certain residues from colostrum and milk left after precipitating the colostrum and milk with dilute acid, and evaporating, respectively.

"It is evident from these results that normal salt solution, fresh milk from normal cows, the colostrum of normal cows, and the urine of a healthy cow cause no serious disturbances in the normal guinea pig, when injected into the peritoneal cavity. The injection of the colostrum of normal cows invariably caused a diarrhea in healthy guinea pigs, male and female, from which they gradually recovered after a few days. . . .

"On the other hand, death resulted from the injection of the colostrum of the cow having parturient paresis, and the post-mortem and microscopical examinations of the organs of the 4 guinea pigs that were thus killed showed the same pathological degenerations and changes that are characteristic of eclampsia. Unfortunately, but little if anything seems to be known regarding the micro-pathology of parturient paresis in the cow. We have shown, however, that cows recovering from an attack of this disease invariably show a nephritis. Our results with the colostrum of the cow suffering with parturient paresis certainly go to show the presence therein of some substance toxic to guinea pigs and certainly point to the udder and the mammary glands as the place of origin of the toxins or internal secretions producing parturient paresis and eclampsia respectively. The fact that the urine of the cow with parturient paresis causes such a profound diuresis in the guinea pig also points to the presence of toxic substances in the urine of animals so affected, and indicates that these toxins are not entirely destroyed in the tissues of the cow, but are in part at least, and

it may be in somewhat modified form, excreted by the kidneys. The fact also that the colostrum of the cow during an attack of parturient paresis invariably caused an abortion in pregnant guinea pigs is a matter of considerable physiological significance and will be discussed more fully in the following paper."

*The internal secretion of the mammae as a factor in the onset of labor*, D. J. Healy and J. H. Kastle (pp. 101-104).—In this third paper the authors report experiments in which they found that the colostrum of the normal cow, as well as of the cow suffering from parturient paresis, contains a substance or substances, capable of bringing about abortion in pregnant guinea pigs. "The substance or substances in the fresh colostrum of the normal cow which excite the pregnant guinea pig to premature labor, withstands heating to boiling for a short time. In this respect it is similar to the hormones and differs from the soluble ferments and many toxins."

**An unusual cause of udder disease**, L. A. KLEIN (*Amer. Vet. Rev.*, 41 (1912), No. 1, pp. 30-37).—The author describes an affection in which the skin of the udder, especially about the base of the teats, was irritated, dry, stiff, scaly, and sometimes swollen or thickened, while the milk of affected animals contained small flakes and white jelly-like clumps. At the time the cows were first examined only a few animals were affected but the number gradually included 90 per cent of the cows of a large dairy herd, clumps and flakes being so numerous that the cotton strainer was clogged and the milk would not pass through. In many instances small scabs were present, indicating the previous existence of a crack or fissure, and in some cases small abrasions or excoriations were present. The condition resembled in all respects a mild acute or subacute inflammation of the skin. Of the 48 cows showing the milk changes or teat symptoms, indicating the presence of catarrhal mastitis, 30 also exhibited these alterations in the skin covering the base of the teat."

The author's investigations showed the disease to be due to the exposure of the wet udder to cold, it having been the practice to wash the croup, buttocks, flanks, the legs (inside and out, down to the claws), the tail, and the udder with a mild disinfectant solution. "The udder trouble began about the middle of November, just after cold weather had begun. There were more affected cows in the end of the stable where the doors were frequently opened and kept partly opened for ventilation than in the other end where they were almost constantly closed. The irritated condition of the skin observed on the udders was just at the point where fluids placed on a clipped udder would collect by gravitation, and which, therefore, would remain wet longest."

The application of excessive quantities of water in cleaning the cows was replaced by dry brushing, using water only when necessary, wiping the udder with a cloth dampened with a 2 per cent solution of sodium carbonate, and then anointing with a small amount of vaseline. This, together with the administration of 3 drams of bicarbonate of soda and 1½ drams each of sodium sulphate and potassium acetate upon the feed twice daily, resulted in the recovery of the animals.

**Primary splenomegaly in sheep**, L. E. DAY (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 415-418*).—Splenomegaly as a distinct pathological process was first described in 1882, but so far as the author has been able to determine, has not been reported in the lower animals. An examination, both macroscopic and microscopic, made of an enlarged spleen and the liver from a sheep, which were received for diagnosis from one of the large slaughtering establishments in Chicago, is here reported in detail. The changes in the tissue were so characteristic that a diagnosis was made of primary splenomegaly.

**The preparation of hog cholera serum in Hungary**, A. EICHORN (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910, pp. 401-413, pls. 2, figs. 6*).—This is a

description of the apparatus and methods for preparing hog cholera serum in use at the government laboratory at Kobánya, a suburb of Budapest, Hungary. The process followed is essentially that devised by this Department, with certain modifications in details and apparatus. The table on which hogs are placed for bleeding, apparatus used in bleeding hogs, stall for securing hogs for inoculation with virus, stand for securing hogs for bleeding from the tail, apparatus for siphoning serum after centrifugalization of blood, and apparatus for filling the bottles with serum are described. The directions for the use of the serum are given, and the results obtained in its use, the selection of hogs for the production of serum, experiments with the simultaneous method of inoculation, the disposal of meat of hogs used in serum production, and price of serum, etc., are briefly discussed.

Some observations on the clinical symptoms, prophylaxis, and treatment of distemper, J. P. MCGOWAN (*Vet. Jour.*, 68 (1912), No. 439, pp. 7-17).—The author again describes an organism (E. S. R., 24, p. 787) which is "a gram-negative bacillus, and which shows, when stained by carbol thionin, polar staining or a constriction in the middle. Its length varies from  $2.3 \mu$  to  $0.5 \mu$ , and its breadth from  $0.5 \mu$  to  $0.4 \mu$ ." Its size is particularly variable "when grown in glycerin agar, assuming an almost coccal form." It is only slightly motile, has flagella, and forms no spores. The growth on the surface of agar is very characteristic, showing at the end of 24 hours hardly visible dewdrops, which enlarge very rapidly during the next 24 hours and assume the size of pin-heads which are raised above the surface of the medium and have a porcellaneous appearance with some opalescence. The growth is more rapid on blood agar. The organism renders litmus milk alkaline and produces no gas in saccharine substances and related bodies. As regards pathogenicity, it produces "typical distemper with the rise of temperature with the nasal discharge, eye symptoms, and later 'chorea' and distemper rash. It was produced in one puppy by pouring a culture of the organism down its nose; in another pup a much milder form of the disease was produced." It was only lethal for mice.

The author divides distemper as follows: "(1) Uncomplicated distemper; (2) complicated distemper, [with] subgroups, viz. (a) complications due to spread of infection by the distemper organism to various parts, (b) complications due to added infections by organisms other than the distemper organism, (c) complications due to toxins, (d) complications due to causes other than above; (3) mixtures of the above groups."

These forms are discussed, together with the prophylactic and curative treatment of the disease.

Further studies on the *Bacillus bronchicanis*, the cause of canine distemper, N. S. FERRY (*Amer. Vet. Rev.*, 41 (1912), No. 1, pp. 77-79).—Since the publication of the article previously noted (E. S. R., 24, p. 285), it has been found that the disease due to *B. bronchicanis* may be more widespread among animals than has been thought to be the case. In studies made during the course of an outbreak among laboratory animals, it was found that although the symptoms differ somewhat in various animals, yet the primary cause without a single exception was due to this organism.

"In nearly 100 per cent of the cases the *B. bronchicanis* was found at autopsy in pure culture in the lower trachea. In but a very few of the cases was there any sign of a nasal discharge or any abnormal condition of the eyes. The majority of the rabbits showed symptoms of distemper, commonly called, in the rabbit, 'snuffles,' while but 2 or 3 of the guinea pigs were thus affected, and

none of the monkeys. Only one of the animals, a monkey, had shown signs of a cough, which animals gave the *B. bronchicaris* pure in the trachea and blood."

Since the organism attacks other animals besides the dog, the author proposes to change the name to *Bacillus bronchisepticus*.

Contribution to the study of epizootic lymphangitis, M. L. TEPPAZ (*Jour. Trop. Vét. Sci.*, 7 (1912), No. 1, pp. 53-61).—*Leucocytozoon piroplasmoides* was found in the pus of all the buds of 100 horses that were examined, to the exclusion of all other organisms.

An anatomico-pathological and experimental study of pernicious anemia (typho-anémie infectieuse) of the horse, G. FINZI (*Rev. Gén. Méd. Vét.*, 18 (1911), No. 216, pp. 681-687, figs. 2).—The author reports studies made of the lesions found in the liver, kidneys, and spleen, together with studies of the blood.

A contribution to the study of infectious paraplegia of the horse, A. MOULUN and A. M. OYTELA (*Bul. Soc. Cent. Méd. Vét.*, 89 (1912), No. 6, pp. 140-145).—This paper consists of clinical and bacteriological notes made during an epidemic at Maizières, France, in November, 1911.

A report upon the permanent value of the roaring operation as evidenced by the present condition of 100 horses which have been satisfactorily operated upon for roaring from 18 months to 2½ years ago, F. HOBDDAY (*Vet. Jour.*, 68 (1912), No. 442, pp. 207-218).—The author, who has operated for roaring upon more than 520 individual horses, finds that the beneficial results obtained are lasting.

## RURAL ENGINEERING.

On the measurement and division of water, L. G. CARPENTER (*Colorado Sta. Bul.* 150, pp. 3-48, figs. 5).—This is a revision of Bulletin 27 of the station, previously noted (E. S. R., 6, p. 485), to which is added a set of tables showing the discharge over right-angled triangular weir notches, and a discussion of the use of rating flumes and of Kutter's formula for determining the flow in canals.

[Investigation of the regulation of hydraulic works in the United States of America], R. TAVERNIER (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr. [France]*, 1909, No. 39, pp. 397-447).—This report deals with the developments in the United States relative to laws regulating interior navigation, irrigation, water power, and the conservation of these natural resources. In connection with this report are a number of reports and articles on irrigation, hydraulics, hydroelectric works, and reclamation in various parts of the United States.

An experiment station for irrigation, M. CONTI (*Agr. Colon. [Italy]*, 6 (1912), No. 1-2, pp. 29-37, figs. 6).—This article deals with the need and importance of irrigation in Argentina, briefly discusses institutions for experimental agricultural hydraulics, and describes the irrigation experiment station conducted by the Faculty of Agronomy of the National School of Agriculture at Buenos Aires and its work.

Irrigation in Egypt, J. BAROIS (*Les Irrigations en Égypte. Paris, 1911, 2. éd., rev. and enl., pp. XVI+422, pls. 17, figs. 90*).—This publication deals with irrigation works and irrigation administration and legislation in Egypt, and discusses the topography and character of the soil, inundation, irrigation of the Delta and of middle Egypt, drainage of irrigated land, and construction and maintenance of dams and canals. A description is given of the inundation basins, of different irrigation works, and of agricultural developments in Egypt.

Irrigation and drainage, L. A. B. WADE (*Rpt. Dept. Pub. Works N. S. Wales, 1911, pp. 33-67*).—This report covers the operations and expenditures

of the irrigation and drainage branch of the department of public works of New South Wales in 1911, embodying the reports of the assistant engineers on sewerage construction, swamp drainage and water conservation, irrigation, artesian boring, and river discharge observations and records.

Proceedings of third annual drainage convention held at Wilmington, N. C., November 22, 23, 1910, J. H. PRATT (*N. C. Geol. and Econ. Survey, Econ. Paper 21, 1911, pp. 67, pls. 4*).—This paper gives the proceedings of the third annual drainage convention held in North Carolina in 1910, a copy of the North Carolina drainage law, North Carolina supreme court decisions regarding the validity of drainage bonds, and a paper on Tile Drainage by J. R. Haswell, of the Drainage Investigations of this Office.

Reclaiming land by drainage, H. R. McVIGER (*Manfrs. Rec., 61 (1912), No. 15, pp. 51-53, figs. 3*).—This article deals with the development of levee and drainage districts in the lower Mississippi Valley, and discusses several drainage projects in this locality intended to drain and make fit for cultivation some 2,500,000 acres of land.

[Drainage in land reclamation] (*Manfrs. Rec., 61 (1912), No. 11, pp. 49, 50, figs. 4*).—A drainage development work in Florida by which it is intended to reclaim a tract of 118,000 acres of land is described.

[A drainage plan in Louisiana], W. S. WHITE (*Rice Jour. and South. Farmer, 15 (1912), No. 5, p. 3, fig. 1*).—A description is given of a plan for draining an area of 41,000 acres of land in Louisiana. This work involves about 38 miles of ditch, requiring about 653,400 cu. yds. of excavation. Specifications for clearing and excavating are given.

Drainage, E. J. WATSON (*Ann. Rpt. Comr. Agr., Com. and Indus. S. C., 8 (1911), pp. 101-111, fig. 1*).—This report deals with the South Carolina drainage act, surveys and preliminary examinations of drainage projects in the State, the organization of the National Drainage Congress, and the South Carolina State Drainage Association, and the growth of irrigation developments in the State.

Cost and methods of clearing land in western Washington, H. THOMPSON (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 239, pp. 69, figs. 25*).—This bulletin represents cooperative studies with the Washington, Wisconsin, and Minnesota stations, and a portion of the work reported has been previously noted (*E. S. R., 26, p. 787*). It calls attention to the extent of waste stump land in western Washington and deals with the methods and costs of clearing this land for farming purposes and for general use, briefly discussing the methods for converting stump land into pasture and describing and discussing the methods and apparatus required for removing stumps by heavy blasting, by a stump puller with and without blasting, by a donkey engine, and by char-pitting and burning. Cost data are given for removing stumps of varying sizes under varying conditions by each of the above methods.

It is concluded that a man without capital can not hope to clear, in a short time, a large enough tract of land upon which to support a family. Under the most favorable conditions and with the lightest clearing ground, the cheapest rate at which logged-off land can be prepared for the plow is \$50 per acre and the maximum is about \$150 per acre. The method of clearing by donkey engine in connection with blasting, char-pitting, and burning seems to be the cheapest, most efficient, and most serviceable method, especially when the work is done on a large scale.

Highway engineering, A. H. BLANCHARD and H. B. DROWNE (*New York and London, 1911, 1. ed., pp. X+299*).—This volume gives a large mass of information relative to the construction and maintenance of roads and pavements, as presented at the Second International Road Congress, held at Brussels, 1910.

Science in the service of highway construction, C. RICHARDSON (*Pop. Sci. Mo.*, 80 (1912), No. 4, pp. 326-337, fig. 1).—The author outlines the development of modern methods of highway construction and shows how science has aided therein.

Good roads, E. J. WATSON (*Ann. Rpt. Comr. Agr., Com. and Indus. S. C.*, 8 (1911), pp. 121-127, pls. 2, fig. 1).—This report deals with the development of road construction, maintenance, and administration in South Carolina, and gives tabulated data on the total mileage of public roads in the State, the methods of construction and improvement, and the expenditures in money and labor.

Proceedings of the second annual convention of the Inter-Mountain Good Roads Association, Pocatello, Idaho, June 22-24, 1911 (*Proc. Inter-Mountain Good Roads Assoc.*, 2 (1911), pp. 64).—These proceedings contain discussions of road construction, maintenance, and administration in general, and reports of road work done in the different States belonging to this association.

Report of the State Highway Commission of Minnesota, 1909-10 (*Rpt. Highway Com. Minn.*, 1909-10, pp. 31, figs. 11).—This report presents general investigations of road conditions, building material, and construction and maintenance methods, and includes the state engineer's report on the roads of the State.

French experiments with tarred roads, W. H. HUNT (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 103, p. 430).—Attention is called to the extent of tarred roads in France, the essentials of good construction, and the results of experiments with the dust from tarred roads, divers tar and oil emulsions, and deliquescent salts used in road surface.

Highway bridges and culverts, C. H. HOYT and W. H. BURR (*U. S. Dept. Agr., Office Pub. Roads Bul.* 43, pp. 21, pls. 14, figs. 3).—This is a revision of Bulletin 39, previously noted (E. S. R., 25, p. 891), and has for its purpose the pointing out of some of the important fundamental principles that govern operations necessary to secure properly designed highway bridges and culverts, together with some facts relating to their construction. A systematic course of procedure in bridge and culvert work is outlined and discussed, as consisting of the following steps: Securing the services of a capable bridge engineer, testing the foundation to determine its suitability, bearing power, and economy, determining the location and making the profile, determining the proper loading, and the making of accurate and economic designs and plans and cost estimates.

Plans showing details of structures are also given.

Culvert practice in road building in connection with drainage ditching in Minnesota (*Engin. and Contract.*, 37 (1912), No. 17, pp. 476, 477, fig. 1).—Specifications are given for corrugated metal culverts which are put into roads made by using the spoil banks from drainage ditches.

A plan for a small dairy house, E. KELLY and K. E. PARKS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 195, pp. 5, figs. 4).—This contains plans and details for constructing an inexpensive but sanitary dairy house.

The ventilation of stock stables, F. ULRICHS (*Illus. Landw. Ztg.*, 32 (1912), No. 27, pp. 257, 258).—The construction of cow stalls relative to ventilation is discussed, the principal method of ventilation dealt with being that by vapor chimneys.

The development of agricultural machinery in Germany, G. FISCHER ET AL. (*Arb. Deut. Landw. Gesell.*, 1910, No. 177, pp. VIII+436, figs. 325).—This publication deals with the general development of agricultural machinery in Germany, describing and discussing ground-breaking implements, seeders, and cultivators, harvesters, cleaning and sorting machines, feed-preparing machines,

thrashers, hay balers, dairy machinery, farm engines, electricity in agriculture, and pumps.

Wood used in construction of agricultural implements, F. N. G. KRAMCH (*Farm Implements*, 26 (1912), No. 3, pp. 21, 22, 23).—This article deals with the importance of wood in the construction of agricultural machinery, describing the important wooden parts of different implements, and discussing the relative merits of different kinds of woods when used in the construction of parts of various machines.

The hand-winch stump and tree puller (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 1, p. 80).—This machine has a small winding drum about 1 ft. in diameter, worked with an 8-ft. lever pulled by 2 men. A grab disposes of slack rope and a snatch block doubles the direct drum power, making it equal to about 24 tons. The power is transmitted to a flexible wire rope, one end of which is anchored to the butt of a standing tree, and the other looped around the tree to be pulled, about 10 ft. from the ground. In trials recently conducted at the Grafton experiment station, New South Wales, a swamp mahogany tree 2 ft. 9 in. in diameter was pulled out by the roots in 22 minutes.

Motor cultivation on a farm. H. SAGNIER (*Jour. Agr. Prat., n. ser.*, 23 (1912), No. 13, pp. 401, 402).—The operation and cost of operation of an internal combustion motor plow on a farm is discussed.

Examination of a seeding machine for garden or nursery planting, C. FRUWIRTH (*Wiener Landw. Ztg.*, 62 (1912), No. 23, p. 285, fig. 1).—A machine is described which is adapted to planting seeds in gardens, nurseries, or experimental plots. It is so constructed as to plant the seeds in rows at the required depth and distance apart, and is intended as a time- and labor-saving apparatus to be used where especial care in planting is required.

Potato-digging machines, G. SEYMOUR (*Jour. Dept. Agr. Victoria*, 10 (1912), No. 2, pp. 119-122, figs. 4).—The construction and operation of several types of potato-digging machines are described.

A wagon for carrying heavy loads (*Masch. Ztg.*, 10 (1912), No. 7, p. 82, figs. 2).—A wagon is described which is especially adapted to carrying hogs or cattle or other heavy loads. It is so constructed that the bed can be raised or lowered on a steel frame, thus facilitating the processes of loading or unloading.

New ideas in modern straw balers, FABRICIUS (*Masch. Ztg.*, 10 (1912), No. 7, pp. 80-82, figs. 3).—An improved straw baler, some of its accessories, and its operation are described.

## RURAL ECONOMICS.

Agricultural credit and cooperation in England and Wales (*Jour. Bd. Agr. [London]*, 19 (1912), No. 1, pp. 43-50).—Observations are made showing that although agricultural cooperation has not been established to a very large extent in England and Wales, it has in recent years made marked development in the way of cooperative credit, insurance, purchase, production, sales, etc. The state has contributed to the movement by passing legislation making it possible for the societies to be established and registered at small cost, empowering county councils to aid such societies by money grants or guaranties, and providing funds, through the Agricultural Organization Society, for the propagation of cooperative ideas, the encouragement of new societies, and the combination of individual societies into larger cooperative unions.

Attention is called to the most common form of the small holdings and allotment societies, in which a number of intending small-holders form themselves into a society, which in its corporate capacity negotiates for the hire or pur-

chase of land and makes itself the responsible hirer or purchaser of sufficient land to meet the needs of all of its members. The society performs other functions, as the purchase of seed, manures, implements, and other requirements of members, and collects, prepares, and markets their surplus produce. In 1909 there were 146 such societies, with a membership of 7,925.

Cooperative societies (*Rpt. Indus. and Agr. Coop. Soc. United Kingdom, 1912, pp. LV+273, pls. 5*).—An official report presenting notes and statistics relating to industrial and agricultural cooperative societies in the United Kingdom from 1900 to 1910. The agricultural societies are grouped into 3 main classes, viz. purchase and sales societies, productive societies, and small holdings and allotment societies. "Between 1895 and 1909 the agricultural cooperative societies of all kinds making returns increased from 58 (46 for production and 12 for distribution) for the whole of the United Kingdom, to 653 (317 for production and 336 for distribution), while their combined sales increased from £354,379 to £3,609,172."

Agricultural purchase societies in Italy up to 1910 (*Fed. Ital. Consorzi Agr. Piacenza, 2 (1911), pp. XII+505, figs. 149*).—This book presents notes, tables, maps, charts, etc., showing the work done by the Italian Federation of Agricultural Societies from 1892 to 1910 inclusive. It also includes a summary of the information furnished by 420 of the agricultural societies concerning the economic status of the various localities, together with data showing the numerical relations between the purchase societies, the rural population, and the cultivated area, as well as data on the general consumption of commercial fertilizers and the amount provided through cooperative societies.

The importance of the collective purchase societies is partially brought out in the following table:

*Progress of the Italian Federation of Agricultural Societies from 1893 to December 31, 1910.*

Year.	Members.		Capital.	Value of goods delivered to members.	Net profits.	Distribution of net profits.			
	Agricultural societies.	Individuals.				Shareholders.	Purchasers.	Employees.	Reserve fund.
1893....	65	207	<i>Lirc.</i> 12,885	<i>Lirc.</i> 711,147	<i>Lirc.</i> 11,009	<i>Lirc.</i> 665	<i>Lirc.</i> 3,458	<i>Lirc.</i> 864	<i>Lirc.</i> 3,948
1895....	94	264	24,804	810,435	7,463	1,143	2,378	594	2,751
1897....	115	296	38,327	2,118,629	13,109	1,087	4,547	1,136	5,202
1900....	221	348	79,681	2,806,789	1,027	886	35	8	87
1902....	300	377	96,692	3,992,139	19,995	988	7,202	1,800	8,202
1905....	460	472	144,110	9,389,188	23,239	1,154	8,370	2,092	9,531
1908....	565	499	180,159	15,686,158	22,603	2,557	7,566	1,891	8,696
1910....	618	522	216,572	13,448,499	23,147	4,039	7,180	1,795	8,337

The importance of the national insurance law as related to agriculture, SCHUMACHER (*Deut. Landw. Presse, 38 (1911), Nos. 96, pp. 1089, 1090; 97, pp. 1105, 1106; 99, pp. 1130-1132; 100, pp. 1144-1143; 101, pp. 1156, 1157; 102, p. 1168*).—This is a series of articles discussing in detail the national insurance law in Germany in its application to agriculture.

An argument for the short-time lease, E. ELIJAH (*Iowa Agr., 12 (1912), No. 5, pp. 19, 20*).—This article illustrates by concrete examples the economic advantages of short-time as contrasted with long-time leases, pointing out that the short-term lease tends toward friendly relations between landlord and tenant. The landlord can also specify each year just what fields may be plowed up and what ones must be seeded down, thus maintaining the productivity of the soil and insuring a more permanent agriculture.

**Prosperity on a rented farm in Iowa**, R. NICHOLSON (*World's Work*, 23 (1912), No. 6, p. 718).—This article presents the experience of a landowner in Iowa who sold his 320-acre farm in 1908 at \$90 per acre, and leased back 240 acres of it for 5 years. The results were very satisfactory. The net profit, in addition to the interest on the money received for the sale of land, in 1910 was \$1,677.60 and promised to be larger in 1911.

**Profitableness of agriculture in Argentina**, PFANNENSCHMIDT (*Ztschr. Agrarpolitik*, 10 (1912), No. 4, pp. 126-143).—This article presents notes and statistics showing the cost of each factor entering into the production of wheat, flax, oats, and other crops on different kinds of land in Argentina, especially the relative value of efficient labor.

The cost of breaking and preparing new land and seeding it to wheat with the more efficient labor and paying for insurance against hail is estimated at 17.6 pesos per hectare (about \$6.83 per acre), and with less efficient labor 26.75 pesos. On old land the cost with the more efficient labor is 10.3 pesos per hectare and with less efficient labor 17.85 pesos. The cost of harvesting on both old and new land with the more efficient labor is 9.75 pesos per hectare, and with the less efficient labor 15.25 pesos. The total cost per hectare on new land that will produce 5 quintals per hectare is 38.35 pesos with the more efficient labor, and on old land 31.05 pesos; on new land with less efficient labor 53 pesos, and on old land 41.1 pesos.

Corresponding data are given for other crops and wheat on other grades of land. A bibliography is also included.

**High cost of living and agriculture in France**, M. LAIR (*Rev. Econ. Internat.*, 9 (1912), I, No. 3, pp. 496-525).—This article presents the results of a rather comprehensive research, in which it discusses and illustrates under the following headings a number of causes affecting the cost of living and its relation to agriculture in France: The French market; recent rise of the chief products; identical movement of the custom duties; French agriculture as a national industry; progress of the production; tendency of France to provide for itself; decrease of the agricultural population and scarcity of workmen; difficulties in the use of mechanical and industrial processes; effect of social and fiscal laws on the increasing prices; influence of speculation; and administrative influences.

**Agriculture in Egypt**, B. O. COWAN (*Breeder's Gaz.*, 61 (1912), No. 17, pp. 988, 989).—This is a popular article describing at length the agricultural possibilities of Egypt, together with its drawbacks, due to the ancient agricultural methods still practiced by the Egyptian farmers.

[Agricultural] production (*So. Aust. Statis. Recg.*, 1910, pt. 3, pp. 1-148).—This is a statistical register showing the area and distribution of holdings in South Australia in 1910 to be as follows: Total area, 105,686,504 acres: occupied by owners, 7,266,867 acres; occupied by tenants, 874,119 acres; lands held under agreement to purchase from the crown, 2,461,412 acres; crown lands leased, 95,084,106 acres: total area under crops, 2,746,334 acres; under permanent artificially sown grasses, 26,416 acres; previously cropped land lying idle during the season, 2,192,478 acres; new ground cleared during the season, 369,150 acres; land in fallow, 1,369,242 acres; and balance of the holdings, 98,982,524 acres. Persons employed or who regularly assist in farm work are classified as follows: General farming, 34,251 males and 5,398 females; dairying, 1,602 males and 10,186 females; and pastoral, 5,166 males and 891 females.

Other statistics are given showing the area under each crop, the produce thereof for a period of years and the average market price, the number, description, and value of live stock, live stock products, etc.

Agricultural statistics (*Statist. Abs. Prin. and Other For. Countries [Gt. Brit.], 37 (1899-1910), pp. 310-331*).—A statistical abstract showing the acreage under crops, yields, number of live stock, etc., in each year from 1899 to 1910 in the following countries: Russia, Norway, Sweden, Denmark, Germany, Netherlands, Belgium, France, Spain, Italy, Austria, Hungary, Bulgaria, Roumania, Algeria, Argentina, Uruguay, Japan, Great Britain, and the United States.

Foreign crops, March, 1912, C. M. DAUGHERTY (*U. S. Dept. Agr., Bur. Statist. Circ. 30, pp. 12*).—Notes and statistics showing area, production, exports, and price of the principal agricultural crops and livestock in Argentina for a number of years are here presented. Wheat being the principal crop, it is of interest to note that the area has increased from 2,970,656 acres in 1890-91 to 17,027,545 acres in 1911-12, and the yield from 31,048,117 bu. to 170,562,553 bu. The other leading crops are alfalfa, corn, and flaxseed, Argentina being the principal producer of flaxseed.

### AGRICULTURAL EDUCATION.

Education for agriculture, F. B. MUMFORD (*Ann. Amer. Acad. Polit. and Soc. Sci., 40 (1912), No. 129, pp. 19, 20*).—This article emphasizes the importance of those types of education which demonstrate their efficiency in training men and women for the social, economic, and political duties of the rural communities and the State at large. It further notes that the opportunity for giving such training in schools teaching agriculture is demonstrated by the increasing demand for farm managers, teachers, investigators, various agricultural experts, and other men and women who are to be in a position to make large contributions toward the solution of these problems.

The country school, H. W. FOGHT (*Ann. Amer. Acad. Polit. and Soc. Sci., 40 (1912), No. 129, pp. 149-157*).—In discussing the vitalizing influence of the ideal country school as a factor entering into the socialization of the new rural life, and as the form of education which is to reflect the daily life and interests of the rural community, the author points out that such a school must give expression to at least two things: (1) Good scientific farming, rendering ample returns for the labor expended, and (2) a rural social life satisfactory to those living in it. It must further require at least three things of the teacher: (1) He must be strong enough to establish himself as a leader in the community where he lives and labors; (2) he must have a good grasp on the organization and management of the new kind of farm schools; and (3) he must show expert ability in dealing with the redirected school curriculum.

Referring to the charges frequently made against the rural school, that it has drawn too much of its substance from sources foreign to rural needs, and that it has failed in other ways to keep pace with the demands of our rapidly developing agricultural life, the author suggests that, in order to check this tendency and so redirect the work that the rural school may become rooted to the soil in such a way as to become the chief agency in the social and economic reconstruction of rural life, there be: (1) A thorough redirection of the subject matter taught in the schools; (2) a general reorganization of the entire working staff of administrators, supervisors, and instructors; and (3) the rebuilding in many instances of the entire school plant.

Rules, regulations, and laws relating to high and graded schools (*Min. [Dept. Pub. Instr.] Bul. 35, 1912, pp. 50+3*).—This bulletin includes, among others, rules of the department applying to high and graded schools maintaining departments of agriculture and home economics or manual training, laws relating to the teaching of agricultural and industrial work, required equipment, etc.

**Teachers' extension schools.** G. A. BRICKER (*School Rev.*, 29 (1912), No. 4, pp. 266-279).—The author points out that federal funds derived from the Nelson Amendment are available in each State for conducting teachers' extension schools in agricultural education through the initiative of the land-grant colleges, and gives an account of the organization and management of 3 such which were established in Ohio, at Circleville on October 28, 1911, and at Mt. Vernon and Van Wert on January 13 and 20, 1912, according to a plan which he is working out experimentally under the auspices of the College of Education of the Ohio State University.

**The Scottish system of continuation schools.** E. G. COOLEY (*Vocational Ed.*, 1 (1912), No. 4, pp. 225-242).—In this article the author gives an account of the system of continuation schools in Scotland, including the plan of continuation schools in Edinburgh. In this there are (1) classes for the completion of general elementary education, including instruction in needlework, cookery, laundering, dressmaking, and millinery; (2) classes for elementary instruction in special subjects, among which are horticulture and any industry the scientific principles underlying which admit of systematic exposition, and handwork including cookery, laundering, and dairy work; and (3) organized courses of systematic instruction to fit students for the practice of particular crafts, industries, or occupations approved by the department of education, among which courses is one in agriculture and rural industries.

**The "Landwirtschaftliche Institut" of the University of Halle, Germany.** H. C. PRICE (*Agr. Student*, 18 (1912), No. 8, pp. 461-466, figs. 2).—A brief account is given of the organization and equipment of the agricultural institute of the University of Halle, which is especially notable because it was the first institute of its kind established in a university (in 1862), and also because it has the largest number of students (366 last year and 381 this year) of any of the agricultural institutes of the German universities. The subject of agriculture is divided into 3 main divisions, (1) agronomy, (2) animal husbandry and dairying, and (3) farm management. All other subjects are made secondary or given as independent courses by special lecturers as in the case of horticulture. This is given by the director of the Province Fruit Experiment Station, which is entirely separate from the university but located near Halle. The work consists principally of lectures. Class rolls and examinations are entirely lacking except that a student must be examined when he wants a teacher's certificate, a diploma, or a doctor's degree.

**Reports on agricultural and housekeeping schools for 1910-11** (*Aarsber. Offentl. Foranst. Landbr. Fremme*, 1911, II, pp. 280).—Brief accounts are given of the agricultural schools and housekeeping schools in Norway.

**Agricultural nature study.** C. F. PALMER (*Addresses and Proc. Nat. Ed. Assoc.*, 49 (1911), pp. 1118-1126).—An address before the National Education Association, San Francisco, Cal., July 8-14, 1911, in which the author discusses the importance of instruction in agricultural nature study and outlines the general scope of such work, showing particular phases of the work best adapted to different school grades. The greatest drawback is pointed out as the lack of properly trained teachers and the lack of understanding of the mutual relationship between the biological and physical sciences. He notes how this difficulty is being overcome in many places by special and summer courses on the subject in normal schools and agricultural colleges.

**First annual report of the School Garden Association of America** (*Ann. Rpt. School Garden Assoc. America*, 1 (1912), pp. 32, figs. 12).—This includes reports of the officers and proceedings and other data.

**Kentucky Arbor and Bird Day, 1911.** ETHEL REID (*Frankfort, Ky.: Dept. Ed.*, 1911, pp. 140, pls. 10, figs. 18).—This compilation consists of a history of

Arbor Day and Bird Day, suggestions for teachers and pupils, programs, and lessons, poems, and music on trees, flowers, and birds.

**Report of committee on courses of study in agriculture, E. C. BISHOP** (*Addresses and Proc. Nat. Ed. Assoc.*, 49 (1911), pp. 1138-1152).—This report, submitted to the National Education Association, San Francisco, Cal., July 8-14, 1911, makes general inquiries into the scope of agricultural education and its relation to present-day principles in education, and presents suggestions as to specific courses in agriculture, the governing influences in the arrangement of such courses, and the pedagogical procedure in organizing the subject in schools maintaining the usual general public school courses of study. In addition to an outline of the work as pursued in a few of the States, a summary of successful practices in teaching agriculture in the rural school with one teacher is presented.

**Spring laboratory methods, S. A. MINEAR** (*Bul. Okla. Agr. and Mech. Col.*, 8 (1912), No. 26, pp. 8, figs. 9).—Laboratory exercises (1) to increase the production of corn by judicious selection of seed ears, (2) the determination of good cotton seed for planting purposes, (3) a practical study of the yield of oats, (4) to demonstrate how plants feed, (5) the amount of moisture, and (6) the loss of moisture after rains, are outlined by the author.

**Potato studies for schools, J. W. HUNGATE** (*Dept. Agr. State Normal School [Cheney, Wash.]*, *Bul. A*, No. 2, 1912, pp. 15, figs. 5).—This pamphlet gives instructions as to planting, cultivating, and harvesting the potato crop, including exercises on the structure, albumin, and water content of the potato, its use for seed planting operations, treatment for scab, seed selection, storing, and scoring potatoes.

### MISCELLANEOUS.

**Annual Reports of the Department of Agriculture, 1911** (*U. S. Dept. Agr. Rpts. 1911*, pp. 1010).—This consists of the report of the Secretary and heads of Bureaus. The various reports are also issued as separates. A portion of the report of the Secretary, comprising a discussion of the economic results of cold storage, is abstracted on page 164 of this issue.

**Twenty-seventh Annual Report of the Bureau of Animal Industry, 1910** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1910*, pp. 573, pls. 42, figs. 75).—This contains a report of the Chief of the Bureau for the fiscal year ended June 30, 1910, numerous articles abstracted elsewhere in this issue, and a list of the publications of the Bureau during 1910. An appendix contains the rules and regulations of the Secretary of Agriculture relating to animal industry issued during 1910.

**Annual Report of Hawaii Station, 1911** (*Hawaii Sta. Rpt. 1911*, pp. 63, pls. 7, figs. 6).—This contains the organization list, a summary by the special agent in charge as to the investigations of the year, and reports by the entomologist, horticulturist, chemist, and agronomist. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Twenty-fourth Annual Report of Michigan Station, 1911** (*Michigan Sta. Rpt. 1911*, pp. 147-510, pls. 2, figs. 51).—This contains reports of the director and heads of departments on the work of the station during the year, the experimental features of which are abstracted elsewhere in this issue, reprints of Bulletins 262 to 264, Special Bulletin 54, Technical Bulletins 5 to 10, and Circulars 10 and 11, previously noted, and a financial statement for the fiscal year ended June 30, 1911.

## NOTES.

---

**California University and Station.**—Dean T. F. Hunt, of the Pennsylvania College and Station, has been appointed to succeed Dean Wickson as dean and director. Recent appointments as instructors include James Koeber in farm mechanics, William H. Arnold in chemistry and botany, W. F. Gericke and Paul S. Burgess in soils, and Ralph H. Taylor in horticulture. W. B. Herms has been promoted to the assistant professorship of applied parasitology, and W. G. Hummel to the assistant professorship of agricultural education.

An additional substation was opened May 25 at Meloland in Imperial County, where a tract of about 40 acres has been secured and buildings and water supply provided. Attention is to be given to demonstration work with fruits, grains, forage plants, cotton, and other crops. Walter H. Packard will be in charge of the substation.

**Iowa College and Station.**—W. J. Kennedy, former head of the animal husbandry department, has been appointed superintendent of agricultural extension, vice P. G. Holden, resigned, and will be succeeded by W. H. Pew. A. V. Storm, head of the department of agricultural education, has resigned to accept a similar position at the University of Minnesota. Nelson C. Brown, assistant professor of forestry, has resigned to become assistant professor of forest utilization in the New York State School of Forestry at Syracuse University.

Other resignations include M. L. King, experimentalist in agricultural engineering, and in the extension division A. H. Snyder, Murl McDonald, G. R. Bliss, and A. A. Burger. Robert Snyder and E. H. Kellogg have been appointed assistants in soils in connection with the position made vacant by the resignation of A. A. Wells.

A school of silo construction was held at the college June 3 to 7, with an attendance of about 60.

**Kansas College and Station.**—W. A. Coehel, of the Pennsylvania College and Station, has accepted the position of animal husbandman, beginning July 1.

**Louisiana Stations.**—The general assembly appropriated \$50,000 at its recent session for the support of the agricultural schools of the State, an increase of \$25,000 over last year. An appropriation of \$3,000 for the repair of the sugar house at the Audubon Park Station was also granted.

A tract of 60 acres has been purchased for the use of the station at Baton Rouge adjacent to its present holdings.

The agricultural demonstration train has completed a trip of 4,625 miles over 15 different railroads, attracting an estimated attendance of 142,885.

E. J. Watson, horticulturist at the Calhoun Station, has resigned to take effect August 1.

**Massachusetts College and Station.**—An offer of \$150 yearly for three years has been made by F. Lothrop Ames for prizes to the three men doing the best work in live stock judging. The fund will be utilized in defraying the expenses of competition in the live stock judging contests at the National Dairy Show.

Frank F. Moon, associate professor of forestry, has resigned to become professor of forest engineering at the New York State College of Forestry at Syracuse University. Dr. Ernest Anderson, research instructor in chemistry at the University of Chicago, has been appointed assistant professor of general and physical chemistry.

In the station, Director W. P. Brooks has been granted leave of absence, and Vice Director J. B. Lindsey is temporarily in charge. Herbert J. Baker, secretary to the director, resigned July 1. C. L. Beals and Howard A. Turner, 1912 graduates of the college, received appointments July 1, the former as assistant chemist in the fertilizer section, and the latter as graduate assistant in horticulture.

**Minnesota University and Station.**—A new building, 168 by 169 feet, is under construction for the department of agricultural engineering, and it is hoped to complete at least the portion devoted to shop work early in 1913. A girls' dormitory, costing \$50,000, has recently been completed at Morris, and a similar dormitory for boys is to be begun in the near future. A science building, costing \$40,000, is nearing completion at Crookston.

W. A. McKerrow has been appointed specialist in animal husbandry in the extension division, with the rank of assistant professor, to succeed W. H. Tomhave, who has accepted the position of animal husbandman at the Pennsylvania College and Station.

**Mississippi College and Station.**—G. R. Hightower succeeded J. C. Hardy as president of the college July 1. R. L. Shields has resigned as professor of animal husbandry to become professor of animal husbandry and dairying at Clemson College and Station, and was succeeded by Archibald Smith September 1. Other appointments include J. K. Morrison as college and station poultryman, Dr. C. F. Briscoe as station bacteriologist, and Dr. J. C. Robert as dean of the school of agriculture and professor of agronomy.

**Nebraska University and Station.**—O. L. Sponsler, in charge of the forestry work, has resigned to accept the position of junior professor of silviculture in the University of Michigan. R. F. Howard, assistant professor of horticulture and assistant horticulturist, has resigned to accept a similar position in the University of Wisconsin, beginning September 1.

**New Hampshire College and Station.**—T. R. Arkell, associate professor of animal husbandry and animal husbandman, has resigned to accept a position with the Canadian Department of Agriculture as head of the sheep division. He will investigate for the present sheep breeding and the wool industry in Manitoba, Saskatchewan, and Alberta.

**Cornell University.**—The recent appropriations of the legislature authorize the construction of a \$100,000 forestry wing of the proposed plant industry building, a \$91,000 animal husbandry laboratory building, a \$38,000 live stock judging pavilion, and a \$100,000 extension to the agronomy wing of the present main building. In addition, \$265,000 was granted for current expenses of the college of agriculture, \$50,000 for extension work, \$30,000 for equipping the home economics building, \$15,000 for equipping the poultry husbandry building, \$4,000 for the summer school, \$20,000 for additional instruction in physics and chemistry, \$20,000 for various additions, grading and improvement of grounds, and \$2,000 for investigations of the diseases of the gladioli and other bulbous plants. Excavations are under way for the new agricultural auditorium building, which will be perhaps the most imposing building of the university and will serve as a connecting architectural link between the agricultural group and the main campus. It will be one of the largest auditoriums in western New York, seating over 2,500 people, besides affording additional facilities for class rooms and laboratories. The contract calls for its completion November 1.

Samuel N. Spring, state forester of Connecticut, has been appointed professor of forestry. Other appointments include the following: As instructors, M. J. Prucha and G. R. Hill, jr., in plant physiology, Charles Gregory and C. P. Smith in plant pathology, H. O. Buckman in soil technology, C. E. Ladd in farm management, H. M. Pickrill and T. J. McInerney in dairy industry, Clara Brown in home economics, E. M. Tuttle in rural education, and Royal Gilkey in extension teaching; and as assistants, J. T. Francis, Charles Chubb, and L. M. Massey in plant pathology, T. E. Schreiner in poultry husbandry, and E. D. Montillon in rural art.

**North Carolina College Station.**—Guy W. Wilson has resigned as assistant in plant diseases to take up graduate work at Columbia University.

**Ohio State University.**—A course in plant genetics is to be offered for the first time next year. F. R. Marshall has accepted a position as head of the animal husbandry department of the California University and Station.

**Pennsylvania Institute of Animal Nutrition.**—Director H. P. Armsby has been elected a foreign member of the Royal Academy of Agriculture of Sweden.

**Rhode Island College and Station.**—Philip H. Wessels, who was formerly assistant chemist and who has been a graduate student at the University of Wisconsin, has returned as first assistant chemist to the station. Leroy F. Whipple has resigned as assistant chemist to engage in commercial work. Frank O. Fitts, a 1912 graduate of the Massachusetts College, has been appointed assistant chemist, and George E. Merkle, also a graduate of the Massachusetts College, has been appointed assistant in agronomy and chemistry in the college and station.

**Clemson College and Station.**—W. L. Hutchinson, formerly director of the Mississippi Station, has been appointed to the professorship of agronomy. Recent resignations include those of J. M. Napier as assistant professor of agronomy to engage in farming; W. P. Gee as assistant professor of entomology to take up graduate work at the University of California; C. C. Vincent as associate professor of horticulture to accept a position with the University of Idaho; L. A. Niven as assistant in horticulture in the extension division to engage in horticultural journalism; and Dr. W. F. Burleigh as assistant veterinarian to engage in veterinary practice.

R. W. Simpson, a life member of the board of trustees and for over twenty years its president, died July 11 at the age of 72 years. As executor of the will of the late Thomas G. Clemson, which provided a considerable bequest for an agricultural and mechanical college in South Carolina, he was prominently identified with the establishment of the present institution.

**West Virginia University and Station.**—O. M. Johnson, of Ohio State University, has been appointed associate professor of farm management and in charge of farm management in the station, in cooperation with the Farm Management Investigations of this Department. P. B. Bennetch, of the State School of Agriculture at Canton, N. Y., has been appointed assistant professor of dairying in the university and dairyman in the station. L. M. Peairs, of the Kansas College and Station, has been appointed associate professor of entomology and entomologist, vice F. E. Brooks, resigned. K. H. Knudsen, assistant chemist, has resigned to engage in commercial work in Norway. In the department of horticulture, A. L. Dacy has been appointed associate professor of horticulture, E. C. Auchter and L. F. Sutton assistants, and A. B. Brooks, a 1912 graduate of the university, instructor in the university and assistant in the station.

The first state country life conference had a successful session July 15 to 18.

**Office of Experiment Stations.**—S. H. McCrory, connected with the field work of the Drainage Investigations of this Office since 1907, has been appointed engineer in charge of drainage work, and has entered upon his duties. J. O.

Rankin, who has been associated with the field crops section of *Experiment Station Record*, has resigned to become editor for the Minnesota University and Station.

**Seaman A. Knapp School of Country Life.**—A grant of \$250,000 by the General Education Board has been announced to the George Peabody College for Teachers, at Nashville, Tenn. This fund is to be utilized for the establishment of the Seaman A. Knapp School of Country Life, which will give special attention to the training of teachers for rural schools, and in accordance with the usual policy of the board is contingent upon the raising of an equal sum by the institution.

**Royal International Horticultural Exhibition.**—This exhibition, held in the grounds of the Royal Hospital, Chelsea, England, comprised numerous scientific exhibits from various institutions and two conferences, one on May 23 on horticultural education, and the other on May 24 on legislation in connection with insect pests. Papers were contributed to the educational conference by Dean Bailey, of Cornell University, on Horticultural Education in America; K. Weinhausen, of Berlin, on Horticultural Education in Germany; Prof. A. Buysens, of the School of Horticulture at Vilvorde, on Horticultural Education in Belgium; and W. Hales on the Education of a Gardener. The value of importation regulations as a means of preventing the introduction of plant pests was discussed by Prof. L. Ritzema Bos, of Holland. A. G. L. Rogers considered the aim of legislation in Great Britain, and A. W. Sutton discussed import dues and regulations. Legislation in connection with insect pests was discussed by H. Maxwell-Lefroy, of India, and that for fungus diseases by H. T. Güssow, botanist for the Canadian Department of Agriculture.

Hon. Walter Runciman, president of the Board of Agriculture and Fisheries, gave an address in which he announced the establishment of a new division of the board for exclusive attention to horticultural interests. A. G. L. Rogers has been appointed head of the division, and is to be assisted by an entomological expert, eight other experts, and a clerical staff.

**Prospective Agricultural Meetings.**—Announcement is made of the seventh International Dry Farming Congress, which will meet at Lethbridge, Alberta, October 21 to 26. The twentieth annual Irrigation Congress will be held at Salt Lake City, Utah, September 30 to October 8. The American Breeders' Association will meet at Columbia, S. C., January 24 to 27, 1913, in connection with the fifth National Corn Exposition.

**Miscellaneous.**—The Franklin Institute of Philadelphia has awarded to Dr. Oswald Schreiner and Elbert C. Lathrop, of the Bureau of Soils of this Department, the Edward Longstreth medal of merit for a paper entitled *The Distribution of Organic Constituents in Soils*, which appeared in the August, 1911, issue of the *Journal of the Franklin Institute*.

Dr. E. J. Russell has been appointed director of the Rothamsted Station, in succession to A. D. Hall, whose resignation has been previously noted.

William R. Smith, for sixty years superintendent of the National Botanic Gardens, died at Washington, D. C., July 7, at the age of 84 years.

The death is noted of Dr. Ernst Schulze, professor of agricultural chemistry at the Zurich Technological Institute, at the age of 72 years.

## CONTENTS OF VOL XXVII, NO. 3.

	Page.
Recent work in agricultural science.....	201
Notes.....	300

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Metabolic water: Its production and rôle in vital phenomena, Babcock.....	201
Contribution to our knowledge of plant phosphatids, Njegovan.....	202
The localization of betain in plants, Staněk.....	203
The betains occurring in plants, II, Schulze and Trier.....	203
The occurrence of betains in the plant kingdom, Yoshimura and Trier.....	204
Micro-organisms and fermentation, Jörgensen.....	204
Silage fermentation, Esten and Mason.....	204
Agricultural chemistry, Otto.....	205
Chemical-technical methods of analysis, edited by Lunge and Berl.....	205
Theory and practice of volumetric analysis, Classen.....	205
The neutral permanganate method for availability of organic nitrogen, Street..	205
Activity of organic nitrogen and the alkaline permanganate method, Jones....	206
A method for determining phosphoric anhydrid colorimetrically, Passerini...	206
A rapid volumetric method for estimation of free sulphur, Davis and Foucar..	206
Detection of fluorids, Rupp.....	206
Work on the composition, analysis, and adulteration of foods, Vandevelde.....	206
Compendium for food chemists, Bujard and Baier.....	207
Netherland food codex, Vandevelde.....	207
The valuation of edible fats by color reactions, Serger.....	207
Examination of diseased potatoes with Reimann's potato balance, Hals.....	207
An electrical conductivity test for purity of maple sirup, Snell.....	207

	Page.
Official methods for the examination of chocolate and cocoa	207
Detection of caramel in fermented beverages, Pasquero and Cappa	207
Analysis of candied lemon peel, Härtel and Kirchner	208
Technical drug studies by the division of drugs	208
Biochemistry of colostrum, Engel	208
Investigations in regard to the hemolytic power of cow's colostrum, Köbele	208
Note on the gravimetric estimation of phosphorus in milk, Miller	208
Comparison of methods of sampling cream for testing, Lee and Hepburn	208
The aldehyde figure of butter, Miller	209
Procedure for determining the sugar content of bagasse, Hazewinkel et al.	210
The changes which take place in sugar beets during storage, Friedl	210
Comparative influence of water and virasse upon the pulp residues, Ammann	210
The desiccation of potatoes and the uses of the product, Moore	210
Forest chemistry, 1909-10, Singh	210

## METEOROLOGY—WATER.

The climate of Ohio, Smith	211
Meteorological observations at Massachusetts Station, Ostrander and Hallowell	211
The weather of 1911 at the Midland Agricultural and Dairy College, Wakerley	211
Report of the station of agricultural climatology of Juvisy, 1910, Flammarion	211
Weather forecasts for 1912 in Russia, Savizkii	212
Our weather, Fowler and Marriott	212
Smoke.—A study of town air, Cohen and Ruston	212
Combined nitrogen in rain, Gimmingham	212
Ponds in agricultural districts, Martin	212
Sewage disposal, Fuller	212
Practical methods of sewage disposal, Ogden and Cleveland	213

## SOILS—FERTILIZERS.

Present problems in soil physics as related to plant activities, Livingston	214
The temperature of the soil under different conditions, Dunlop	214
Studies of the heat conductivity of some soil types, Karsten	215
Suspensions and the phenomena of absorption, Arrhenius	215
The plant and the salts of the soil, Tukaikov	215
The biological absorption of phosphoric acid in the soil, Dushechkin	216
The origin of loess, Henning	216
Soil fertility, Hopkins	216
Cooperative study of Rhode Island soil deficiencies, Wheeler et al.	216
Soil mapping and soil analyses, Hissink	216
Investigations on pine-covered sand dune soils, Vogel	217
Studies of the tillable soils of Roumania, Murgoci	217
The composition of sandy soils of Tripoli, Menozzi	217
Some cotton soils of the Nyasaland and Uganda protectorates	217
The pinery and orchard soils of the Bathurst Division, Cape Province, Lewis	217
[Analyses and determinations of moisture of Queensland soils], Brännich	217
Fertilizers and crops, Van Slyke	218
Commercial fertilizers and agriculture of the Alps, Kerler	218
Calcium cyanamid as compared with nitrogenous fertilizers, Da Silva	218
The constitution of basic slag, Hartleb	218
The influence of lime on cultivated soil	218
The trade in cotton-seed meal, Jenkins	219
Experiments with gas purification residue, von Feilitzen	219
Tannery refuse as a fertilizer, Healy	219
Refuse disposal, Toronto, Ont.	219
Analyses of fertilizers, fall season, 1911, Kilgore et al.	219
Tabulated analyses of commercial fertilizers, Tomlinson	219
Analyses of licensed commercial fertilizers, 1912, Woll	219

## AGRICULTURAL BOTANY.

Plant physiology, Palladin	219
New findings in germination studies with <i>Chloris ciliata</i> , Gassner	219
Temperature and seed germination, Lehmann	220
The effect of heat on seeds in a state of anesthesia, Apsit and Gain	220

	Page.
The so-called respiration of powdered seeds, Iwanoff.....	220
Effect of warm baths on resting plants, Iraklfonov.....	220
Shortening resting period of shoots by wounding and injection of water, Weber.....	221
The influence of enzymes on the respiration of plants, L'vov.....	221
The light requirement of plants in relation to leaf form and position, Wiesner.....	221
The relation of light and temperature to leaf fall, Varga.....	221
Studies on cessation of flowering, Wacker.....	221
Opening and closure of stomata as shown by method of infiltration, Molisch.....	221
A new method of estimating the aperture of stomata, Darwin and Pertz.....	222
Transpiration in wet leaves, Hlin.....	222
Transpiration and the ascent of sap, Dixon.....	222
Measuring the transpiration of emersed water plants, Otis.....	223
The relative wilting coefficients for different plants, Briggs and Shantz.....	223
Conditions which affect the branching of roots, Newlon.....	223
Agricultural microbiology, Kayser.....	223
Soil fungi, Goddard.....	223
The occurrence of <i>Zygorhynchus molleri</i> in Michigan, Grossman.....	223
Formation of volatile acids after fermentation, Osterwaller.....	223
A new fermenting fungus, Osterwaller.....	224
The mycorrhiza of <i>Solanum</i> , Bernard.....	224
<i>Gastrodia clata</i> and its symbiotic association with <i>Armillaria mellea</i> , Kusano.....	224
The fungicidal action of bulbs of orchids, Bernard.....	224
Effects of Roentgen rays on micro-organisms and ferments, Günther.....	225
Nitrogen-fixing bacteria in leaves of Rubiaceae, von Faber.....	225
Nitrogen fixation by fungi in relation to nitrogen nourishment, Stabel.....	225
Nitrogen assimilation and a new hypothesis of protein formation, Baudisch.....	226
Protein synthesis in lower plants, Puriewitsch.....	226
A physiological study of nitrate-reducing bacteria, Fred.....	226
Potash requirement by the nitrogen bacteria, Vogel.....	226
Ammonia and nitrates as a nitrogen source for mold fungi, Ritter.....	226
Anaerobic decomposition of protein and intramolecular respiration, Godlewski.....	226
The nutrition of some epiphytic Bromeliaceae, Picado.....	227

## RECENT WORK IN AGRICULTURAL SCIENCE.

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Metabolic water: Its production and rôle in vital phenomena.** S. M. BABCOCK (*Wisconsin Sta. Research Bul. 22, pp. 87-181*).—The author believes that sufficient distinction has not been made in plant and animal physiology between the function of water which is imbibed and that which is produced as a result of metabolism—oxidation, dehydration of carbohydrates, etc. The metabolic production of water is always associated with the absorption of free oxygen and an evolution of carbon dioxide, the latter being practically in the same ratio as the absorbed oxygen. The water so produced is in many instances essential to the life of the organism.

The results of some experiments with seeds (*Zea mays*), made for the purpose of determining the influence of drying upon germination, show that seeds which were dried for a considerable length of time lost in germinating power and showed weak sprout production, while those dried and immersed in hydrogen peroxid did not germinate at all.

The rate of respiration is within certain limits governed by the amount and distribution of water contained in the seed. The presence of carbon dioxide was found to retard germination somewhat, the retardation being proportional to the amount of oxygen present. Corn stored in an atmosphere of carbon dioxide in a sealed flask, for a period of 30 days, gave evidences of intra-molecular respiration (or anaerobic fermentation), and showed an increase of water from 29.66 to 33.94 per cent. None of this corn germinated when tested later.

Corn treated with solutions of glucose (3 per cent) showed a much higher percentage of germination than that treated with water alone. The embryo of seeds (corn) was found to absorb water more rapidly than the endosperm.

Germination tests conducted with hydrogen peroxid, in strengths from  $\frac{1}{2}$  to 3 per cent, showed " that a very satisfactory method of making germination tests is to place the seeds between filter papers that are afterwards moistened with a  $1\frac{1}{2}$  per cent solution of hydrogen peroxid. In this way a large excess of the reagent is avoided and growth of parasitic organisms prevented. It is well in this case to renew the solution after 24 hours, the surplus liquid being poured off or absorbed by dry filter paper. In general, small seeds such as tobacco, timothy, clover, etc., have not germinated as readily with hydrogen peroxid as when water only was employed. Good results have been obtained with corn, wheat, rye, barley, buckwheat, peas, and beans either when immersed in the reagent or when placed between filter papers and moistened with it. Oats have not germinated well, by either method, unless the hulls were previously removed; when this was done oats germinated as well in hydrogen peroxid as

hydrogen peroxid than in water. This suggests that the method may serve the by a low percentage of germination, requires a longer time for germination in hydrogen peroxid than in water. This suggests that the method may serve the purpose of discriminating between doubtful and good seed."

The water content of sprouts, roots, and stems after separation from the embryo, 48 hours after germination, was found to range from 84.8 to 90.17 per cent (average 87.75 per cent). The moisture content of soaked grain was less than that of germinated grain, the most striking increase taking place in the embryo. The percentage increase in the germinated grain can not be all attributed to imbibed water, and in all probability is due to the production of metabolic water. In the case of mature plants, wilting is in part produced by the abstraction of water from the leaves, which is needed for the hydrolytic processes which are going on in the plant during sunshine.

Tubers and bulbs when stimulated to sprouting produce moisture as a result of dehydration and oxidation processes, to an amount much greater than was originally present in the tuber or bulb. The most water is present in the sprout. A similar process occurs in fruits. Immature seeds when exposed to the air for a time can be made to germinate. The lack of germinating power in the original seed as picked is due to the fact that certain necessary specific enzymes are not present. The theory of Naegeli in regard to the nature of imbibition in plants is criticised. "It seems far simpler to account for the phenomena of imbibition by a direct molecular combination of the substances composing the tissues of organized bodies and water, than by assuming the existence of micelle, the structure and form of which can not be demonstrated."

Seeds when immersed in water generate a certain amount of heat which is due to the union of the starch with water. When sprouting begins it is due to the oxidation of sugar. "The final ripening changes in most fruits proceed fully as rapidly after removal from the tree as when left undisturbed. These changes are the result of direct respiration of living cells in the fruit which continue to function after the fruit is picked. The increase in succulence during ripening is partly due to the production of metabolic water through respiration and partly to the increased solubility of the products formed. It is not due to water derived from the parent plant. The water content is proportionately greater in ripe fruit than in green fruit, in spite of considerable loss of water through evaporation, even though the fruit be ripened off the tree."

With many animals the most of the water required in their metabolism is derived from the oxidation of organic nutrients. "Many varieties of insects and other animals that excrete the waste products of protein metabolism as salts of uric acid in solid form require no free water at any time, except the small amount present in air-dried food, the water content of which is usually less than 10 per cent. This is possible because the insoluble nature of uric acid renders it but slightly poisonous and permits of its excretion with a minimum loss of water. This is the case with the clothes moths, the grain weevils, the bee moth, and a large number of insects that live upon air-dried food throughout every stage of their development. The larvae of these insects contain from 5 to 10 times the amount of free water contained in their food. Some of these insects are capable of living long periods upon dry food in an atmosphere containing no moisture. No doubt they would live indefinitely upon dry food if this could be supplied without exposure to dry air which enormously increases the loss of water by evaporation."

**Contribution to our knowledge of plant phosphatids, V. NJEGOVAN** (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1911), No. 1, pp. 1-26; *abs in Zentbl. Physiol.*, 25 (1911), No. 26, pp. 1222, 1223; *Zentbl. Expl. Med.*, 1 (1912), No. 2, p.

58).—By extracting the seeds of *Lupinus albus* a phosphate complex was obtained which consisted of a portion easily soluble in alcohol and a portion difficultly soluble. The latter has been previously investigated by Winterstein and Stegman (E. S. R., 23, p. 7).

Fractionations made with alcohol, ether, and acetone of the portion easily soluble in alcohol yielded 12 different fractions, of which 3 could be considered true phosphatids. The rest were more or less pure, but could not be considered definite carbohydrates, and in all probability were mixtures or compounds of carbohydrates and nitrogen-containing substances. The fractions soluble in acetone were found to contain phosphatids, odoriferous substances, lipochrome, and possibly stearin and fats.

The 3 phosphatids contained 3.16, 4.31, and 3.33 per cent of phosphorus, and 1.38, 1.56, and 1.46 per cent of nitrogen, respectively. The cleavage products contained stearin, palmitin, and unsaturated fatty acids, and 2 contained glycerophosphoric acid. One of the preparations also contained an organic base which was not studied; another cholin; and another contained instead of cholin a base having the composition  $C_6H_{12}N_2O_2$  and named "Vidin."

The localization of betain in plants, V. STANĚK (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 72 (1911), No. 5-6, pp. 402-409; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 587, II, pp. 818, 819).—Analyses were made of various parts of *Beta vulgaris saccharum*, *Triticum vulgare*, *Lycium barbarum*, *Atriplex canescens*, and *Amaranthus retrofractus*, by a method which is described. It was found that betains are very irregularly located in the plant. A large amount of betain is present in the leaves during the early stage of growth, but gradually decreases as ripening sets in.

"Young shoots are also rich in betain, while the bark and wood (*Lycium* and *Atriplex*) contain very little. The root and leaves of *Amaranthus* contain 0.48 and 2.16 per cent respectively, and those of the sugar beet 0.95 to 1.2 per cent and 2.62 per cent betain. The seeds of all the plants tested were strikingly poor in this compound. The whole of the analyses appear to indicate a localization of betain at points of energetic physiological activity. The high percentages found in young leaves, shoots, and the root of a biennial plant such as sugar beet lead to the conclusions that betain plays an important part in the nitrogen metabolism of plants, but does not serve as a reserve foodstuff."

Investigations in regard to the betains occurring in plants, II, E. SCHULZE and G. TRIER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 4, pp. 258-290).—Continuing the work previously noted (E. S. R., 26, p. 713), the authors find that sunflower seeds (*Helianthus annuus*) in the form of sunflower cake contain very little betain, about  $\frac{1}{2}$  gm. of betain chlorid being obtained from 5 gm. of the cake. The leaves and stems of *H. tuberosus* yielded 1.5 gm. of betain chlorid from 6 gm. of material, while the bulbs gave 2 gm. of this salt from 25 gm. of material. The unripe seed coats of the vetch (*Vicia sativa*) yielded 1.33 gm. of betain chlorid from 488 gm. of dry substance, while the seed itself yielded from 100 gm. an average of 0.38 gm. of betain chlorid. Green vetch plants harvested before the blooming stage showed an average of 0.238 gm. of betain chlorid per 100 gm. of dry substance. The fresh green stems and leaves of peas (*Pisum sativum*) gave an average of 0.088 gm. of trigonellin per 100 gm. dry substance, as compared with 0.05 gm. of trigonellin from the seeds.

Black root (*Scorzonera hispanica*), the tubers of *Dahlia variabilis*, and chicory root (*Cichorium intybus*) all contained trigonellin, but the former two contained only very small amounts. From chicory root another base besides cholin was obtained, the amount, however, being so small that the product

could not be further studied. The leaves and stems of the young plants of *Stachys tubrifera* were found to contain stachydrin, which could be isolated very easily and in a pure state.

In addition to stachydrin, betonicin ( $C_7H_{13}NO_3$ ), a new base (which is provisionally considered oxystachydrin by the authors) was isolated from the leaves and stems of *Betonica officinalis*. Trigonellin and betonicin were obtained from the leaves and stems during the blooming and ripening stage from *S. sylvatica*. *Salvia pratensis* yielded cholin, but no stachydrin or other betain could be found. Young leaves of *Citrus aurantium* yielded a much larger amount of stachydrin than old leaves.

The authors hold that betains are by-products of plant metabolism, which no longer take part in the physiological processes of the plant.

Some further contributions in regard to the occurrence of betains in the plant kingdom, K. YOSHIMURA and G. TRIER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 4, pp. 290-302).—A continuation of the work noted above.

It is shown that no betain is present in *Glechoma hederacea* or *Fagara xanthoxyloides*, but cholin was noted in the former. Stachydrin was isolated from the leaves and stems of *Galopsis grandiflora* (in the optically inactive form, which is the first time it has been noted), and in lemon peel, but not in the leaves and stems of *Ajuga reptans* and rosemary flowers. Cholin was present in the latter 2 plants. Stachydrin and cholin were also detected in the flowers of *Chrysanthemum cinerariifolium*, while trigonellin was detected in the leaves and stems of *Mirabilis jalapa*.

Micro-organisms and fermentation, A. JÖRGENSEN (*London, 1911, 4, ed. rev.*, pp. XI+489, figs. 101).—This is the fourth revised English edition of this work, which deals with the physiology of fermentation. Among the topics discussed are the microscopical and physiological examination of material; biological examination of air and water; the various sorts of bacteria, molds, and yeasts, especially those of importance industrially; theories of fermentation; the action of yeasts; and the pure culture of yeast on a large scale.

Silage fermentation, W. M. ESTEN and C. J. MASON (*Connecticut Storrs Sta. Bul.* 70, pp. 40, figs. 3).—This investigation considers particularly the symbiotic fermentation which occurs during the preparation of silage with a view of determining the best conditions for preparing silage.

From some tests made in experimental silos (2-qt. milk bottles filled tightly with corn ground in a meat chopper and sealed), kept at temperatures of 40, 50, and 70° F., it appears that the latter temperature is the best one for producing preservative qualities, while at 40° the most destructive fermentation takes place. The temperature of 50° favors the production of propionic and butyric acids.

"This experiment explains why silage does not keep as well in cement, stone, or brick silos. The cement, stone, and brick conduct away the heat generated in a silo and the acid fermentation is checked unless the temperature of the air at siloing time is warmer than normal." According to this the appearance of the silage is not always the complete criterion for judging the quality of silage. Chemical and odor tests must be made in order to get a good idea of the quality.

The acidity of silage (chiefly lactic and acetic acids) was found to be in 5 years' testing nearly always 1 per cent (80 being the molecular weight considered in the determinations) for the total weight of silage, although at times it was over 2 per cent. The average is probably 1.5 per cent. In the miscellaneous examinations of the silage juice it is shown that at least 7 distinct varieties of yeast were present, all of which were facultative anaerobes. Among 13 colonies picked out from plates 10 were capable of fermenting dextrose, 3 fermenting dextrose and saccharose only, and 3 fermenting none of the 3

sugars. Succinic acid was found to be present in the fermented silage. Although acetic acid was produced in the silage the author was at a loss to explain why this acid is produced from the alcohol when an abundance of oxygen was not present.

Observations of the temperature of silage for a period of 5 years showed the highest temperature at the surface to be  $72.6^{\circ}$ . The highest interior temperature, taken 5 ft. from the bottom and from 1 to  $2\frac{1}{2}$  ft. from the edge, was  $86^{\circ}$ . "The highest temperatures [were] 6 in. from the surface. More than 3 ft. from the surface no temperature above  $82.40$  has been observed during the 5 years of observations on silage fermentations of all silos examined. High temperatures mean silage destruction when they are above  $100^{\circ}$ , and not silage formation. The best temperature for silage fermentation is from  $75$  to  $85^{\circ}$  F. because when these temperatures are found in a silo the best silage is found. At this temperature the acid is produced most rapidly and stops the growth of undesirable bacteria much sooner than at  $65$  to  $70^{\circ}$ . At a temperature below  $65^{\circ}$  during the fermentation stage a poor quality of silage is produced." The course of the bacterial growth and temperature curves of the silage were nearly parallel.

The number of acid-producing bacteria, of which the author makes 3 divisions, according to their fermentability, varied with the different years. A cane-sugar medium was found to be better than a lactose medium for differentiating acid from nonacid-producing bacteria. The methods of sampling silage and plating for bacterial counts are given.

As a conclusion the author points out the following: "Any farm product can be siloed providing there is sufficient sugar in the mixture to be fermented into acid to preserve it. The following mixtures silo successfully and make a very desirable and nearly balanced ration: Alfalfa and rye, clover and timothy or wheat or oats, oats and peas, and corn and cowpeas or soy beans. A round wooden stave silo, taking all things into consideration, has proven most satisfactory." A bibliography is appended.

**Agricultural chemistry**, R. OTTO (*Grundzüge der Agrikulturchemie*. Berlin, 1911, 2. ed. rev., pp. VIII+302, figs. 42).—A second edition, revised and enlarged (E. S. R., 10, p. 715).

**Chemical-technical methods of analysis**, edited by G. LUNGE and E. BERL (*Chemisch-technische Untersuchungsmethoden*. Berlin, 1911, 6. ed., rev. and enl., vols. 3, pp. XXI+1023, figs. 159; 4, pp. XIX+1061, pls. 4, figs. 56).—These volumes deal with general and special methods for analyzing fertilizers, feeding stuffs, gases, the products of gas manufacture, mineral oils, lubricating materials, fats and waxes, resins, balsams and gum resins, rubber, essential oils, the materials and products of cane and beet-sugar manufacture, starch, dextrin, alcohol, wine, vinegar, beer, paper, leather, citric acid, coal-tar dyes, and textile fibers.

**Theory and practice of volumetric analysis**, A. CLASSEN (*Theorie und Praxis der Massanalyse*. Leipzig, 1912, pp. IX+772, figs. 46).—This work, chiefly based upon the results obtained in the inorganic and electrochemical laboratory of the technical high school at Aachen, deals with indicators, measuring apparatus, titrametric systems, methods for saturation analysis, acidimetric methods, oxidation and reduction methods, iodometry, and analysis by precipitation.

**Note on the neutral permanganate method for the availability of organic nitrogen**, J. P. STREET (*Abs. in Science, n. ser.*, 35 (1912), No. 898, p. 427).—Adding 1 gm. of sodium carbonate to the neutral permanganate solution, just before adding the material to be examined, overcomes much of the loss in availability which occurs when high-grade ammoniates are mixed with large amounts of acid phosphate.

"Results on many organic ammoniates in presence of acid phosphate are given, showing that the method does differentiate between high and low-grade materials."

Activity of organic nitrogen as measured by the alkaline permanganate method, C. H. JONES (*Abs. in Science, n. ser., 35 (1912), No. 898, pp. 426, 427*).—After giving a detailed description of the alkaline permanganate method and the form now used for reporting the results, the author reports results on 14 different crude nitrogenous stock samples, 8 commercial fertilizers, and 13 mixtures of known composition, and interprets them from a standpoint of nitrogen activity.

"A method is also presented for determining the percentage of 'nitrogen in the organic and volatile matter.' Its application to fertilizers and crude stock as a means of determining whether the organic nitrogen present came from materials rich or poor in that element is discussed."

A method for determining phosphoric anhydrid colorimetrically, N. PASERINI (*Staz. Sper. Agr. Ital., 44 (1911), No. 1, pp. 5-10*).—Previously noted from another source (*E. S. R., 25, p. 614*).

A rapid volumetric method for the estimation of free sulphur, C. DAVIS and J. L. FOUCAR (*Jour. Soc. Chem. Indus., 31 (1912), No. 3, p. 100*).—The method is as follows:

"One gm. of the finely ground (60 mesh) sample (or its equivalent if previously dried) is dried in the water bath for an hour (if not already dried) and then transferred to a 250-cc. flask; 1.5 gm. of sodium cyanid and 50 cc. of absolute alcohol are added, and the contents are boiled under a reflux condenser for 2 hours. The alcohol is then completely removed by distillation, 100 cc. of hot water added, and the solution washed into a 250-cc. flask. The volume is made up to the mark—in the cold. To 25 cc. of this solution 75 cc. of water and 5 cc. of saturated iron alum solution are added; this is heated with constant stirring to 95° C., filtered into a 750-cc. beaker, and washed free from thiocyanate. When cool, 5 cc. of nitric acid is added, the solution made up, if necessary, to about 500 cc. with water, and titrated with twentieth-normal silver nitrate solution until the red color of the ferric thiocyanate completely disappears, or an excess of silver nitrate may be added and the solution titrated back with twentieth-normal thiocyanate. Should the sample contain thiocyanate, as is most likely in the case of spent oxid, a blank test should be conducted, the thiocyanate being extracted with water.

"Should it be required to ascertain the amount of matter, other than sulphur, soluble in carbon bisulphid, it may be determined by subtracting the sulphur content, found as above, from the figure obtained in the usual way for the percentage soluble in carbon bisulphid."

Detection of fluorids, E. RUPP (*Ztschr. Untersuch. Nahr. u. Genussmitl., 22 (1911), No. 9, pp. 496, 497, fig. 1; abs. in Analyst, 37 (1912), No. 430, p. 32*).—The substance to be tested is converted into ash and moistened in a platinum or lead crucible with 3 drops of water and 1 cc. of sulphuric acid. The crucible is then pitted loosely with a rubber stopper, through which a piece of glass rod passes. The lower end of the glass rod is moistened with a drop of water and the crucible with its contents heated for about 20 minutes.

If fluorids are present the rod becomes coated with a film consisting of silica, sodium silicofluorid, and calcium silicofluorid. If only traces of fluorid are suspected the portion of the glass rod below the stopper may be covered with a piece of rubber tubing, leaving only the end exposed to the action of the vapors.

Work published in regard to the composition, analysis, and adulteration of foods, A. J. J. VANDEVELDE (*Répert. Internat. Comp. Anal. et Falsif. Deurées Aliment., 10 (1909), pp. 104*).—This is a bibliography, which in some instances

includes abstracts, embracing the following topics: Foods and methods of food analysis, apparatus, water, milk and cream, fats and oils, cheese, flour and its derivatives, spices, sugars, beverages, legumes, fruits, meats, eggs, food adulteration, food legislation, etc.

Compendium for food chemists, A. BUJARD and E. BAIER (*Hilfsbuch für Nahrungsmittelchemiker*. Berlin, 1911, 3. ed., rev., pp. XVIII+730, figs. 10).—This publication (E. S. R., 12, p. 676) has been enlarged and brought up to date.

Netherlands food codex, A. J. J. VANDELVELDE (*Rev. Gén. Chim.*, 14 (1911), Nos. 17, pp. 269-277; 18, pp. 291-297).—A description of the official methods, chemical, microscopical, and physical, for the examination of the various flours and breads.

The valuation of edible fats by color reactions, H. SERGER (*Chem. Ztg.*, 35 (1911), Nos. 65, pp. 581, 582; 67, pp. 602, 603; 68, pp. 610-612).—This is a discussion in regard to the various color reactions thus far proposed for detecting adulterations in the edible fats. It is divided into a general part, which considers the Welman, Bellier, Serger, Kreis, and Wiedmann reactions, and a special part, which deals with specific reactions and considers cotton-seed oil (the Halphen, Berchi, and Hauchecorn reactions), olive oil, lemon oil, palm oil, coconut oil, peanut oil, and sesame oil. The reaction of sesame oil in butter has already been noted (E. S. R., 26, p. 212).

Examination of diseased potatoes with Reimann's potato balance, S. HALS (*Tidsskr. Norske Landbr.*, 18 (1911), p. 183; abs. in *Chem. Ztg.*, 35 (1911), No. 91, *Repert.*, p. 384).—Eighteen samples of potatoes which were affected with rot showed an average of 2.4 per cent less dry substance when determined by Reimann's balance than the figures obtained by the usual gravimetric method. The starch content in 9 out of 10 cases also showed 3 per cent less with the Reimann apparatus. These differences are probably due to the fact that the brown portions of the diseased potato contain proportionately less starch and more air spaces, so that their buoyancy in water becomes greater.

An electrical conductivity test for purity of maple sirup, J. F. SNELL (*Abs. in Science, n. ser.*, 35 (1912), No. 897, p. 379).—The method consists of diluting the sirup with 2 volumes of water and determining its electrical conductivity with the usual Wheatstone bridge and telephone receiver.

Among 57 sirups coming from Quebec, Vermont, and Ontario only 2 samples which were not obtained from the market gave conductivity figures under 200. The smallest value found was 110. Genuine sirups from the United States may be expected to give figures varying from 100 to 200, and Canadian sirups from 120 to 200.

Official methods for the examination of chocolate and cocoa (*Ann. Falsif.*, 4 (1911), No. 34, pp. 417-427, figs. 5).—These are the official French methods for determining water, ash, fat, sugar, matter insoluble in water, and starch in ordinary chocolates and cocoas, and the ash, casein, saccharose, lactose, etc., in milk chocolate. Some microscopic methods are included.

Detection of caramel in fermented beverages, V. PASQUERO and A. CAPPA (*Gaz. Chim. Ital.*, 41 (1911), II, No. 3, pp. 349-358; abs. in *Analyst*, 37 (1912), No. 430, p. 18).—The method rests on the fact that furfural can be obtained when caramel is subjected to distillation. The test is conducted as follows:

The beer, or other beverage suspected of containing caramel, is first neutralized with magnesium carbonate, and 100 cc. is distilled (after adding a few pieces of pumice stone) until a bulk of distillate corresponding to 75 cc. is obtained. The distillate is then made up to 100 cc., and 20 cc. shaken with 2 cc. of glacial acetic acid and 5 drops of colorless anilin in a colorimetric tube. If caramel is present a red color is produced within 15 minutes.

**Analysis of candied lemon peel**, F. HÄRTEL and A. KIRCHNER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 22 (1911), No. 6, pp. 350-353; *abs. in Analyst*, 37 (1912), No. 430, pp. 20, 21).—Twenty samples of candied lemon peel were examined with the following results: "Insoluble substances, 2.89 to 5.22 per cent; soluble extractives, 60.83 to 79.22 per cent; acidity (as citric acid), 0.04 to 0.2 per cent; sucrose, 14.3 to 48.5 per cent; starch sirup (anhydrous), 9.45 to 25.3 per cent; ash, 0.37 to 3.09 per cent; sodium chlorid, 0.02 to 0.09 per cent.

The process of manufacturing candied lemon peel is described.

**Technical drug studies by the division of drugs** (*U. S. Dept. Agr., Bur. Chem. Bul.* 150, pp. 51).—The following studies are included in this publication: Examination of Hydrogen Dioxid Solutions, by L. F. Kebler, L. E. Warren, and E. A. Ruddiman (pp. 5-23); The Purity of Glycerin, by L. F. Kebler and H. C. Fuller (pp. 24-35); Notes on Two Important Alkaloidal Reactions, by H. C. Fuller (pp. 36-40); The Separation and Identification of Small Quantities of Cocain, by H. C. Fuller (pp. 41-44); The Determination of Molybdic Trioxid, by B. Herstein (pp. 44-46); A Method for Testing Ammonium Salts, by B. Herstein (pp. 47, 48); Character of Samples of Beeswax Submitted with Bids, by L. F. Kebler and F. M. Boyles (pp. 49-51).

**Biochemistry of colostrum**, S. ENGEL (*Ergeb. Physiol.*, 11 (1911), pp. 41-103, figs. 8).—This is a critical review of practically all the work done in regard to the biochemistry of colostrum. It includes the colostrum of the cow, buffalo, goat, sheep, horse, and man.

**Investigations in regard to the hemolytic power of cow's colostrum**, W. KÖEBELE (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 61 (1912), No. 7, pp. 561-589).—The colostrum from some cows contains hemolytic amboceptor and complement. Hemolytic amboceptor is present the second day post partum. Indications for complement were noted up to the fifth day, but most often only to the third day.

According to this author, the hemolytic amboceptors and complement in colostrum are nothing else than constituents of the normal bovine serum which have filtered through the blood vessels into the mammary gland. These bodies are present in both the initial and end colostrum, and in practically the same amounts.

**Note on the gravimetric estimation of phosphorus in milk**, E. H. MILLER (*Analyst*, 36 (1911), No. 429, pp. 579-583).—"The conclusions drawn from the results are that the usual methods of estimating phosphorus in milk—viz, (1) By precipitating as magnesium ammonium phosphate after removing the lime as oxalate, and weighing as magnesium pyrophosphate; (2) by precipitating as magnesium ammonium phosphate in the presence of lime, holding the same in solution with ammonium citrate, and weighing as magnesium pyrophosphate; and (3) by precipitating as ammonium phosphomolybdate, dissolving and reprecipitating as magnesium ammonium phosphate, and weighing as magnesium pyrophosphate—give results that differ from Carius's method only by about 0.01 per cent. In the case of concentrated and sweetened condensed milk and milk powders it is evident, however, that it is preferable to treat the milk solids by Carius's method, and estimate the orthophosphoric acid in the solutions so obtained. It might be mentioned that the close agreement between the results seems to show that no appreciable quantity of phosphorus is volatilized during the incineration of the milk. This has also been pointed out by Bordas and Touplain" (*E. S. R.*, 25, p. 713).

**Comparison of methods of sampling cream for testing**, C. E. LEE and N. W. HEPBURN (*Illinois Sta. Bul.* 153, pp. 543-574).—The purpose of this investiga-

tion was principally to determine the efficiency of the various methods of sampling in use and their relation to actual creamery practice.

The kinds of samples taken were individual, ordinary composite (obtaining a sample consisting of a representative amount of cream from each delivery of a single patron for 15 days), and proportionate (samples taken in proportion to the amount of cream received at the creamery). For the whole experiment 40 per cent 18 gm. bottles, graduated to  $\frac{1}{2}$  per cent, were used. The samples were weighed on a scale of the creamery torsion type.

The duplicates obtained when testing the cream by the same or different testers were only reasonably variable. "In samples reported 87.7 per cent were exact duplicates or checked within  $\frac{1}{2}$  per cent, 9.8 per cent varied 1 per cent from the individual, while 2 $\frac{1}{2}$  per cent showed a variation of more than 1 per cent." A greater latitude of variation between composite and individual samples was noted than between 2 sets of composites. The variation, however, was evenly divided. The composites of one of the authors (Hepburn) showed tests of 36.4 per cent above and 41.99 per cent below the individual samples.

"Two series of composites taken in the same manner showed the following tendency for variation: 63.73 per cent were exact duplicates, or varied but  $\frac{1}{2}$  per cent; 17.6 per cent varied 1 per cent; 6.33 per cent varied 1.5 per cent; 7.52 varied 2 per cent; 2.1 per cent varied 2.5 per cent; while 2.8 per cent varied more than 2.5 per cent. During the winter months 41.87 per cent of the composites tested lower than the individual against 35.38 per cent testing higher. During the summer months 33.91 per cent tested lower against 43.16 testing higher."

The results of long-time averages, that is, during a period of 6 months, show that one of the testers (Lee) had only 15.7 per cent of the samples vary more than  $\frac{1}{2}$  per cent, while with the other tester (Hepburn) the variation was 15.9 per cent. "Under the proportionate system, for a period of 6 months, 24.75 per cent of the samples varied more than  $\frac{1}{2}$  per cent." When based on the period of 1 year "only 5.95 per cent of Lee samples varied more than  $\frac{1}{2}$  per cent, while during the same length of time 7.78 per cent of Hepburn's varied more than  $\frac{1}{2}$  per cent. Results from the yearly average butter fat show 14.52 per cent of composites below the individual and 7.7 above by Lee, and by Hepburn 15.34 per cent below and 7.78 above. These results are closer than the results obtained by duplicate testing."

All of the above results were corroborated from the total weights of butter fat, which showed that the variation between the individual and composite samples was 0.27 (Lee samples) and 0.16 (Hepburn samples) per cent. According to these findings, reasonable allowances should be made for the differences in duplicate samples obtained by the same or different testers.

**The aldehyde figure of butter.** E. H. MILLER (*Analyst*, 37 (1912), No. 431, pp. 50, 51).—Formaldehyde combines with milk proteins to form additive compounds, probably of the type  $R-\begin{matrix} \text{NCH}_2 \\ \text{COOH} \end{matrix}$ , which increase the acidity of the

milk or cream in proportion to the total nitrogen present. This fact has been employed successfully by Richmond (E. S. R., 18, p. 8; 22, p. 309) for estimating the proteins in milk, and the author sought to apply it to the protein content of butter. The results obtained with butter 1 month old show that it can be employed for this purpose.

The method used in the investigation was as follows: "Approximately 10 gm. of butter is weighed into a tared beaker, which is placed in a water bath at 60 to 70° C., until the butter is completely melted. Twenty-five cc. of water at about 65° is added, and followed by 1 cc. of a 0.5 per cent solution of phenolphthalein. The contents are well agitated. Approximately twentieth-

normal alkali is then run in until a faint permanent pink tint is formed. If it is found that the end point is masked by the yellow color of the butter fat, the contents of the beaker should be allowed to settle, and the bottom aqueous layer observed, and the addition of alkali continued until the pink tint is obtained. Five cc. of strong formaldehyde solution is next added, and the contents of the beaker well agitated; twentieth-normal strontia is then run in until the pink tint is again produced in the aqueous portion.

"The number of cubic centimeters of twentieth-normal alkali used in the second titration, less the amount equivalent to the acidity of the formaldehyde solution added, is proportional to the protein present. One cc. of twentieth-normal strontia is equivalent to 0.01355 gm. of protein nitrogen, assuming the proportion of casein to albumin to be 7:1."

Procedure for determining the sugar content of bagasse, J. J. HAZEWINKEL, J. S. DEHAAN, and G. L. VAN WELIE (*Arch. Suikerindus. Nederland. Indië*, 19 (1911), No. 49, pp. 1687-1691; *Meded. Proefstat. Java-Suikerindus.*, 1911, No. 13, pp. 381-385; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 3, pp. 142, 143).—This is a method based on the fact that proper results can only be obtained if the basic lead acetate solution is added after boiling. Defecation before boiling yields higher results.

In regard to the changes which take place in sugar beets during storage, G. FRIEDL (*Kisérlet. Közlem.*, 14 (1911), No. 6, pp. 793-819).—The losses of sugar in beets during storage are due in part to the absorption of large amounts of water, which dilute the juice, but mainly to the consumption of saccharose by the respiratory process of the beet. This latter loss, however, can not be prevented unless the vital processes of the beet are checked or destroyed, and this can only be accomplished by impracticable methods as freezing or drying the beet. Invert sugar was found to be the intermediary product of saccharose destruction. The energy of respiration is dependent upon various factors. The nitrogen content of the beet was found to be more stable than the saccharose, and only at the end of the storage period was there a perceptible cleavage of protein. Of the cleavage products glutamin was formed to the greatest extent. No transformation of glutamin to glutamic acid was noted.

The comparative influence of water and vinasse upon the pulp residues obtained from the manufacture of beet sugar and from the distillery, L. AMMANN (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 6, pp. 366-369).—The pulp obtained from the sugar-beet distillery is considered superior as a feed to that obtained from the beet-sugar refinery. This, however, is not regarded as due to the apparatus employed for the extraction of the sugar, but rather to the liquid which is utilized for extracting the sugar.

The desiccation of potatoes and the uses of the product, C. C. MOORE (*Abstr. in Science, n. ser.*, 35 (1912), No. 897, p. 380).—"The desiccation of potatoes has been commercially developed in Germany, but the product has not been suitable for the manufacture of starch. Investigations have shown that a dried potato product can be prepared in a way suitable for starch manufacture. Owing to the greater degree of fineness to which the dried product can be reduced, over 90 per cent of the starch can be separated in the usual washing and decantation methods, as against a recovery of 65 to 75 per cent of starch when potatoes are ground in a fresh state."

Forest chemistry, 1909-10, P. SINGH (*Ann. Rpt. Bd. Sci. Advicc India, 1909-10*, pp. 26-30).—This is a report of the work done by the assistant chemist of the Imperial Forest Research Institute of India, including the manufacture of mangrove tannin extract from *Rhizophora mucronata*, distillation of *Blumea balsamifera* and *Rhusa* grass oil, manufacture of shellac, analysis of shellac, turpentine, colophony, *Canarium bengalense*, and camphor from *Cinnamomum glanduliferum*, and the refining of Koosam oil for soap making.

## METEOROLOGY—WATER.

**The climate of Ohio.** J. W. SMITH (*Ohio Sta. Bul.* 235, pp. 185-209, figs. 15).—The available records on temperature, precipitation, humidity, sunshine, first and last frosts, and wind movement are summarized in tables and charts.

It is shown that the average annual temperature for Ohio during the period from 1883 to 1910, inclusive, was 59.7° F. July is shown to be the warmest month, with an average temperature of 73.1°; January the coldest month, with a mean temperature of 27.7° F. At some time during this period the temperature went below zero in each month from November to March, inclusive, and below freezing in every month in the year except July. The average annual precipitation for the State as a whole during the period from 1854 to 1910, inclusive, was 38.89 in. June has shown the greatest average rainfall, with 4.13 in.; October the least, with an average of 2.52 in. "The snowfall averages less than 20 in. in the extreme southern portion of Ohio, and over 60 in. in northeastern counties. The prevailing winds are from the southwest over most of the State, and vary slightly with the season." The average number of rainy days is 122.

"Ohio is in the path of a large part of the general low pressure or storm areas which move across the United States from west to east. These areas move at an average speed of 600 miles in 24 hours and are preceded by southerly winds and higher temperature and followed by northerly winds and lower temperature. They are usually accompanied by cloudy weather and precipitation and each storm causes an average of from one to two rainy days at each place as they pass. . . .

"As there is an average of two of these storm areas each week with fair weather periods between them, it follows that the change in weather conditions is rather rapid. One or two days of stormy weather preceded by higher and followed by lower temperatures, succeeded by one or two days of fair weather preceded by lower and followed by higher temperatures, to be repeated in turn, makes up the usual routine for the week.

"Yet Ohio is far enough from the coast so that the damaging Gulf and Atlantic storms lose very much of their severity before reaching [the State]. The northwestern cold waves pass across the State with sufficient intensity to ventilate and invigorate the towns and cities and send their health-giving winds into all parts of the State, and yet the cold waves are not so severe in Ohio as in corresponding latitudes in the Mississippi and Missouri valleys."

**Meteorological observations at the Massachusetts Agricultural Experiment Station.** J. E. OSTRANDER and R. N. HALLOWELL (*Massachusetts Sta. Met. Buls.* 279, 280, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1912. The data are briefly discussed in general notes on the weather of each month.

**The weather of 1911 at the Midland Agricultural and Dairy College, Kingston-on-Soar, Notts.** F. WAKERLEY (*Midland Agr. and Dairy Col. Bul.* 7, 1911-12, pp. 61-66, figs. 2).—The record of air and soil temperature, rainfall, frosts, and other weather conditions for 1911 is compared with those of the previous 6 years.

This shows that at this institution, which is situated at Kingston-on-Soar, Nottinghamshire, the mean temperature was 49.6° F., a little above the average; the maximum, 95.3° (on August 8), the highest on record; and the minimum, 14.2°, on February 1. The annual rainfall, 18.01 in., was much below the average of 25 in. The number of rainy days was 156 as against 204 the previous year.

**Report of the work of the station of agricultural climatology of Juvisy during 1910.** C. FLAMMARION (*Bul. Mens. Off. Renseign. Agr. [Paris]*, 11 (1912),

No. 4, pp. 460-477, figs. 7).—This includes the usual summaries of observations on temperature of the air, soil, and underground water, atmospheric pressure, humidity, rainfall, sunshine and cloudiness, and wind. There is also a brief discussion of the late summer and warm autumn characteristics of the climate of the region, as illustrated by conditions during the summer and fall from 1906 to 1910. The season of 1910 was wet, cold, and very unfavorable to crops.

Weather forecasts for 1912 in Russia, I. SAVIZKII (*Selsk. Khoz.*, 1912, No. 10, pp. 462-464; abs. in *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases*, 3 (1912), No. 5, pp. 1097, 1098).—The success of long-time weather predictions in Russia is discussed. It is stated that the propitious weather of the season of 1909 was predicted 3 months before harvest, the drought of 1911 in September, 1910. The predictions for 1912 are given in some detail.

Our weather, J. S. FOWLER and W. MARRIOTT (*London*, 1912, pp. XI+131; rev. in *Nature [London]*, 89 (1912), No. 2220, p. 267).—This is one of a series of elementary books. After a brief introductory chapter explaining the practical need of a popular book on the weather, there follow chapters on pressure, temperature, humidity, wind, and allied phenomena, as well as on weather forecasting, the upper air, phenological observations, and weather proverbs and rhymes.

Smoke.—A study of town air, J. B. COHEN and A. G. RUSTON (*London*, 1912, pp. 86, figs. 35).—This book, the more important agricultural features of which have already been noted from another source (*E. S. R.*, 26, p. 727), deals with (1) solid products of combustion, (2) gaseous impurities, (3) town fog, (4) dispersal of soot, (5) influence of coal smoke upon health, (6) analysis and manuring value of soot, (7) analyses of Leeds rain water, and (8) sootfall of London.

Combined nitrogen in rain, C. T. GIMINGHAM (*Chem. World*, 1 (1912), No. 5, pp. 155, 156).—The various observations on this subject are summarized, the general conclusion being "that in rural districts the soil receives annually something between 5 and 6 lbs. of nitrogen per acre in the rain; and this, though a small amount, is by no means negligible in experimental work."

Ponds in agricultural districts, E. A. MARTIN (*Jour. Bd. Agr. [London]*, 19 (1912), No. 1, pp. 17-20).—The making and care of ponds for storage of water in time of drought are briefly discussed. It is shown that under the conditions prevailing in parts of England upland ponds dry up less rapidly than lowland ponds.

Sewage disposal, G. W. FULLER (*New York and London*, 1912, pp. XV+767, figs. 80).—This book records recent advances and gives the present status of both theory and practice in the field of sewage disposal. It deals essentially with American practice, particularly as observed in the author's experience, although European practice is not entirely ignored. The subject is treated from the viewpoint mainly of the operator of disposal works.

"The book is divided into 4 parts of approximately equal size. The first part is devoted to a somewhat lengthy description of the composition of sewage and the behavior of bacterial and biochemical processes in the decomposition of sewage. The importance of oxygen and deoxygenation, not only as a means of measuring the strength of sewage but in relation to proper conditions of the flow of sewage through collecting systems and various disposal devices, is discussed rather fully. The practical purpose of this is to show how to prevent or lessen 'putrefaction' with its objectionable odors. The significance of sewage disposal problems from various angles is explained in detail. In particular the relation of sewage bacteria to shellfish pollution is discussed with thoroughness at a time when this problem is being actively considered by federal

and state authorities, who differ from the oyster growers in their views on several points.

"The second part of the book is devoted to a recital of American experience in the disposal of sewage by dilution in inland streams, lakes, tidal estuaries, and oceans. Although several early American reports upon this subject were prepared with much thoroughness, they have not received the attention in recent years that they are entitled to. The prevailing method in America of disposing of sewage by dilution has been applied in a faulty way in many instances, and corrective measures are needed. It is not necessary, however, in a majority of cases, to abandon this method in favor of complete purification. The limiting factors and conditions in present practice are described at length, with suitable summaries.

"The third part of this book deals with what have been generally called preparatory arrangements for the treatment of sewage. Screening, settling tanks, septic tanks, chemical precipitation tanks, electrolytic treatment, and strainers are discussed in much detail, particularly septicization in two-story tanks. Résumés as to their present standing are given for each device.

"The fourth part deals with filtration matters with a view to recording present practice. The closing pages of the book are devoted to aeration, sterilization, and ozonization processes as they are now understood, with a few explanations as to institutional and residential plants, and a final comparative summary of general costs and efficiencies."

The chapter on broad irrigation is of special interest from an agricultural standpoint. In a résumé of this chapter it is stated that "in America broad irrigation or sewage farming is not practiced to-day even in the arid regions so as to give satisfactory results for the sanitary disposal of sewage. There may be scattering exceptions to this statement, but an examination of the present facts does not bear out earlier reports that broad irrigation is really used regularly and carefully in numerous places.

"Objections to the method have increased rather than decreased in recent years. These relate to objectionable odors, prejudices against the use of sewage in growing vegetables, and to the transmission of disease germs by flies and other insects.

"Experience shows that only nominal aid financially has been received from the use of sewage in broad irrigation.

"The present outlook is that broad irrigation or sewage farming is decidedly on the wane with little prospects of adoption even in the arid districts except perhaps for an occasional project where local conditions are unusually favorable."

**Practical methods of sewage disposal**, H. N. OGDEN and H. B. CLEVELAND (*New York and London, 1912, pp. VI+132, pl. 1, figs. 51; rev. in Engin. News, 67 (1912), No. 24, p. 1157*).—This book explains the increasing need for more efficient means of sewage disposal in country homes and rural communities. It deals with the individual system as distinguished from the community or municipal plan of disposal. "The higher standards of living which have made themselves felt throughout the rural community have demanded in farm-houses and country homes sanitary conveniences which have hitherto been wanting.

"Gradually every house is using more and more water for various purposes, and living conditions, which in the past tolerated a scanty supply drawn from a pump, are no longer endured. The increased water supply and the demands of extended plumbing mean a greater amount of sewage—so great an amount that, in many cases, soils which could receive and digest the waste waters

from houses supplied by wells are clogged and made impervious by this greater amount.

"Further, the danger to wells from the infiltration of cesspools is more feared, and it is understood as never before that in order to maintain the highest degree of health in a family the drinking water used must be above suspicion and not subject to contaminating influences in the vicinity.

"Again, communities are being aroused to the intrinsic value of maintaining streams in a pure condition—partly because of the value of fish and ice coming from the streams themselves, and partly on the broad ground that water courses belong to the country as a whole, and must be kept pure for the sake of succeeding generations, not spoiled for them on account of the selfishness of a few at the present time.

"Thus it is that to-day the problem of sewage disposal, while arousing general interest, is recognized as one which requires more than the common sense of an average person, that the force and principles involved are understood to be not those in common use, and that, for successful disposal of sewage, special knowledge and judgment are required."

The book divides sewage purification into two processes, (1) preliminary sedimentation, as for example, by means of the Imhoff or Emus tank, and (2) final disposal by subirrigation, sand filter, contact bed, or sprinkling filter. The sprinkling filter system is considered more complicated, and less suitable for this reason, than the others.

The merits and faults of broad irrigation as a method of disposing of sewage are quite fully set forth. With suitable soil and slope, and proper care, this method is deemed efficient and productive of increased crops, but it requires watchful care and much labor to prevent offense and danger to health.

The design, construction, and cost of the sewage systems are presented in text, tables, and sketches.

### SOILS—FERTILIZERS.

Present problems in soil physics as related to plant activities, B. E. LIVINGSTON (*Amer. Nat.*, 46 (1912), No. 545, pp. 297-301).—In this paper, which was presented in the symposium on problems of the soil at the Washington meeting of the American Association for the Advancement of Science, the author considers the soil moisture relations of the underground parts of the plant to plant activities. The following summary is given:

"The soil water relation is of fundamental importance if we are some time to know about and be able to predict and control plant processes. The moisture of the soil, as well as its other features, is most profitably to be studied as plant environment, the relations which obtain between plant activity and soil phenomena comprising a fundamental and primary requirement for the scientific advance of our knowledge. The physical nature of the subterranean environment of terrestrial plants is effective in controlling plant activities, mainly with regard to the possible rate of delivery of water by the soil to unit area of absorbing roots. It is highly desirable to study this power of water delivery with reference not only to the growth of plants, but also to other soil characteristics, some of which are already commonly measured. The whole problem of the physics of the subterranean surroundings of rooted plants awaits the development of an instrumentation which will not necessitate the preliminary destruction of some of the most important soil properties before the soil can really be studied."

The temperature of the soil under different conditions, W. R. DUNLOP (*Agr. News [Barbados]*, 11 (1912), No. 261, p. 135).—Observations on temperature of

different soils in dry and in wet localities, and as influenced by depth, color and texture, fertilizers, and cultivation, are reported.

Soils in a wet locality maintained a lower temperature than those in a dry locality. This is attributed to the cooling effect of the rainfall with its subsequent evaporation, to direct sea breezes, and to the absorption of radiant heat by clouds.

The temperature of the soil at 3 in., at 6 a. m., was 72° F. and increased to a maximum of 91° at 1 p. m. There was a quick drop after sunset. The temperature at 6 in. remained more constant, and was lower during the day than at 3 in. but higher at night. "At a depth of 1 ft., the temperature remained nearly constant during the day, but it was 2° lower at night than during the day. The maximum temperature was 85°. At a depth of 2 ft., the temperature was 83° and remained constant day and night. A heavy shower of rain lowered the temperature by 1° on another occasion. . . ."

"The sand plat was warmer at 1 p. m. than the soils of the other plats, and was cooler at 7 a. m. The temperature of the untouched sand at 1 p. m. was 99°; that of the cultivated sand 90°. The temperature of the dry sand had a diurnal range of 26°; this was considerably greater than that of the air. In the case of all the plats, the effect of water in leveling up the specific heats was clearly indicated. At 1 p. m. the clay was warmer than the humus plat, but cooler at 7 a. m. The lime plat (untouched) was 13° cooler at 1 p. m. than the sand plat (untouched), and the lime plat also possessed the lowest diurnal range, which amounted to 6 to 8°."

Cultivating, particularly forking and plowing, had a cooling effect. "Rolling warmed the soil in dry weather, but had the opposite effect when the land was wet. As regards ridging or banking up, the important fact was brought out that land cultivated in this manner from east to west is at least 3° warmer during the day than when the soil is ridged north and south. At a depth of 3 in. the difference would be at least 6°. The well-known fact that wind cools the soil was also supported by observations made in sheltered and unsheltered places. The soil under pasture was rather cooler than arable soil, and covering arable soil with light trash lowered the temperature during the day by 4°. Soil shaded with cacao plants was 11° cooler at 1 p. m. than soil exposed to the sun, and at 7 a. m. it was cooler by 3°."

Studies of the heat conductivity of some soil types, H. KARSTEN (*Internat. Mitt. Bodenk.*, 1 (1912), No. 6, pp. 524-543, figs. 4).—Studies of the theory of heat transference in masses of spherical bodies, and determinations of the same in soils of different structure and moisture content, are reported, using a modification of the Christiansen apparatus. The theory that the heat conductivity of spherical, homogeneous bodies of the same size is independent of the length of their radii was substantiated. The heat transference was influenced by the structure and particularly by the moisture content of the soil.

Suspensions and the phenomena of absorption, S. ARRHENIUS (*Rev. Sci.* [Paris], 49 (1911), 1, No. 15, pp. 449-456).—This is a mathematical discussion of the laws and phenomena of absorption in solutions, based on investigations by different authors.

The plant and the salts of the soil, N. M. TULAIKOV (*Zhur. Opytn. Agron.* [Russ. Jour. Expt. Landw.], 13 (1912), No. 1, pp. 27-53, figs. 4; abs. in *Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 6, p. 1297)—It is stated as a result of studies that the water-soluble nonnutrient salts of the soil had a decided influence on the growth of vegetation, both in its earliest and in its last stages of development.

In the earliest stages of growth the action of the salts was physical, in that it brought about a certain degree of osmotic pressure and thereby regulated

the absorption of water by the germinating seeds. Individual peculiarities of the salts were only slightly discernible, and isotonic solutions of different salts produced very similar effects. The toxicity of the different salts to plants as a rule manifested itself in plasmolysis of the contents of the root cells. In some cases the salts seemed to have a chemical action, destroying the structure or coagulating the contents of the surface cells of the roots.

Variations in the content of nonnutrient salts in the soil solutions were clearly reflected in the character of the growth of the plants and in the yield, there being in solutions of high concentration and osmotic pressure quicker changes in phases of growth, a reduction in total yield and yield of grain, and, on the other hand, a marked increase in the amount of nitrogenous substances in the plant and particularly in the amount of albumin in the grain (of wheat). The effect of the osmotic pressure of the soil solution on the production of nitrogen in the wheat grain was especially marked during the period of filling and ripening of the kernels.

**The biological absorption of phosphoric acid in the soil, A. I. DUSHECHKIN** (*Zhur. Opyta. Agron. (Russ. Jour. Expt. Landw.), 12 (1911), No. 5, pp. 650-668; abs. in Zentbl. Agr. Chem., 41 (1912), No. 5, pp. 305, 306; Jour. Chem. Soc. [London], 102 (1912), No. 597, II, p. 677*).—Studies of the biological absorption of phosphoric acid from solutions in soils receiving starch and treated with thymol and with chloroform are reported. Tests of the influence of sodium nitrate on the biological absorption were also made.

From the results of these studies it is concluded that in addition to the physico-chemical absorption of phosphoric acid there was a biological absorption. The latter increased with the starch content of the soil and also with the length of time. It was more pronounced with the larger applications of phosphoric acid. The fixation of phosphoric acid by the micro-organisms took place not only from the readily soluble forms but from the difficultly soluble phosphoric acid of the soil as well, and was stimulated by additions of sodium nitrate. Bacterial fixation of phosphoric acid was accompanied by a dissolving process.

**The origin of loess, C. L. HENNING** (*Internat. Mitt. Bodenk., 1 (1912), No. 6, pp. 518-523*).—Different theories regarding the origin of loess deposits are stated, and the American literature is briefly reviewed with particular reference to the work of E. E. Free of the Bureau of Soils (E. S. R., 25, p. 424).

**Soil fertility, C. G. HOPKINS** (*Illinois Sta. Circ. 157, pp. 16*).—This is an address delivered before the Illinois State Farmers' Institute in which the author discussed the more important methods and results of Illinois soil investigations which support the conclusion "that for the most economic and profitable systems of permanent agriculture in general farming, we should make large use of natural materials including for normal soils ground limestone, raw rock phosphate, and organic matter to be supplied by plowing under legume crops and other crop residues, either directly or in farm manure."

**Cooperative studies of Rhode Island soil deficiencies, H. J. WHEELER ET AL.** (*Rhode Island Sta. Bul. 149, pp. 47-79, pls. 2*).—Accounts are given of experiments begun in 1890 on a number of farms in different parts of the State with a view of determining their lime and fertilizer requirements. The results have previously been reported in large part in bulletins and reports of the station (E. S. R., 15, p. 665; 19, p. 317; 23, p. 21).

**Soil mapping and soil analyses, D. J. HISSINK** (*Cultura, 24 (1912), Nos. 283, pp. 128-132; 284, pp. 158-163*).—This is a summary of the work of Hall and Russell with reference to the soils of southeast England (E. S. R., 26, pp. 118, 119), and is offered as a criterion by which to determine the expediency of conducting agricultural soil surveys in the Netherlands.

**Investigations on pine-covered sand dune soils, K. VOGEL** (*Internat. Mitt. Bodenk.*, 1 (1912), No. 6, pp. 495-517, pls. 3).—The pine forests of Melchow near Eberswalde having shown a marked difference in productiveness, the author made a series of mechanical and chemical analyses of samples of soil from areas supporting a vigorous forest growth and from devastated areas, parts of which had been reforested, with a view of determining the limiting element of plant food. A comparison was made of the results of these analyses with those of forest soils by other investigators.

The results showed that these sand dune soils were low in mineral constituents but that, notwithstanding this fact, they produced heavy crops of pine trees where sufficient amounts of nitrogen and humus were present in the soil. The yield of pine trees was in direct proportion to the nitrogen and humus content of the soil, and it is believed, therefore, that for the improvement of these dunes, and probably also of most of the forest soils of northern Germany, which have been shown to contain at least an equally high mineral content, the application of mineral fertilizers is not necessary but that consideration should be given to the matter of increasing and conserving the nitrogen and humus content of the soil.

**Studies of the tillable soils of Roumania, G. MURGOEI** (*Internat. Mitt. Bodenk.*, 1 (1912), No. 6, pp. 517-562).—References to the more important literature on the subject are given, with a brief discussion as to the scope of the different works.

**The composition of sandy soils of Tripoli, A. MENOZZI** (*Agr. Mod.*, 13 (1912), No. 6, pp. 81-83).—The results of mechanical and chemical analyses of soil samples from different parts of Tripoli and from Sfax in Tunis, including tests of the absorption of ammonia and phosphoric acid from solutions, are reported and briefly discussed.

**Some cotton soils of the Nyasaland and Uganda protectorates** (*Bul. Imp. Inst. [So. Kensington]*, 10 (1912), No. 1, pp. 55-74).—The results of mechanical and chemical analyses of a number of samples of typical soils from different parts of the regions to determine their suitability for cotton growing are reported and briefly discussed. The soils, in general, contained sufficient amounts of plant-food constituents. In some cases, however, the percentage of nitrogen and of phosphoric acid was slightly below the average for good cotton soils. The mechanical condition of the soils was satisfactory.

**The pinery and orchard soils of the Bathurst Division, Cape Province, J. LEWIS** (*Agr. Jour. Union So. Africa*, 3 (1912), No. 3, pp. 357-371).—The pineapple crops of the region having shown a steady deterioration, the author made a series of analyses of typical soils and of average fruit and plants with a view of determining their plant-food requirements. Analyses of apple and orange soils were also made.

The results, in general, showed that, although the soils may be considered of medium quality, the pineries were in every case deficient in one or more of the necessary soil constituents. The use of ordinary mineral fertilizers is recommended to supply the deficiency. The apple and orange soils were generally poor in lime, potash, and phosphoric acid, and a few were also poor in nitrogen.

**[Analyses and determinations of moisture of Queensland soils], J. C. BRÜNNICH** (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1909-10, pp. 44, 50-56).—Analyses of soils of newly opened banana and pineapple districts calculated to pounds of plant food per acre for a depth of 1 ft., and determinations of soil moisture at various depths and in relation to cultivation are reported.

The soils, in general, were well supplied with the mineral constituents of plant food. It is stated that the value of the soil analyses would be very much

increased by more complete data as to the origin of the soils, and the starting of detailed soil surveys by districts has therefore been recommended.

The results of the moisture determinations show "that in the uncultivated block very little of the water which fell during December and January was absorbed by the soil, and that in spite of the good rain the amount of moisture remained practically the same at the various depths of 6 in., 1 ft. 6 in., 2 ft. 6 in., and 3 ft. 6 in. during the months of December, January, and February. Very heavy rain fell before the March sample was taken, and the soil from the top layer right down to 3 ft. 6 in. benefited by this rain, but the moisture again was very rapidly lost after a few weeks without rain. In the cultivated land the conditions of absorbing moisture were more favorable, and again the loss of moisture by evaporation was considerably diminished. Very striking, however, is the difference caused by the Campbell system of cultivation and also in the land worked bare fallow, which cause the moisture to be completely conserved in the top layers, and almost completely prevented the loss by evaporation during months of dry weather."

**Fertilizers and crops**, L. L. VAN SLYKE (*New York and London, 1912, pp. XIV+734, pl. 1, figs. 132*).—This book, by the chemist of the New York State Station, attempts to make "practical application of the results of investigation to the use of plant food in the growing of crops." It embodies the main results of investigation in this country and abroad, including the author's studies, observations, and experience in this field during the past 25 years.

"The purpose has been not merely to give information but to present it in such a systematic way as to show certain fundamental relations and make clear, as far as possible, the reasons underlying every practice suggested. . . .

"In the selection and arrangement of the materials, the writer has kept in mind the needs of practical farmers as well as those of classes in agricultural colleges and high schools."

The book is divided into 4 parts, part 1 (pp. 1-233) dealing with factors of soil fertility, part 2 (pp. 235-393) with sources and composition of materials used as fertilizers, part 3 (pp. 395-507) with factors in the selection of fertilizing materials, and part 4 (pp. 509-710) with the practical use of fertilizers in the growing of individual crops.

**Commercial fertilizers and agriculture of the Alps**, O. KERLER (*Deut. Landw. Presse, 39 (1912), Nos. 33, pp. 391, 392, figs. 4; 34, pp. 402, 403, figs. 7*).—This is an account of the agricultural practices of the Alps and of experiments with barnyard manure and commercial fertilizers, showing that the practice of supplementing barnyard manure with a phosphatic fertilizer greatly increased the yield of crops, and in turn enabled the farmer to keep more stock and thus produce larger amounts of manure. Complete mineral fertilizers are recommended only where sufficient manure to fertilize the entire farm is not produced.

**Calcium cyanamid as compared with nitrogenous fertilizers**, L. R. DA SILVA (*Rev. Agron. [Portugal], 9 (1911), No. 1-6, pp. 94-107*).—Comparative tests of calcium cyanamid, sodium nitrate, and ammonium sulphate with various crops are reported.

**The constitution of basic slag**, HARTLEB (*Ztehr. Öffentl. Chem., 17 (1911), No. 20, pp. 381-384; abs. in Chem. Abs., 6 (1912), No. 5, p. 663*).—The author maintains substantially that Blome's experiments with fusions of tricalcium phosphate, lime, and silica (E. S. R., 25, p. 121) throw no light on the constitution of Thomas slag or on the cause of the increase in citrate-solubility of the phosphoric acid of the slag when it is fused with sand.

**The influence of lime on cultivated soil** (*Arch. Suikerindus. Nederland. Indië, 20 (1912), No. 13, pp. 379-383*).—This is a brief review of the investigations on this subject by Thaer (E. S. R., 25, p. 823).

The trade in cotton-seed meal, E. H. JENKINS (*Connecticut State Sta. Bul.* 170, pp. 4).—The plan worked out by the station, by which the dealer and consumer of cotton-seed meal may be assured of its quality, is described.

Experiments with gas purification residue as a weed killer, insecticide, and nitrogenous fertilizer, H. VON FRIEDTZEN (*Fähling's Landw. Ztg.*, 61 (1912), No. 8, pp. 285-297).—The results were not very favorable to the use of the material for the purposes named.

Tannery refuse as a fertilizer, H. W. HEALY (*Rural New Yorker*, 71 (1912), Nos. 4151, p. 622; 4152, p. 643).—The method of preparation, nature, and fertilizing value of tannery refuse, ashes, and liquid are discussed. The first two are rich in lime, the latter is acid. The refuse contains from 0.75 to 2 per cent of nitrogen. The ashes contain in addition to from 30 to 50 per cent lime, from 0.75 to 1.5 per cent potash and 0.5 per cent phosphoric acid. Tannery liquids are of no fertilizing value until neutralized with lime and in some cases allowed to putrefy. Successful practical experiments in the use of refuse and ashes are referred to.

Refuse disposal, Toronto, Ont. (*Engin. News*, 67 (1912), No. 8, pp. 325-328; *Engin. and Contract.*, 37 (1912), Nos. 11, pp. 293-296; 13, pp. 351, 352; 15, pp. 417-419).—This is a condensation of an extended report by R. Hering and J. H. Gregory, and deals with 2 methods of disposal. "(1) the incineration of garbage mixed with other and more combustible refuse, with no utilization of the heat of combustion, and (2) the treatment of garbage alone by the reduction process for the recovery of grease and of tankage for fertilizer base, and with the separate incineration of combustible refuse. The low price at which hydro-electric power is available in Toronto turned the scale in favor of the second alternative. If the salable portions of the combustible refuse were sorted out and sold and only the remainder burned, the estimates indicate a small profit from the combined operations of the reduction works and incinerating plants; otherwise there would be a slight yearly expense."

Analyses of fertilizers, fall season, 1911, B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr.*, 33 (1912), No. 3, pp. 96).—This bulletin contains analyses of fertilizers collected by the fertilizer inspectors of the North Carolina state department of agriculture during the fall of 1911, as well as a list of brands of fertilizers registered for sale during the season 1911-12.

Tabulated analyses of commercial fertilizers, J. TOMLINSON (*Tenn. Dept. Agr. Fert. Bul.* 1911, pp. 50).—Analyses and valuations of fertilizers offered for sale in Tennessee during 1911 are reported. The text of the state fertilizer law and a schedule of current prices of fertilizing materials are also given. It is stated that 68,971 tons of fertilizers were sold in Tennessee during 1911 as compared with 58,612 tons in 1910.

Analyses of licensed commercial fertilizers, 1912, F. W. WOLL (*Wisconsin Sta. Circ. Inform.* 33, pp. 12).—This circular gives a list and guaranties of fertilizers licensed for sale in Wisconsin during the year, analyses of samples submitted by the manufacturers and collected by the station inspectors, and explanations of terms used in statements of analyses of fertilizers and in discussion of the subject of soil fertility.

## AGRICULTURAL BOTANY.

Plant physiology, W. PALLADIN (*Pflanzenphysiologie. Berlin, 1911, pp. VI+310, figs. 180*).—This is a German edition, revised and brought up to date, from the sixth Russian edition of the author's work on plant physiology. It treats extensively of the chemistry of physiological processes.

Preliminary announcements of new findings in germination studies with *Chloris ciliata*, G. GASSNER. (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 10, pp.

708-722).—This is a preliminary account of studies on the influences affecting germination, particularly those of light, and temperature changes in the seed bed. The author states that associated as modifying influences with the light factor are the 3 subfactors of oxygen access (affected by presence or absence of chaff), germinating temperature, and resting period (after maturity).

Seeds were subjected to maximum and minimum constant temperatures and comparisons made with lots in which high and low temperatures were employed for various definite periods. It was found that, while the absence of chaff raised the rate of germination in all cases, a constant high temperature (33 to 34° C.) gave almost a maximum rate of germination and in general the higher rates (94 to 95 per cent) were obtained by the longer periods of exposure (over half the day) to the high temperature. The lowest rate (29 per cent) resulted from exposure of the chaff-covered seeds to the minimum constant temperature (19 to 20°).

Temperature and seed germination, E. LEHMANN (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 8, pp. 577-589).—The author gives a preliminary report of a series of investigations not yet complete on the effects of temperatures and temperature changes on the germination of seeds sensitive to light. The work stands in close relation to that of W. Künzel (*E. S. R.*, 22, p. 720; 26, p. 821). In part the same material was chosen and studied, with the results which were partly different or opposite given in considerable detail.

The effect of heat on seeds in a state of anesthesia, J. APSIT and E. GAIN (*Compt. Rend. Soc. Biol. [Paris]*, 70 (1911), No. 24, pp. 55-58).—In previous publications (*E. S. R.*, 22, pp. 27, 436) the authors showed the action of anesthetics and heat on the diastases of seed. In the present paper a brief account is given of experiments showing the effect of heat and anesthetics on germination.

Different lots of wheat were subjected to ether and ether vapors and then placed in water heated to 58° C. for 5 minutes, and the effect on germination determined. All lots of seed had been previously placed in cold water to bring their moisture content to about 21 per cent. The results show that, other conditions being equal, wheat subjected to anesthetics is much more affected by high temperature than seed not treated with ether. A few minutes' exposure to ether followed by the application of heat was sufficient to destroy the vitality of all the seed. Similar results were obtained with other anesthetics, as chloroform and a solution of cocaine.

If the interval between exposure to ether and placing the seed in hot water was progressively increased, the effect of the anesthetic appeared gradually to diminish and the percentage of germination to increase correspondingly.

The so-called respiration of powdered seeds, L. IWANOFF (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 8, pp. 563-570).—The author reports a continuation of his investigations on carbon dioxide evolution and alcoholic fermentation in seeds (*E. S. R.*, 26, pp. 731, 822), claiming that these support his former conclusions, namely, that the carbon dioxide evolved is largely, if not entirely, of anaerobic origin.

Effect of warm baths on respiration and germination of resting plants, P. P. IRAKLIONOV (*Trudy Imp. S. Peterb. Obshch. Estestvo. (Trav. Soc. Imp. Nat. St. Petersb.)*, 42 (1911), III, No. 2-8, pp. 239-270, figs. 4).—The author sums up the conclusions reached in his investigations substantially as follows:

Warm baths heighten the energy of respiration only during the first few days, after which the respiration curve remains at its normal resting level until it rises on germination. The effects of the warm bath are to be attributed not only to the influence of temperature but also to that of the water. This effect is not a simple and transient stimulation but a complex, deep-lying

process the end result of which is the awakening of the plant. The experiments seem to indicate the activity of enzymes in this connection. It appears that along with oxidation (as evidenced by the carbon dioxide product) several other processes go on, some of them accompanied by evolution of heat.

**Shortening the resting period of shoots by wounding and injection of water,** F. WEBER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 120 (1911), I, No. 3, pp. 179-194, pl. 1).—A report is made in regard to experiments conducted with buds on twigs of several sorts in hothouses, either by merely wounding, or in addition thereto, injecting water at the base of the bud.

It was found that in almost every case injured buds preceded in opening and rapidly outgrew the buds on the same sprouts not so treated. It appeared that the wounding was the most significant factor, but that the injection of water also played a certain rôle in the abnormally early and rapid development.

**The influence of enzymes on the respiration of plants,** S. D. LYOV (*Zv. Imp. Akad. Nauk. (Bull. Acad. Imp. Sci. St. Petersburg)*, 6, ser., 1911, No. 9, pp. 655-678; *abs. in Jour. Chem. Soc. [London]*, 100 (1911), No. 585, 11, p. 641).—The author reports that taka-diastrase exerts a stimulating action on the respiration of living or dead plants of *Vicia faba* and wheat. This action is especially marked with living plants where anaerobiosis initially takes the form of alcoholic fermentation. Merck's diastase produced effects opposite to, and of less magnitude than, those of taka-diastrase.

Emulsin was found to produce the same effects in the boiled and the unboiled condition and to exert a marked retarding action on alcoholic fermentation brought about by hefanol. It exhibited a stimulating influence on the respiration in dead seeds, hence under abnormal conditions, but on the normal respiration of living higher plants it had no effect.

**Further studies on the light requirement of plants in relation to leaf form and position,** J. WIESNER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 120 (1911), I, No. 3, pp. 119-178).—This is a report on a continuation of the author's former studies on light relations of leaves (*E. S. R.*, 23, p. 724), and is a somewhat extended discussion of leaf position as related to light requirement.

Plants with leaves which show no relation of their position to the incidence of light are here called aphotometric. Other plants assume positions which are favorable to light incidence or to protection for oversupply. These positions may become fixed, as in the case of the compass plants, etc.

The results of studies made on several plants are given in some detail.

**The relation of light and temperature to leaf fall,** O. VARGA (*Österr. Bot. Ztschr.*, 61 (1911), No. 2-3, pp. 74-88; *abs. in Magyar Bot. Lapok [Budapest]*, 10 (1911), No. 11-12, pp. 448, 449).—The author reports a direct relation between a lack of light and a low temperature and leaf fall of plants through the influence which these factors have in diminishing transpiration and assimilation. A reduction of light or temperature appears to act through the assimilation and transpiration of the plant, stimulating the formation of the absciss-layer at the bases of the petioles and resulting in the fall of the leaves.

**Studies on cessation of flowering,** H. WACKER (*Jahrb. Wiss. Bot. [Pringsheim]*, 49 (1911), No. 4, pp. 522-578, pls. 3, figs. 5; *abs. in Ztschr. Bot.*, 4 (1912), No. 2, pp. 133, 134).—This is a comparative study of the various phenomena accompanying this change in case of many flowers.

**Opening and closure of stomata as shown by the method of infiltration,** H. MOLISCH (*Ztschr. Bot.*, 4 (1912), No. 2, pp. 106-122, figs. 2).—A new method of demonstrating the closure or degree of opening of stomata is described, which

consists essentially in placing upon the under surface of the leaf a small portion of a certain liquid and observing the rate of its infiltration as evidenced by its forming in that part of the leaf a spot which, by transmitted light, is translucent.

For this purpose it is stated that water will not answer, but alcohol is found suitable, while benzol, xylol, and oil of turpentine are very much more sensitive indicators in most cases. With a decrease of the openings, filtration diminishes. At a certain point alcohol, it is claimed, ceases to pass, while the other liquids continue to enter, thus distinguishing between very small degrees of opening and absolute closure. Detailed and tabulated findings are given of a great number of studies carried on with many different plants. Stomata in fresh leaves were nearly always found to be open on sunny days, but nearly or entirely closed at night. In case of wilted and dried leaves the stomata were usually almost or quite closed, in many cases even to benzol.

Several advantages are claimed for this method over others now in use, some of which are here discussed, as are also the results obtained by their employment.

A new method of estimating the aperture of stomata, F. DARWIN and D. F. M. PERTZ (*Proc. Roy. Soc. [London], Ser. B, 84 (1911), No. B 569, pp. 136-154, figs. 10; abs. in Ztschr. Bot., 4 (1912), No. 2, pp. 142, 143*).—The estimate of stomatal aperture obtained by this method (called the porometer method) is based upon the amount of air drawn through a funnel tube, glued to the stomatal surface of the leaf, as shown by a column of water in the stem of an attached and partly exhausted T-tube. The air is drawn through the stomata outside the glass funnel, through the leaf tissue, and again through the stomata inside, its amount and variations being measured by means of the fall of the water column in the stem of the T-tube. The merits claimed for the method are that (1) the results obtained are independent of transpiration and (2) the living, uninjured stomata can be studied continuously for hours or days together.

Among the results given of studies already made by this method, it is claimed to have been shown that in case of leaves severed from the plant the first effect of withering is the opening of the stomata, followed, however, by their closure. Publication of other results is also promised.

Transpiration in wet leaves, V. S. ILIN (*Trudy Imp. S. Peierb. Obshch. Estestvo. (Trav. Soc. Imp. Nat. St. Petersb.), 42 (1911), III, No. 2-8, pp. 359-414, figs. 23*).—This is an account of a series of experiments on the transpiration and related phenomena in leaves soaked in water or in solutions of salts.

It was found that when the stomata are open naturally transpiration in wet plants is always heightened and that such plants desiccate rapidly, the curve of transpiration approximating that shown by plants in the damp atmosphere of dewy mornings. If compelled to open their stomata, however, by immersion in potassium nitrate solution, the plants show no increase in transpiration or in rapidity of desiccation. No such increase of transpiration follows the wetting of plants the stomata of which are closed, except a slight increase observable after long immersion in case of plants having thin cuticle. Immersion tends to cause closure of the stomata, but this tendency is opposed by light. Some leaves lost up to 43 per cent of their weight before their stomata were found to be closed. Transpiration curves showed interrupted variations which bear a certain relation to the curves of water absorption by the leaves.

Transpiration and the ascent of sap, H. H. DIXON (*Ann. Rpt. Smithsn. Inst. 1910, pp. 407-425, figs. 4*).—A summary is given of evidence that is held to support the author's cohesion theory of the ascent of sap in plants (*E. S. R., 18, p. 825; 21, p. 725*).

**Measuring the transpiration of emersed water plants, C. H. OTIS** (*Rpt. Mich. Acad. Sci.*, 13 (1911), pp. 250-253, pls. 2).—A description is given of a form of tank devised by the author for measuring the evaporation of emersed water plants.

It was found that unsubmerged water plants transpire large quantities of water, and that this takes place principally during the day time. In the case of the one exception, the water lily, the presence of the plants in the tanks materially retarded evaporation from the free water surface.

**The relative wilting coefficients for different plants, L. J. BRIGGS and H. L. SHANTZ** (*Bot. Gaz.*, 53 (1912), No. 3, pp. 229-235).—Observations have been made of a considerable number of plants growing in different types of soil to determine their wilting coefficient (*E. S. R.*, 26, p. 822). These included cereals, grasses, and wild plants from semiarid and arid regions, and the results obtained led the authors to conclude that the variation exhibited in the wilting coefficient of different plants is much less than has hitherto been supposed and that it is insignificant compared with the range in moisture retentiveness exhibited by different soils.

Only slight differences were found to exist among the various crops in their ability to reduce soil moisture content before wilting occurs. Sorghum, millet, wheat, oats, barley, and the grasses are practically the same. Rye and rice appear a little lower than the mean, and corn and the legumes slightly higher.

**Conditions which affect the branching of roots, LULU M. NEWLON** (*Rpt. Mich. Acad. Sci.*, 13 (1911), p. 200).—Observations were made on a number of species of plants to determine the factors which influence the branching of roots. It is a well-known fact that when roots are injured at their tips they produce lateral rootlets, but the experiments, in which about 1 dozen species of plants were used, indicate that contact does not act as a stimulus for the production of lateral roots. In most of the plants lateral roots were freely produced in the soil. In some aquatic and semiaquatic plants light inhibited the growth of the roots, while in the terrestrial plants, when the roots were under water, the lateral branching took place with equal freedom in light and in darkness.

**Agricultural microbiology, E. KAYSER** (*Microbiologie Agricole. Paris, 1910, 2. ed., rev. and enl., pp. 481, figs. 95*).—This is a revised and enlarged edition of a work previously noted (*E. S. R.*, 17, p. 849).

**Soil fungi, H. N. GODDARD** (*Rpt. Mich. Acad. Sci.*, 13 (1911), pp. 208-214).—A preliminary report is given of fungi found in soils, which indicates an abundant fungus flora which is conspicuous, rather uniformly distributed, and constant in different soils. Tillage and manuring, so far as observations have gone, seem to produce little change in the species and number of individuals present. Many of the fungi show variability in their structural characters when cultivated on media of constant composition. One form, which showed the structural characters of *Fusarium* and *Cephalosporium*, is thought to be the probable cause of a wilt disease which attacks several species of garden plants, including asters, sweet peas, zinnias, and *Salvia splendens*.

**The occurrence of *Zygorhynchus moelleri* in Michigan, H. GROSSMAN** (*Rpt. Mich. Acad. Sci.*, 13 (1911), pp. 204-207, figs. 2).—The author reports the discovery in soil samples of *Z. moelleri*, a rather common soil fungus of Europe.

**Formation of volatile acids after fermentation, A. OSTERWALDER** (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 20-25, pp. 481-498).—The author studied the after growth of several yeasts in fruit and grape juices with reference to the simultaneous production of volatile acids, with findings substantially as follows:

After the cessation of fermentation by pure yeast a new and often luxuriant growth appears, showing as flocculent or glistening layers of new yeast on or near the bottom. Under the same circumstances and at the same time at from 20 to 22° C. in 4 or 5 months a volatile acid, said to be acetic, forms to the amount of about 0.18 per cent. This apparently depends not upon the presence of unfermented sugar or upon the simple oxidation of alcohol but upon the presence of certain kinds of yeast. The author thinks it possible, however, that these yeasts are able by means of oxidases to oxidize alcohol to this acid.

A new fermenting fungus, A. OSTERWALDER (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 11-14, pp. 257-272, pl. 1, figs. 2).—Continuing the above studies, the author reports that he has discovered, isolated, and cultivated an actively fermenting fungus said to be new and by him named *Monilia vini*, in regard to which the following particulars may be noted:

*M. vini*, isolated from an acid apple wine, proves to be the most active in producing fermentation of all the *Monilia* forms, completely fermenting fruit and grape wine, this change occurring most rapidly with free access of air. The new species is able to develop rapidly in as strong a solution as 1.2 per cent of malic acid, also to ferment sugar in 0.4 per cent of alcohol, giving as a result of such fermentation both volatile and nonvolatile acids along with alcohol. It appears able to ferment any sugar remaining after the cessation of ordinary vinous fermentation, to the advantage of the wine, showing no injurious effects. It seems to ferment most rapidly dextrose and levulose; less rapidly saccharose, lactose, and galactose; and least rapidly maltose. In fermentation of the last of these and the first two the fungus develops much volatile acid.

Biological characteristics are described at some length.

The mycorrhiza of *Solanum*, N. BERNARD (*Ann. Sci. Nat. Bot.*, 9. ser., 14 (1911), No. 4-6, pp. 235-258, figs. 12; abs. in *Bot. Gaz.*, 53 (1912), No. 3, p. 271).—In continuation of investigations on the association of fungi with the formation of tubers in certain plants (*E. S. R.*, 14, p. 635), the author had begun a study of tuber formation in *Solanum*, but the work was stopped by his death. In the paper presented some account of his investigations is given. He had found that *S. dulcamara* and *S. maglia* when grown under normal conditions had their roots infested with fungi, but that when grown in gardens *S. maglia* did not show any mycorrhiza. The results obtained are believed to be suggestive of tuber formation in the potato in a wild state.

*Gastrodia elata* and its symbiotic association with *Armillaria mellea*, S. KUSANO (*Jour. Col. Agr. Imp. Univ. Tokyo*, 4 (1911), No. 1, pp. 1-66, pls. 5, fig. 1).—According to the author, *G. elata* is a nonchlorophyllous orchid which is unable to exist as an autophyte. The vegetative organ of the plant is represented simply by a tuberous rhizome. It forms mycorrhiza with the mycelium of *A. mellea*, or, as it is often called, *Rhizomorpha subterranca*. Tubercles cultivated in pots with sand, loam, or humus soil produced numerous offshoots, but none of them ever reached the flowering stage. The saprophytic development of the fungus reduces the vegetative organs of the orchid, and flowering stalks are produced. It was found that only when the mother tuber contains mycorrhiza does it develop a full-grown offset, which remains dormant during the winter and develops the inflorescence axis the spring of the next year.

The fungicidal action of bulbs of orchids, N. BERNARD (*Ann. Sci. Nat. Bot.*, 9. ser., 14 (1911), No. 4-6, pp. 221-234, figs. 3; abs. in *Bot. Gaz.*, 53 (1912), No. 3, pp. 267, 268).—The fact that certain orchid bulbs have been found free from fungi while the roots contained mycorrhiza led the author to a study of the phenomenon of the fungus not passing from the roots to the succulent bulbs.

Fragments of bulbs were placed in tubes containing cultures of fungi isolated from various orchids. The growth was inhibited wherever the fungus came in contact with the fluids given off from the bulbous material.

The conclusion is reached that the bulbs from some orchids contain a substance of a fungicidal nature that may be considered comparable to a diastase. It is readily diffusible and is destroyed at a temperature of 55° C. The action is considered specific and is held to confirm the hypothesis of the author regarding the symbiosis with mycorrhizal fungi, while protecting the main body of the plant against invasion (E. S. R., 22, p. 722).

**Effects of Roentgen rays on micro-organisms and ferments, H. GÜNTHER** (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens, 1910, No. 1, Sect. B, pp. 11, 12; abs. in Bot. Centbl., 116 (1911), No. 24, p. 614*).—A brief note reviewing the literature on this subject, most of which is declared to show negative results.

**Nitrogen-fixing bacteria in leaves of Rubiaceæ, F. C. VON FABER** (*Adv. print from Bul. Dépt. Agr. Indes Néerland., 1911, No. 46, pp. 3*).—The author presents a preliminary report of investigations in progress, from which he is able to give results and conclusions in substance as follows:

The plants of this group bearing these bacteria may be outwardly known by peculiar knotty thickenings of the leaves filled with bacteria. Garden species so affected are *Pareta indica*, *P. lanceolata*, *P. angustifolia*, *P. zimmermanniana*, and *Psychotria bacteriophila*. Bacteria are found in the growing points and from there supposedly extend with the growth of the plant, being found in the buds, flowers, fruit, and seeds. In the young bud leaves the stomata open abnormally early and the massed bacteria press into the leaf interior, loosening the cellular structure and causing characteristic cytological changes which result in the production of a characteristic bacterial tissue. In this a considerable number of starch grains appear, supposedly to serve nutritive purposes for the bacteria.

Already bacteria have been isolated by culture from *P. indica* and *Psychotria bacteriophila*, one species only from each. The bacteria of Rubiaceæ seem to show great similarity among themselves and may be adapted forms of one original species. The author thinks that these bacteria play the important rôle in the life of the plants in which they live of fixing atmospheric nitrogen, and claims that this conclusion is supported by the experimental evidence thus far obtained. This work of fixation is thought to be limited to the bacterial leaf galls where the bacteria are present in largest numbers and where the nitrogen is present mainly in the form of protein.

**Nitrogen fixation by fungi in relation to nitrogen nourishment, G. STAHEL** (*Jahrb. Wiss. Bot. [Pringsheim], 49 (1911), No. 4, pp. 579-615; abs. in Bot. Centbl., 119 (1912), No. 1, pp. 9, 10*).—These experiments were undertaken for the purpose of finding, if possible, new cases of nitrogen fixation by fungi and of studying the relation of nitrogen assimilation to nitrogen content in their food supply.

The organisms belonged for the most part to the so-called imperfect fungi, 54 species being investigated. In case of a nutrient solution containing 0.0001 per cent of nitrogen, it was found possible to divide the fungi into groups, the first of which, containing 25 species, showed no growth but much oil and was entirely sterile; the second, comprising 22 species, showed better but slight growth and considerable oil, and was almost or quite sterile; a third group of 5 species showed relatively good growth, very good fruiting, and but little oil. Of the 9 species which showed nitrogen fixation 4, it is claimed, had not before been credited with that power. These are *Botrytis cinerea*, *Bispora molinioides*, *Epicoccum purpurascens*, and *Melanomma* sp. Three fungi were found to contain nitrogen as compared with the amount in the nutrient solution in the ratio of 1:1, while one showed a ratio of 1:4. These ratios, it is stated, tend to rise with an increase of nitrogen content in the substratum.

Nitrogen assimilation and a new hypothesis of the first stages of protein formation, O. BAUDISCH (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 20-25, pp. 520-540).—Continuing previous work (E. S. R., 25, p. 435) the author presents in detail his further studies regarding the steps and agencies in nitrogen assimilation and his hypothesis of a photo-chemical agency in connection therewith. He claims that these studies show results confirmatory of the hypothesis.

Protein synthesis in lower plants, K. PURIEWITSCH (*Biochem. Ztschr.*, 38 (1912), No. 1-2, pp. 1-13).—This is an investigation of the relative availability of different nitrogen compounds for the synthesis of protein. Proceeding upon the assumptions (1) that such synthesis may be judged with a degree of accuracy from the amount of carbon dioxide produced, as a measure of the energy required in the oxidation of the nitrogen compounds, and (2) that the less available require the more energy, the author cultivated *Aspergillus niger* on a suitable substratum in numerous experiments, employing different compounds of nitrogen as nitrogen sources. The weight of carbon dioxide evolved in each experiment was compared with the dry weight of mycelium so employed and the ratios so found were then compared.

The results obtained are said to show that the employment of energy in protein synthesis is least when the amino acids are used as sources of nitrogen. In case of ammonia salts, and particularly of the nitrate, it is considerably greater. From this fact (supported by other observations and inferences) the author concludes that the amino acids are the best sources of nitrogen for protein synthesis.

A physiological study of nitrate-reducing bacteria, E. B. FRED (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 13-19, pp. 421-449 pls. 6, figs. 9).—Details are given of an extended investigation of 4 bacteria, *Bacillus fluorescens liquefaciens*, *B. pyocyaneus*, *B. denitrificans*, and *Bacterium hartlebi*, in regard to their reducing activity as influenced by such factors as energy supply, presence of nitrites and indicators, and occurrence of certain reactions.

Potash requirement by the nitrogen bacteria, I. VOGEL (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 13-19, pp. 411-421).—This is a resumption of work previously undertaken by the author in connection with M. Gerlach (E. S. R., 15, p. 449). It is claimed that the results of the experiments now reported confirm the conclusions resulting from the earlier series, namely, that a certain development of the bacteria and nitrogen fixation may occur in the absence of potash compounds from the nutrient solution, but that the intensity, both of growth and of nitrogen assimilation, is greatly increased by its presence in suitable quantity.

Ammonia and nitrates as a nitrogen source for mold fungi, G. E. RITTER (*Ber. Deut. Bot. Gesell.*, 29 (1911), No. 8, pp. 570-577).—In continuation of a previous study (E. S. R., 22, p. 724), investigations were carried out with *Cladosporium herbarum*, *Mucor racemosus*, and *M. spinosus*, as a result of which the author claims that the nitrate-assimilating fungi are quite commonly able under suitable conditions (in neutral or alkaline culture solutions) to reduce nitrates to nitrites as a first step in such assimilation. This view is held to be supported by the observation that the nitrites can also be utilized as a source of nitrogen.

Anaerobic decomposition of protein and intramolecular respiration in plants, E. GODLEWSKI (*Bul. Internat. Acad. Sci. Cracovie, Cl. Sci. Math. et Nat., Ser. B*, 1911, Nos. 8, pp. 623-704, fig. 1; 9, pp. 705-717).—Attempts were made to determine by experiments with seeds of white and of blue lupines in air-free containers the relation of dependence, if any, which exists between these two processes. The conclusions drawn by the investigator from the final analyses are briefly as follows:

Anaerobic decomposition of protein in seeds of lupines in water or a sugar solution is entirely independent of the intensity of their intramolecular respiration. Both these processes are affected by the dissolved sugar, however, which decreases the former, but increases the latter process. The former, moreover, goes on long after the latter has ceased, even after the seeds have been killed by suffocation.

It follows, according to the author, that anaerobic decomposition of protein in lupines is an enzymatic process. In the early stages of the experiments albumose and peptones were broken down; later the more complex proteids. In the living seeds the protein decomposition appears to be proportional to the time of its duration; after their death, to the square root of the time. Intramolecular respiration in the glucose solution appears to go on in the lupine seeds alike whether resting or sprouted, which fact is taken to indicate that no new synthesis of zymase occurs during germination; but in water alone this process is at first much more rapid in the sprouted seeds, which phenomenon is attributed to the hydrolysis of the reserve material in the seeds and not to increase of zymase. Pepsin is also supposed to form during germination. Citric acid added to the solutions was not utilized in intramolecular respiration, but appears to decrease it and to shorten its period.

**The nutrition of some epiphytic Bromeliaceæ, C. PICADO** (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), No. 9, pp. 697-699*).—As the result of a study of a number of species of epiphytic bromelias, the author claims that they absorb not only their mineral, but also their proteid and other substances from the vegetable and animal detritus held by their leaves. It is possible that these are the only plants the nutrition of which depends entirely upon the detritus collected in the depressions at the base of the leaves.

**On the origin of carbon assimilated by plants, L. CAILLETET** (*Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 19, pp. 1215-1217; abs. in Bot. Centbl., 119 (1912), No. 2, p. 35*).—Studies on *Adiantum*, *Aspidistra*, and other plants habitually growing in rather dense shade are reported, in which it is shown that their photosynthesis was not sufficient to account for the carbon present in their structures. Experiments showed that these plants obtained a part of their carbon from the soil, indicating that they have two sources of carbon, the carbon dioxide of the air and the organic compounds of the soil.

**Chlorophyll in plants and colloidal chlorophyll, A. HERLITZKA** (*Biochem. Ztschr., 38 (1912), No. 3-4, pp. 321-330*).—The author has attributed the displacement of the absorption bands in spectra of living leaves toward the red end (as compared with those of solutions of chlorophyll in alcohol, etc.) to the supposedly colloidal condition of chlorophyll in a gelatinous solvent, and this is a study of colloidal solutions of chlorophyll prepared from spinach, carried out with the aim of throwing light on the condition of chlorophyll as it exists in living plants.

He concludes that in expressed leaf sap the chlorophyll is held in a different state from that in case of ordinary solutions, and asserts that it is the same as in colloidal chlorophyll solutions. This colloidal solution shows the presence of a dispersoid, while it is still a question whether this may be said of a solution of chlorophyll in alcohol or acetone. Such colloidal chlorophyll is stated to be an electronegative colloid, unstable and easily forming a flocculent precipitate. The difference between the spectrum of chlorophyll dissolved in alcohol and that of the chlorophyll in leaves, expressed sap, etc., is declared to be attributable to the fact that in the latter case the chlorophyll is in the colloidal state not as a genuine colloid, but as a dispersoid. The identity of the chlorophyll in leaves with that in colloidal solutions is admittedly not yet fully established.

Studies on anthocyanin, III, V. GRAFE (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 120 (1911), I, No. 6, pp. 765-810, figs. 2*).—In studies on the coloring matter of Pelargonium, the author was able to separate the material studied into two main parts, one, deep yellowish-red and crystallizable, the other, brown-red, drying to an amorphous mass. He considers the latter probably a decomposition product of the former. Further particulars of a microscopic and chemical study and of their relations to known compounds are given.

Investigations on the origin of alkaloids in plants, G. CIAMICIAN and C. RAVENNA (*Ann. Chim. et Phys., 8. ser., 25 (1912), Mar., pp. 404-421*).—Experiments were made by inoculating tobacco and *Datura*, plants which contain known alkaloids, with solutions of various nitrogenous and nonnitrogenous compounds. The experiments are not considered extensive enough to demonstrate the origin of the alkaloids, but they are thought to indicate that the amido acids play an important part in their synthesis. In general, pyridin and ammonia exerted little influence in increasing the total alkaloids, while the injection of asparagin resulted in a great increase. Glucose increased the nicotin content of tobacco plants, while phthalic acid reduced the alkaloid content.

In connection with these investigations it was found that the alkaloids increased in the check plants that were simply wounded without the injection of any substance.

The tannin-colloid complexes in the fruit of the persimmon, F. E. LLOYD (*Biochem. Bul., 1 (1911), No. 1, pp. 7-41, pls. 3*).—From further studies on tannin in fruits (E. S. R., 25, p. 28), it is concluded that the explanations heretofore given concerning the fate of tannin during the process of ripening in the date and the persimmon are inadequate. The author claims that tannin as such is not insoluble, but that it has in large part combined with an associated colloid to form an insoluble colloidal complex. Evidence for this has been found in the behavior of the tannin-mass in relation to free tannin and chemical reagents. The tannin-mass is claimed to have an internal structure, consisting of a system or complex of canals, spaces, etc., which have a definite existence. Their behavior during the maturing of the tannin cell and their forms are described in considerable detail. The material called the tannin-mass is a tannin-colloid complex, the second portion of which appears to be a cellulose mucilage. During the course of ripening of the fruit the amount of free or soluble tannin is reduced, and as long as any is present it may escape from the tannin-mass. The view is advanced that during ripening the supposed cellulose mucilage increases in quantity and that eventually sufficient forms to engage most of the tannin.

Influence of iron on the growth of certain molds, B. SAUTON (*Ann. Inst. Pasteur, 25 (1911), No. 12, pp. 922-928; abs. in Rev. Sci. [Paris], 50 (1912), I, No. 11, pp. 336, 337*).—A study was made of a number of species of *Aspergillus*, *Penicillium*, *Mucor*, *Rhizopus*, and *Racodium* grown in Raulin fluid in the absence of any iron salt. *Aspergillus* and *Penicillium* did not increase in weight to any appreciable extent, while the other fungi seemed to be able to grow in the absence of iron.

It is observed that the simultaneous presence of iron and oxygen seems essential for the formation of spores; they always appeared in the parts of the culture which had the greatest access to the air. Spore formation seems to be accompanied with the fixation of oxygen, and this is probably brought about through the action of the iron.

The extraordinary sensitiveness of *Aspergillus niger* to manganese, G. BERTRAND (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), No. 9, pp. 616-618*).—

The author shows that *A. niger* is sensitive to 1 part in 10,000,000,000 of manganese. On account of this great sensitiveness the author calls attention to the necessity for the use of chemically-pure substances in culture media. The ordinary iron sulphate of commerce is said to contain from 0.2 to 0.5 part in 1,000 of manganese.

**The poisonous action of oxalic acid salts and the physiological action of calcium.** O. LOEW (*Biochem. Ztschr.*, 38 (1912), No. 3-4, pp. 226-243).—As a result of this extension of his former investigations, now made on seeds, shoots, and roots of several cultivated plants, on the leaves of aquatic plants, and on various algae and fungi, as well as lower water animals, the author announces that potassium oxalate exerts a poisonous influence upon the most diverse plant forms (exclusive of the lowest algae and fungi which also require no calcium). A relation is argued between the physiological significance of calcium compounds and the injurious effects of oxalates. Observations show that the injurious reaction of the latter manifests itself in the cell nucleus and the chloroplasts, from which he infers the presence of a compound of calcium in such vegetable cells (as in lower animal cells which exhibit physiological analogies in this respect).

**Effects of basic compounds on seedlings and on the lower organisms,** T. BOKORNY (*Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 20-25, pp. 537-605).—The author, in pursuance of previous studies (E. S. R., 25, p. 433), investigated the influence of various dilute basic compounds on the development of seedlings and of micro-organisms. It was found that, while solutions of 0.01 to 0.25 per cent prevented or retarded development in case of nearly all compounds studied, ammonium chlorid exerted the most deleterious effect, and that such effect was noticeable in the very lowest concentrations of this salt tested.

**Movement of minerals in autumn leaves,** E. RAMANN (*Landw. Vers. Stat.*, 76 (1912), No. 3-6, pp. 157-164).—The author's analyses, at suitable intervals, of leaves of beech, oak, hazel, and birch, led him to conclude (1) that, in the normal dying of leaves in autumn, there is a considerable movement of proteins from the leaves to the stem; (2) that the movement of potassium and the movement in considerable quantity of phosphoric acid in the same direction seems to be influenced by the nourishment of the stem; (3) that lime and silica about double in quantity in the leaves before death; (4) that these transfers take place during the short period of yellowing and dying; and (5) that these exchanges are more significant in the life of the plant than has commonly been held by investigators.

**Mineral movements on freezing of leaves,** E. RAMANN (*Landw. Vers. Stat.*, 76 (1912), No. 3-6, pp. 165-167).—Continuing the above studies, the author reports upon the effects of freezing the leaves of oak, pine, and fir on the translocation of mineral substances. The partial freezing of the foliage, October 18, 1909, made it possible to compare not only injured and uninjured leaves of the same tree but also frozen and unfrozen parts of the same leaves.

As a result of his comparative analyses of the ashes of leaves taken while living and of frosted leaves, he reports (1) that both the protein and the sulphur contents of the leaves remained unchanged on freezing; (2) that potassium and phosphoric acid were considerably decreased; (3) that calcium was added in large quantity as in regular autumn dying of leaves; and (4) that these changes occurred in the very short interval between thawing and drying out, which fact is pointed to as an illustration of the possibilities of rapid transportation in dying or dead leaves.

**Smoke, fumes, and cultivated soil** (*Rev. Sci. [Paris]*, 50 (1912), I, No. 10, pp. 311, 312).—Brief reference is made to investigations by Wieler on the

injurious effect of smoke and factory fumes on soil and vegetation in the region of Aix-la-Chapelle.

It was found that the factory fumes contained sulphuric, sulphurous, and hydrochloric acids, which dissolved the lime of the soil and thus rendered the soil increasingly acid and interfered with the bacterial activity of the soil, particularly nitrification. Liming corrected this condition and prevented destruction of plant growth in case of forest trees. The chestnut appeared to be one of the most resistant trees to acid fumes. In addition to the harmful effect on the soil, the fumes occasionally caused direct injury by corrosion and by deposit of soot on the leaves.

**Premature fall of flower petals, H. FITTING** (*Jahrb. Wiss. Bot. [Pringsheim]*, 49 (1911), No. 2, pp. 187-263, figs. 3; *abs. in Ztschr. Bot.*, 4 (1912), No. 2, pp. 131-133).—This is a detailed account of the author's study of the casting of fresh and even of very young petals of *Geranium pyrenaicum* and several other plants found to be highly sensitive to certain influences unfavorable in this respect. Among these influences are gases and vapors in the atmosphere, particularly illuminating gas, carbon dioxide, tobacco smoke, chloroform, ether, and hydrochloric acid; high temperature, agitation, and dryness; and wounding of the petals.

Some very sensitive plants showed reaction to the unfavorable stimuli within a few seconds. The fall of the petals occurred after periods varying from a few minutes to several hours. Further studies are contemplated. A bibliography is appended.

**Bud mutations of *Solanum maglia*, E. HECKEL** (*Compt. Rend. Acad. Sci. [Paris]*, 153 (1911), No. 7, pp. 417-420).—In continuation of a previous note (E. S. R., 20, p. 733), an account is given of a bud mutation of *S. maglia* produced by heavy manuring in conjunction with the use of artificial fertilizers.

In 1910 the author obtained 5.5 kg. of tubers of the mutating form, most of which were of a reddish violet color. These tubers were planted in April, 1911, and produced a considerable crop, many of the individual tubers weighing from 350 to 380 gm. and some of the hills yielding as much as 2 kg. The plants appeared completely free from fungus diseases.

Attention is called to some of the variations which have apparently become fixed in this form, and the author notes the occurrence of violet colored tubers both in this species and in *S. commersonii*. This is thought to indicate that the contention that the Giant Blue, a well-known variety of *S. tuberosum*, is the same as the mutant of Labergerie is not correct.

**A study of hybrids between *Nicotiana bigelovii* and *N. quadrivalvis*, E. M. EAST** (*Bot. Gaz.*, 53 (1912), No. 3, pp. 243-248, figs. 4).—Studies of these species of *Nicotiana* have been carried through several generations, and the author has discovered 2 elementary species of *N. bigelovii*. In one the capsules are 2-celled and selection of individuals has not increased the number, while in the other species there is a tendency to more than 2 cells in the capsule, which tendency is always transmitted.

The author believes that the species *N. quadrivalvis* and normal *N. bigelovii* are alike in all specific characters except the number of cells, and since they give fertile hybrids it is proposed that the first species should be considered a variety, its name being *N. bigelovii quadrivalvis*.

**A retrogressive metamorphosis artificially produced, S. ALEXANDER** (*Rpt. Mich. Acad. Sci.*, 13 (1911), p. 198).—The author states that occasionally matured flowering buds of the peach inserted in a stock by bud grafting will develop, in which case the peduncle increases to a length of 5 or 6 in., the sepals grow to the size and length of full-sized leaves, and the petals and stamens are

also greatly modified. If these flowers are permitted to develop further they will send out buds which will ultimately grow into a branch.

The influence of the seed upon the size of the fruit in *Staphylea*. I. J. A. HARRIS (*Bot. Gaz.*, 53 (1912), No. 3, pp. 204-218, figs. 4).—The author has found that the length of the fruit and the number of ovules formed, as well as the seeds developing, are interdependent, and often very closely so. The correlation for length and number of seeds per locule is higher than that for length and number of ovules per locule. These two facts taken in conjunction indicate a physiological relationship between the length of the fruit and the number of seeds developing.

### FIELD CROPS.

The relation of electricity to vegetation and agricultural products. A. BRUTTINI (*Azione dell' elettricità sulla vegetazione e sui prodotti delle industrie agrarie*. Milan, 1912, pp. XVI+459; rev. in *Agr. Mod.*, 18 (1912), No. 5, p. 73).—This work is divided into 4 parts, the first of which deals with atmospheric electricity, and the second with ancient and modern observations of the rôle of electricity in plant physiology. The third part deals with the effect of electricity on the germination of seeds and the development of plants, proceeding in chronological order from 1746 to 1911, and states the results of some hitherto unpublished experiments. The fourth part presents the results of studies of the effects of X-rays on the causes of fermentation in must, wine, vinegar, alcohol, butter, milk, eggs, and other agricultural products.

Electroculture at Halle. J. KÜHN (*Ber. Physiol. Lab. u. Vers. Anst. Landw. Inst. Halle*, 1911, No. 20, pp. 219-227).—The author quotes some results obtained by Lodge and cites experiments conducted by Breslau at Kryschanowitz in 1903, in which electrical influence apparently increased the yield of strawberries 128 per cent, of sugar beets from 120 to about 140 per cent, and of barley and beans about 32 per cent.

In some of the author's experiments one-third of each plat of a fertilizer test with clover was influenced by electricity, one-third left uninfluenced, and the middle third used as a buffer. The middle third excelled either of the others, and the electrified third gave somewhat the lowest average hay yields.

In the remainder of his experiments the fertilizer plats were divided into only 2 parts. Unelectrified and nonirrigated rye averaged 6.6 per cent more straw and 11.2 per cent more grain than the electrified portions of the plats. There were apparently slight increases of potato yields on the electrified portions of plats except under irrigation, where the unelectrified crop produced a markedly heavier yield with a somewhat lower starch percentage. In case of mangels the electrified crop gave 9.96 per cent more roots and 8.66 per cent more leaves than the unelectrified crop, while electrified sugar beets gave considerably higher yields of roots which also stood somewhat higher in sugar percentage on both irrigated and nonirrigated plats. Under irrigation, barley, rye, winter wheat, and summer wheat gave about the same grain and straw yields whether electrified or not.

The influence of root development on the tillering power of cereals, A. E. PARR (*Agr. Jour. India*, 7 (1912), No. 1, pp. 73-78).—The author states briefly some results obtained by planting cereals in accordance with the Demtschinsky and Zehetmayr methods. The Demtschinsky method, as described, consists of transplanting young plants in such a way as to leave them from 1½ to 2 in. deeper in the ground. This leaves the lowest nodes beneath the surface and causes the development of adventitious roots. Yields of 8,000 lbs. of rye and an initial saving of 75 per cent of the seed usually required are claimed for

this method. The Zehetmayr modification of this system consists of sowing in furrows which are later filled in around the plants instead of transplanting.

Although the author's work with wheat in India along these lines was destroyed by ants, he says that corn planted in furrows about 5 in. deep gave about  $1\frac{2}{3}$  times as great yields as that sown on the level.

Earthing up was also tested for somewhat similar purposes, but gave lower results than deep transplantation.

**The Demtschinsky hilling method**, N. DEMTSCHINSKY (*Deut. Landw. Presse*, 38 (1911), No. 25, p. 293, fig. 1).—The author outlines the Chinese method of hilling small grains for moisture conservation and the development of the root system. He recommends an implement manufactured in Magdeburg with which a man and horse can hill from 6 to 7 hectares (14.82 to 17.29 acres) of grain per day.

**Insuring increased yields—the theory and practice of the Demtschinsky methods for growing small grains**, N. A. and B. N. DEMTSCHINSKY (*Die Verrielfachung und Sicherstellung der Ernteeerträge, Theorie und Praxis der Ackerbaekultur*. Berlin, 1909, pp. 116, pls. 12, figs. 10).—A discussion of the theory underlying the authors' new methods is followed by directions for their use in grain growing and a statement of the results of tests and observations at Torbino and of other tests of transplanting and hilling methods.

**[Tests of the Demtschinsky method]**, G. BOHUTIGNSKY (*Illus. Landw. Ztg.*, 31 (1911), Nos. 3, pp. 13, 14; 5, pp. 29–31, figs. 3).—The author summarizes the results of experiments with winter wheat, winter barley, and oats conducted in 1909–10. Tables state in detail the results obtained by the ordinary method, and the deep sowing, hilling, and Zehetmayr modifications of the Demtschinsky method.

From the data presented the author concludes that hilling produces a greater production per plant which may compensate for the loss due to thinner seeding. The use of the Demtschinsky method prolonged the vegetation period by from 3 to 8 days, but increased the danger from rust. The new methods gave a higher yield per plant but not per acre than the ordinary method. The deep planting method gave negative results.

**Tests of the new grain cultural methods of Demtschinsky and Zehetmayr**, O. LEMMERMANN ET AL. (*Landw. Jahrb.*, 41 (1911), No. 2, pp. 163–256).—These tests were conducted at Hohenheim on the experiment fields of the Royal Agricultural High School of Württemberg. The author states in tables the results obtained since 1908 in work with winter rye, barley, wheat, and oats, as well as with some summer varieties.

From the data presented he concludes that thin sowing resulted in unusual tillering, but no marked difference appeared in the tillering of grains that were hilled or planted more deeply than usual. The use of the Zehetmayr method resulted in tillering about midway between that following the Demtschinsky and the ordinary methods. Tillering was most affected in case of winter barley, less so in case of winter rye and winter wheat, and least of all in case of summer barley.

Both methods apparently retarded ripening by from 3 to 10 days. The Demtschinsky method resulted in a greater retardation than did the Zehetmayr, but if the plants were more deeply set later a more regular development of the straw, and therefore a more regular ripening of the grain, was attained than if this work were left undone. The Demtschinsky method more effectively prevented lodging, the Zehetmayr method accomplishing this to a lesser degree.

The grain and straw yields per plant were effectively raised by the Demtschinsky method as compared with the ordinary method, especially in case of winter barley. The Zehetmayr method gave results midway between. The

Demtschinsky method gave lower yields when hilling and transplanting were resorted to than when they were omitted. The Demtschinsky method and to a less degree the Zehetmayr method increased the percentage of grain, the 1,000-kernel weight, and the size of kernel. All things considered, the author believes that on the heavy clay soil used in the test only the Zehetmayr method compared favorably with carefully conducted drilled seeding by the older method. He regards transplanting as impractical for extensive agriculture, and states that it brings lower yields than the ordinary drill seeding method.

Compilation of the results of tests of the Demtschinsky, Zehetmayr, and other cultural methods and their variations, A. EINECKE (*Landw. Jahrb.*, 41 (1911), No. 2, pp. 281-335, fig. 1; *abs. in Jour. Bd. Agr. [London]*, 18 (1912), No. 10, pp. 857-859).—This article is compiled from reports transmitted by the minister of agriculture of the Prussian Agricultural Chambers to the experimental and bacteriological institute of the Royal Agricultural High School. Much of the data presented has already been published, and has been noted from other sources.

The results obtained in these experiments, which were carried out in Germany, agreed fairly well, indicating that transplanting and deep setting of cereals is unprofitable. Although Demtschinsky estimates that from 16 to 20 days' labor per acre is sufficient in the use of this method, the extra labor required in these experiments varied from 53 days per acre in Pomerania to 120 days in Wiesbaden.

The results favored hilling up the plants in rows and indicated that this method prevented lodging without involving much extra labor. A special machine was used in planting. The effect of these treatments varied somewhat with the different cereals. Both earthing up and transplanting were favorable in case of winter rye on sandy and clay soils, but winter wheat was less favorably affected and the tests on spring rye were unsuccessful. Both these methods gave good results in 2 experiments on spring barley, but the results with oats were too variable to justify definite conclusions.

In general the Demtschinsky method resulted in longer heads and a greater production of grain per plant than the ordinary methods, and although unsuccessful financially, it drew the attention of German agriculturists to the possibilities of deep plowing and earlier, thinner seeding.

Tests of new grain culture methods, R. FRUWIRTH (*Wiener Landw. Ztg.*, 61 (1911), No. 33, pp. 385-387).—This is a report of experiments conducted to determine the merits of hilling up wheat, rye, and barley, and of covering the small plats with soil, as compared with the ordinary cultural methods. Tables state the weight of grain per 100 heads, the 1,000-kernel weight, the proportions of the kernels which passed through sieve meshes of various sizes, and the depth of drilling and covering.

In view of these and other tests the author does not feel that the recent severe criticism of these methods is any more justified than the earlier enthusiasm. He does not recommend any diminution in rate of seeding when they are used.

[Experiments with field crops], G. AUCHINLECK (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. [etc.] Grenada, 1910-11*, pp. 4-6).—In experimental sowings of *Crotalaria retusa*, indigo, Bambarra ground nuts (*Voandzeia subterranea*), *Tephrosia candida*, and the sword bean (*Canavalia gladiata*), only the last named germinated well under a cacao shade. Variety tests of sweet potatoes, yams, and tannias are reported. The quantity of seed set on both limed and unlimed rows of alfalfa was negligible and no apparent increase resulted from the tripping of alternate rows.

[Field crop tests in the Fiji Islands], C. H. KNOWLES (*Rpt. Agr. Fiji, 1910*, pp. 8-11).—Brief reports are given on work at the Lautoka Station with cotton planted continuously, and cotton planted after corn, rice, and green manure crops. The cost of lint per pound ranged from 8s. 9d. to 13s. 8d. Other work reported included a fertilizer test with cotton, a date of cutting test with sisal hemp, a variety test of corn, and a test of a rice huller and polisher. The cost per bushel of growing corn of the 4 varieties tested ranged from 1s. 2d. to 2s. 2d.

[Variety and other tests], J. W. HADFIELD (*Agr. Gaz. N. S. Wales, 23 (1912)*, No. 2, pp. 115-121, figs. 5).—Tests of varieties of wheat, oats, and mixed sowings of barley with rape and vetch are reported. Barley and rape proved the most effective winter mixture.

[Tests of new grasses], J. DUNCAN (*Jour. New Zeal. Dept. Agr., 4 (1912)*, No. 2, pp. 111, 112).—*Festuca dumetorum* is noted as giving special promise of proving a valuable grass at Kaitala and Okerama in the Whangarei district. Other grasses tested were *F. arenari*, *Agropyrum smithii*, *A. repens*, *Phalaris commutata*, *P. caroliniana*, *Paspalum dilatatum*, *P. virgatum*, and *Chloris gayana*.

The influence of time of cutting upon the yield and composition of hay, C. CROWTHER and A. G. RUSTON (*Jour. Agr. Sci., 4 (1912)*, No. 3, pp. 305-317).—The author presents mechanical and chemical analyses of the soil of the Yorkshire farm on which the hay used in these experiments was grown in 1909-10. The hay was a mixture of rye grass and rib grass with various clovers.

In 1909 the first cutting was made June 10 when the rye grass was in full flower and later cuttings on June 28, July 15, and August 3. Analyses of the hay indicate that the proportion of crude fiber increased steadily throughout the entire period, that the proportion of amids fell gradually up to the third cutting after which the reduction was very pronounced, and that a fall in proportion of true protein during the moist latter half of June was followed by a steady rise up to the time of the fourth cutting. The proportion of carbohydrates gradually fell after the second cutting, but the proportion of pentosans was relatively high throughout the period. The ash increased in richness in silica, but the proportion of potash and phosphoric acid tended to fall. Tables state in detail the numerical data obtained in the tests, and the author concludes from the 2 years' work that the nature of the changes depends upon the character of the season.

In 1909, when the season favored steady growth, the production of protein and fiber was steady and the assimilation of each of the ingredients, particularly silica, was considerable. In 1910, a severe climatic setback in the latter part of June was followed by an almost complete suspension of growth and notably of protein production. During both seasons there was a steady fall in the digestibility of hay, which in the end more than counterbalanced the increase in yield.

The best results followed cutting about July 1, but a latitude of a week or 10 days "may be allowed, however, without very seriously impairing the nutritive value of the crop." After July 15, however, appreciable deterioration occurred.

Tests on natural pastures, C. DUSSERRE (*Ann. Agr. Suisse, 12 (1911)*, No. 2, pp. 155-162).—These pages report the results of fertilizer tests on natural pastures conducted for a number of years at each of several points in the cantons of Neuchâtel and Valais, Switzerland.

Applications of (1) 576 kg. per hectare (512.64 lbs. per acre) of 14 per cent Thomas slag, (2) 240 kg. per hectare of 60 per cent chlorid of potash, and (3) the 2 applications together ranked in the order named in one locality as to net profits. In another locality applications of (1) 400 kg. of a 30 per cent potash salt, (2) 480 kg. of 17 per cent superphosphate, and (3) the 2 applications to-

gether gave crops containing 11.3, 10.7, and 12 per cent of protein, respectively, as compared with 10.5 per cent for the crop grown on the check plot. The net profits in this locality were lowest in case of the application of potash alone and highest in case of the mixture.

**Nitrogen fertilization of legumes,** G. RITTER (*Centbl. Bakt. [etc.]*, 2 *Abl.*, 29 (1911), No. 23-25, pp. 650-668, pls. 2).—The author briefly reviews earlier experiments on the subject and states at length the plan and results of his own tests with lupines.

He concludes that uninoculated virgin soil should be fertilized with nitrates or ammonium salts. A small amount of some nitrogen-supplying fertilizer should be added even when inoculation with pure cultures is practiced, but the best results are obtained by inoculation with soil from fields in which lupines have grown.

**The soy bean and cowpea,** C. G. WILLIAMS and F. A. WELTON (*Ohio Sta. Bul.* 237, pp. 241-261, figs. 2).—Discussions of the uses of soy beans and cowpeas accompany directions for growing and harvesting the crops in Ohio.

Seeding soy beans at the station at the rate of 3 pk. per acre produced higher total and higher grain yields than seeding at the rate of 1, 2, or 4 pk. per acre in rows 28 in. apart. Seeding at the rate of 8 pk. per acre in rows 8 in. apart produced a still higher forage yield but the difference was insufficient to pay for the extra seed used. The forage was more satisfactory because of fineness of stems. Sowing at the rate of 3 pk. per acre also gave the highest grain yield in a farmer's cooperative test.

Tables present descriptions of 32 varieties of soy beans tested and the yields secured during the period 1908-1911. Other tables group these varieties according to the length of the period required to ripen them, and report analyses as to protein and fat of 23 varieties of soy beans and 2 varieties of cowpeas in comparison with other feeds.

During the 3-year period 1909-1911, 10 varieties of soy beans produced average total yields of 3,528 lbs., and grain yields of 23.62 bu. of grain per acre. During the same period 3 cowpea varieties produced total yields ranging from 2,380 lbs. to 3,080 lbs. and grain yields ranging from 4.44 to 7.94 bu. per acre.

**Alfalfa as a field crop in South Dakota,** A. N. HUME and S. GARVER (*South Dakota Sta. Bul.* 133, pp. 259-281, figs. 6).—Tables state the results obtained in numerous variety tests at Brookings, Highmore, and other points in co-operation with the Bureau of Plant Industry of this Department.

From the data presented, the authors conclude that there is nothing to indicate that the source of the seed used at Brookings had any considerable influence on the hay yield, with the possible exception of the French seed. At Highmore, however, 6 years' average yields indicate that a choice of the proper strain may determine success or failure. Of the 4 strains that appeared sufficiently hardy for use at this point, "Turkestan proved most able to withstand conditions." It gave an average yield of 1.4 tons per acre during the 6 years.

In a test of strains of *Medicago sativa*, *M. falcata*, *M. media*, *M. ruthenica*, and *M. platycarpa* at Brookings, Highmore, and Cottonwood, plants which had been reset were compared. Almost all the strains tested at Brookings proved sufficiently hardy, but at Highmore a far greater percentage of the reset plants of *M. falcata* survived than of *M. sativa* or even *M. media*. At Cottonwood the surviving plants were practically all either *M. falcata* or *M. ruthenica*.

Hard seed was treated by a machine devised by Nilsson of Svalöf, Sweden. This is called the "Preparator," and consists essentially of a hopper so arranged as to drop the seed upon a revolving disk from which it is thrown by centrifugal force against the concave surface of a circular rough stone within which the disk revolves. On striking the rough surface, the seed coats are in-

dented or scratched and so weakened that water is more readily absorbed and the seed coat more easily broken by the swelling germ. Treated and untreated seed of *M. sativa* showed germination tests of  $99\frac{1}{2}$  and  $91\frac{1}{2}$  per cent, respectively, as compared with 94 and  $86\frac{1}{2}$  for *M. media*, and  $81\frac{1}{4}$  and  $62\frac{3}{4}$  for *M. falcata*.

**Right- and left-handedness in barley,** R. H. COMPTON (*Proc. Cambridge Phil. Soc.*, 15 (1910), No. 6, pp. 495-506, figs. 2).—The author's conception of right- and left-handedness in barley is illustrated in the accompanying figure (see fig. 1).

Observations of 8 varieties of two-rowed barley made to determine the ratio of lefts to rights in the first leaves of seed of different varieties, and of the various kernels from the same individual spikes, indicated that among 12,401 seedlings 7,237, or 58.36 per cent, "had the first leaf twisted in the left-handed fashion." The ratios obtained from the different varieties differed slightly, and "it appears probable that the difference between Plumage corn, and Guinness Goldthorpe, for example, is significant." Right- and left-handedness appeared not to be hereditary.

The same ratio was maintained whether the seed was taken from the odd or even rows of seed on the parent ear. The twist of the last leaf below a spike had no apparent influence on the ratio of right- to left-handed seedlings produced from the spike.

A further contribution to the study of right- and left-handedness, R. H. COMPTON (*Jour. Genetics*, 2 (1912), No. 1, pp. 53-70, figs. 4).—The work reported in this paper confirms the conclusions noted above in the case of two-rowed barley, indicating that "although the ratio of lefts to rights is maintained through 3 successive generations, the kind of asymmetry itself is not inherited." An excess of left-handed seedlings also appeared in six-rowed barley and no conspicuous variation of the ratio of lefts to rights among the

different rows of grain appeared. The numbers examined, however, were too small to be decisive.

A variety of millet (*Setaria italica*) also showed an excess of left-handed seedlings, 54.1 per cent being left-handed. Both stereo-isomeric forms were present in rye. In case of corn the ratio was almost unity (1.010), and there was apparently "no inheritance of right- and left-handedness as such." In case of oats 44.88 per cent of the seedlings were right-handed. The ratios obtained in case of corn kernels varied according to the position of the kernel on the cob, "the seeds on the odd orthostichies giving an excess of right-handed, those on even rows an excess of left-handed offspring" with some exceptions.

The author suggests that the difference in ratios results from a difference in shape of the material enclosing the developing embryo, and rejects as improbable an alternative hypothesis involving somatic segregation of symmetry characters in the gametes.

**Chou moellier at Moumahaki** (*Jour. New Zeal. Dept. Agr.*, 4 (1912), No. 2, pp. 117, 118, fig. 1).—Although this is the first test of chou moellier for this purpose at this locality, the author regards it as a decided success as a dry weather forage for milking stock.

FIG. 1.—Right- (R. H.) and left-handed (L. H.) stereo-isomeric seedlings.

[**Root cotton**], S. KUSANO (*Jour. Col. Agr. Imp. Univ. Tokyo*, 4 (1911), No. 1, pp. 67-82, pls. 2, fig. 1).—This so-called cotton is a fibrous cork tissue derived from the root of the tropical plant *Fagara integrifoliola*. It is at present used in caulking the seams of small boats. It is spoken of as unwettable, but takes up 16.2 per cent of its own weight in water when kept in a moist chamber for a week (maximum temperature 22° C.) or 26.1 per cent when kept in a steam sterilizer for 3 hours and left until the next day, as compared with 15.2 and 20.2 per cent respectively in case of ordinary commercial cotton. Its specific gravity is only about half that of ordinary cotton.

The bast fibers of *Gomphocarpus fruticosus*, A. IERZOG (*Tropenpflanzer*, 16 (1912), No. 3, pp. 113-125, figs. 8).—A brief review of the literature of the subject is followed by a statement of the results of observations of the water content and of the microscopic and other characters of the fibers. Tables state the results of measurements of the cells and micro-photographs show the structure of the fibers.

The origin of cultivated oats, TRABUT (*Bul. Soc. Hist. Nat. Afrique Nord*, 1910, No. 9, pp. 150-161, figs. 5).—This contribution to the study of the origin of cultivated oats deals with *Avena sterilis*, *A. fatua*, and *A. barbata*.

A comparative test of lime-sulphur, lead benzoate, and Bordeaux mixture for spraying potatoes, F. C. STEWART and G. T. FRENCH (*New York State Sta. Bul.* 347, pp. 77-84, pls. 4).—The experiments described were conducted for the purpose of determining the relative merits of lime-sulphur 1:40, lead benzoate (1 lb. to 50 gal.), and Bordeaux mixture (6:6:50) for spraying potatoes.

The authors conclude that "the results indicate plainly that neither lead benzoate nor lime-sulphur can be profitably substituted for Bordeaux mixture in spraying potatoes. Both lack the stimulative influence possessed by Bordeaux while lime-sulphur also dwarfs the plants and lowers the yield."

The Bordeaux rows yielded 100.3 bu. per acre more than the checks, while the benzoate and lime-sulphur rows yielded respectively 6 and 39.5 bu. less than the checks. None of the mixtures burned the foliage, but the lime-sulphur rows were as badly affected with tip burn as were the check rows.

Lime-sulphur dwarfs potato plants, F. H. HALL (*New York State Sta. Bul.* 347, popular ed., pp. 2, fig. 1).—This is a popular edition of the above.

Soy beans, G. ROBERTS and E. J. KINNEY (*Kentucky Sta. Bul.* 161, pp. 107-131, figs. 2).—This is a brief manual of information for the soy bean grower in Kentucky. Notes on a number of varieties tested are given.

Three-year average yields after planting in rows 28 in. apart were not enough higher than those secured from rows 35 in. apart to pay for the extra trouble of cultivation. Sowings of 55 lbs. per acre generally excelled in seed yield those of 30 lbs. per acre.

The soy bean and its uses, A. C. TONNELIER (*La Soja Hispida y sus Aplicaciones*. Buenos Aires, 1912, pp. 16, figs. 4).—This brief manual of information on the soy bean quotes many authorities, and reports an analysis of the "green forage" of the plant and the yield secured in a test which the author regards as favorable to the growth of the plant in his locality.

Tobacco culture in Ohio, A. D. SELBY and T. HOUSER (*Ohio Sta. Bul.* 238, pp. 263-359, figs. 23).—Earlier tobacco work at the Ohio Station has already been noted (E. S. R., 16, pp. 870, 886; 17, p. 245; 18, p. 696). This bulletin discusses the early history of tobacco culture in Ohio, and gives statistical and other studies on its present status and directions for tobacco growing, harvesting, curing, and marketing in that State.

In a rate of planting test the plants were spaced 16, 20, 24 in. etc. up to 40 in. apart in rows 34 in. apart. Those planted 16 in. apart gave the highest yields

per acre of filler, wrapper, and trash. The decrease in yield and in total value per acre resulting from wider plantings was continuous. The most closely planted tobacco was rather flimsy, perhaps because of immaturity and delayed ripening, but the fact that the entire crop was harvested at the same time was probably unfair to the closer plantings as these were somewhat less mature.

During the years 1906 and 1907 the total average gain from suckering as compared with allowing the crop to go without attention until cutting time amounted to 340 lbs. per acre or \$36 per acre. In 1910 the gain amounted to 193 lbs. or \$20.07 for twice suckering, and 247 lbs. or \$24.53 in case of that suckered 3 times.

In tests of time of harvesting Zimmer Spanish tobacco in 1909, that which was allowed to stand 25 and 27 days after topping gave 18.81 per cent greater total weight than that which stood only 20 and 22 days. The gain in wrapper and filler was 13.28 and that in total value 14.23 per cent. In another test tobacco cut 23 and 27 days after topping gave 12.94 per cent greater total weight than that cut 2 days sooner, 9.21 per cent loss in wrapper and filler and 5.56 per cent loss in total value. In a third test a crop which stood 27 days showed 6.61 per cent greater total weight than that which stood only 22 days, 4.44 per cent gain in wrapper and filler and 4.92 per cent gain in total value, while that which stood 32 days showed gains of 10.62, 10, and 10.11 per cent, respectively.

In 1910 cuttings were made 2, 3, 4, 5, and 6 weeks after topping. The increase in yield of wrapper and filler and in total value was continuous up to the last cutting. In case of 3 hybrids cut in part 4 weeks after topping and in part 4 days later distinct gains in yield and value were observed. These hybrids were top suckered just before the first cutting.

Among 34 varieties and hybrids Pennsylvania Broadleaf and Black Seedleaf produced the highest average yields during 1908-1910. Tables indicate also the yields secured in 1910 and the relative merits of hybrids and varieties based upon the yields of their best selections in 1910.

A table presents an itemized statement of the cost of each of 13 operations in connection with growing and marketing tobacco as carried on by 7 Zimmer Spanish growers. The author calls attention to the fact that many factors in cost of production remain constant or nearly so and that the important point is not the cost of production per acre but the production cost per unit of product. He estimates that while the 7 farmers quoted spent \$44.94 on the operations specified and secured average profits of \$47.92, an expenditure of \$60 per acre might bring a profit of \$65 per acre. A table indicates the recommended distribution of the expenditure among the various operations.

Historical and cultural notes on Zimmer Spanish tobacco are followed by briefer notes on a number of other varieties.

[Tobacco varieties and tests in Imosk and Sinj], K. PREISSECKER (*Fachl. Mitt. Österr. Tabakregie*, 11 (1911), No. 2, pp. 63-86, pls. 5, figs. 3; *abs. in Bol. Tec. Colliv. Tabacchi [Scafati]*, 10 (1911), No. 5, pp. 283-294).—A statement of the principal tobacco varieties grown in Dalmatia and of data obtained in tests of a number of hybrids accompanies discussions of the commercial status of tobacco in Bosnia, Herzegovina, and Japan.

The use of artificial heat in curing cigar-leaf tobacco, W. W. GARNER (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 241, pp. 25, figs. 4).—This bulletin presents in popular form some results of several years' experiments in the Connecticut valley.

These tests have proved "that by the use of artificial heat the curing can be successfully accomplished during the most unfavorable weather conditions, and methods for accomplishing this end are outlined." Heretofore the application of artificial heat in curing cigar tobaccos has been restricted almost en-

firely to the use of open charcoal or wood fires in curing shade-grown wrapper leaf. Experiments on a commercial scale in cooperation with growers have demonstrated the value of artificial heat in general for curing cigar types. A method of applying heat by the use of a furnace and flues, which has given very satisfactory results, has been worked out in detail.

The topics discussed include the conditions essential to the changes in properties and composition during the process, the prevention of pole-sweat, or pole-burn, the effect of the use of artificial heat on quality, the use of charcoal and flues in curing, and the construction of barns adapted to the use of heat.

[**Tobacco hybrid and Mendelian inheritance**], V. PAOLINI (*Bol. Tec. Coltiv. Tabacchi [Scafati]*, 10 (1911), No. 5, pp. 268-272).—The author discusses a local tobacco hybrid with special reference to Mendelian inheritance. This "Salento" hybrid was produced by crossing 2 varieties designated as Kentucky and Cattaro.

[**Seed analyses and plant breeding at Zurich**], F. G. STEBLER (*Landw. Jahrb. Schweiz*, 26 (1912), No. 1, pp. 16).—This report presents data for 1910 similar to the report already noted (E. S. R., 23, p. 239).

**Agricultural observations in North America, with special reference to plant breeding**, K. VON RÜMKER and E. VON TSCHERMAK (*Landw. Jahrb.*, 39 (1910), *Ergänzungs*b. 6, pp. XVI+151, pls. 22).—This is a review of the various lines of research in plant and animal breeding in North America, especially in plant breeding, together with a brief account of the agricultural institutions of the United States and descriptions of typical agencies.

**Organization for plant breeding**, K. VON RÜMKER (*Ueber Organisation der Pflanzenzüchtung*, Berlin, 1909, pp. 56).—The author discusses the organization of the plant-breeding work conducted in Vienna, Loosdorf, Weihenstephan, Munich, Hohenheim, and Svalöf. References are given to other publications which deal with the work at some of these points.

## HORTICULTURE.

**Influence of crossing in increasing the yield of the tomato**, R. WELLINGTON (*New York State Sta. Bul.* 346, pp. 57-76).—This comprises a study of the effect of cross-fertilizing related tomato varieties on the yield of the hybrid plants. Some of the more important experiments in plant hybridization are reviewed and a bibliography is appended. Suggestions are given for growing hybrid seed.

The experiments were conducted in the summers of 1908-1910 and also in the winter of 1908-9. The first experiment was started with seed from self-fertilized plants of the Livingston Stone and Dwarf Aristocrat and from Dwarf Aristocrat  $\times$  Livingston Stone, and Dwarf Aristocrat  $\times$  Hedrick. The yield from the first generation ( $F_1$ ) seedlings resulted in a marked increase over the yield of the parent forms. Similar results were secured with  $F_1$  seedlings in the summers of 1909 and 1910. The 1908-9 winter experiment comprised a test of  $F_2$  seedlings, all of the dwarf plants that appeared in this second generation being discarded. The results were similar to those secured in  $F_1$  summer tests although the differences in favor of the crosses were much less marked.

The summer experiment in 1909 was conducted with  $F_1$ ,  $F_2$ , and  $F_3$  seedlings. The  $F_1$  and  $F_2$  seedlings showed practically the same increase in yield over the parent forms, whereas the yield of  $F_3$  seedlings was nearly identical with the Livingston Stone parent. The experiment in 1910 was continued to the fourth generation of seedlings. The  $F_1$  seedlings gave the highest yield, the  $F_2$  seedlings the next highest, whereas the  $F_3$  and  $F_4$  seedlings both gave yields considerably

lower than the Livingston Stone parent. In all cases the yield of the standard parent was much greater than that of the dwarf parent.

In the light of this and similar investigations here reviewed, the author concludes that the increase in vigor and size produced by crossing is undoubtedly due either to the heterozygous condition, which stimulates the growth of either the size or the number of cells, or to a combination of two or more size-increasing characters, such as thick internodes and long internodes, which dominate over characters of decreasing dimensions. All of the crosses gave consistent gains in favor of the yield of  $F_1$  seedlings. The yields from the  $F_2$  and  $F_3$  seedlings appear to have fallen off in direct ratio to the decrease in the number of heterozygous plants. When, however, a homozygous condition for all the plants in a strain has been obtained, the average yield of the plant should remain constant from year to year, varying only with the external factors. The author further concludes that the results as a whole warrant the production of  $F_1$  generation tomato seed, not only by the growers but by all seedsmen who wish to furnish the best grade of seed to the buyers.

Crossing tomatoes to increase the yield, F. H. HALL (*New York State Sta. Bul.* 346, popular ed., pp. 8).—A popular edition of the above.

Preliminary report on tomato culture, L. L. CORBETT (*Virginia Truck Sta. Bul.* 8, pp. 157-171, figs. 5).—This comprises popular directions for growing tomatoes in eastern Virginia. Consideration is given to propagation, including the use of the hotbed and cold frame; hardening; soil and preparation; planting; spraying; diseases and insects; types of fruit; harvesting and packing; marketing; and canning. Results are also given of varieties tested at the station showing the character of growth, form and color of fruit, date of first ripening, duration of picking period, and number and weight of fruit.

[Phenological notes: **Blooming dates for Iowa plants, 1911**], CHARLOTTE M. KING ET AL. (*Trans. Iowa Hort. Soc.*, 46 (1911), pp. 200-211).—A continuation of previous reports (*E. S. R.*, 26, p. 237). The records for 1911 are given by a number of observers from different parts of the State showing the dates of first blooming of trees, shrubs, and flowering plants.

The avoidance and prevention of frost in the fruit belts of Nevada, J. E. CHURCH and S. P. FERGUSSON (*Nevada Sta. Bul.* 79, pp. 58, pls. 16).—Part 1 of this bulletin, which deals with the prevention of frost, describes in detail heating experiments conducted by the station in 3 orchards during the spring season of 1911, and discusses methods of preventing frost by the use of wind-breaks and orchard heaters. A brief account is given of frost phenomena and general weather changes, together with a discussion of the methods of forecasting frost, including descriptions with illustrations of the necessary apparatus. Estimates are also given on the cost of orchard heating.

The second part of the bulletin deals with the avoidance of frost. A series of temperature measurements taken in 1910 are given to show the value of higher ground as a natural site for orchards. A temperature survey of the agricultural land of the State has been inaugurated with the view of determining large areas suitable for fruit raising under all forms of economic frost prevention and also to delimit thermal belts in these areas into (1) belts where frost does no material damage to fruit crops; (2) belts where frost can be successfully combated at reasonable expense; and (3) belts where frost is so severe as to make fruit raising unprofitable. A progress report is given of this work, which during the past season included the establishment of 5 different stations in the Truckee Meadows and located at different altitudes. The temperature records secured at these stations are given and discussed. They indicate a preponderance of low temperatures at the lower stations.

A preliminary temperature survey of the State covering the years 1901-1911 and based upon the climatological records of the U. S. Weather Bureau was also made. Descriptions are given of the thermal stations in Nevada with mean temperature observations during the above period, together with similar data for Utah and Colorado. A bibliography on orchard heating, together with suggestions on tree planting by A. A. Heller, is appended.

The authors conclude that orchards in Nevada can be protected, even during a season when the temperature falls as low as 22° F. and frosts occur persistently, at an expense varying from 73 to 95 cts. per tree. Windbreaks consisting of the Russian oleaster, lopped poplars or willows, and Lombardy poplars are recommended as a material aid in economic and effective orchard heating. The windbreaks are essential to success wherever the wind is strong. From the temperature data already secured it is concluded that many sections in Nevada contain areas that can be adapted by orchard heating to the raising of fruit. The Moapa Valley is practically frostless.

Varieties of fruits raised in Oklahoma. N. O. BOOTH and D. C. MOORING (*Oklahoma Sta. Bul. 95, pp. 3-48*).—A descriptive list is given of the varieties of apples, crabapples, pears, quinces, peaches, plums, cherries, grapes, blackberries, dewberries, loganberry, raspberries, strawberries, and gooseberries, which have been tested by growers in Oklahoma. The number of growers who have been successful and those who have been unsuccessful with each variety are indicated.

How to make old orchards profitable. F. A. BATES (*Boston, 1912, pp. 123, figs. 13*).—A popular treatise on orchard renovation.

The apple orchard from planting to bearing age. A. L. DACY (*West Virginia Sta. Bul. 136, pp. 161-206, figs. 23*).—A popular bulletin discussing the various operations involved in planting an apple orchard and in its subsequent care up to the bearing age.

The profitable management of the small apple orchard on the general farm, M. C. BURRITT (*U. S. Dept. Agr., Farmers' Bul. 491, pp. 22, figs. 8*).—This bulletin deals specifically with the renovation of old apple orchards. After classifying the orchards it will not pay to renovate, the details are given for pruning, fertilizing, cultivating, and spraying neglected orchards, including a discussion of the cost and profits from renovated orchards. Important references to the subject of orchard renovation are noted.

The more important insect and fungus enemies of the fruit and foliage of the apple, A. L. QUAINANCE and W. M. SCOTT (*U. S. Dept. Agr., Farmers' Bul. 492, pp. 48, figs. 21*).—This publication, which is based upon the results of the Department's investigations during the past several years, describes the more important insect and fungus enemies of the fruit and foliage of the apple, together with the most economical methods of combating them.

The cherry orchard as a commercial venture, G. B. HEALY (*Trans. Iowa Hort. Soc., 46 (1911), pp. 256-259*).—Some data are given on the cost of growing cherries on a commercial scale.

A supposed case of parthenogenesis among olives, G. CAMPBELL (*Nuovo Gior. Bot. Ital., n. ser., 19 (1912), No. 1, pp. 86-89, pls. 2*).—The author reports a case of supposed parthenogenesis observed in an olive grove where abortion of the female flowers occurred quite frequently.

Strawberry notes for 1910, 1911, W. J. GREEN, J. H. GOURLEY, and P. THAYER (*Ohio Sta. Bul. 236, pp. 211-239, figs. 56*).—This bulletin contains notes on the condition and character of strawberry varieties tested at the Ohio Station during the seasons 1910 and 1911. Many of the varieties are illustrated. Lists are given of promising varieties for market, dessert, and canning, and for high yield and long-season fruiting.

A test of a number of autumn fruiting varieties indicates that the smallness of the fruit renders these varieties of little commercial importance, although they are worthy of consideration in the home garden.

In a test of hill culture versus the matted row system, the hill grown berries averaged  $1\frac{1}{2}$  days earlier for the first picking and 7 days earlier for the last picking. The quality was unaffected by the method of culture.

**Strawberry culture**, G. MARTELLI (*La Coltivazione delle Fragole. Catania, 1912, pp. 51, figs. 11*).—A popular treatise on the history, botany, culture, and uses of the strawberry.

**The cherimoya in California, with notes on some other anonaceous fruits**, F. W. POPENOE (*Pomona Col. Jour. Econ. Bot., 2 (1912), No. 2, pp. 277-300, figs. 16*).—The cherimoya (*Annona cherimolia*) is here described with reference to its botany, origin, common names, climatic requirements, propagation, culture, diseases, insect pests, season, shipping qualities, nature and extent of seedling variation, and varieties, together with information relative to the present status of its culture in California. Other species of *Annona* fruited in California, as well as all of the anonaceous fruits introduced there, are also described.

**Feijoa sellowiana, its history, culture, and varieties**, F. W. POPENOE (*Pomona Col. Jour. Econ. Bot., 2 (1912), No. 1, pp. 217-242, figs. 13*).—The Feijoa, a comparatively new fruiting shrub from South America which gives promise of thriving throughout the warm sections of the United States, is here discussed relative to its history, botany, introduction and trial in various parts of Europe and North America, methods of propagation, climatic requirements, culture, season, the fruit and its uses, keeping and shipping qualities, diseases and insect pests, and variation and varieties.

**Wild fruits which ought to be cultivated**, C. E. BESSEY (*Nebr. Hort., 2 (1912), No. 4, pp. 1, 5-8*).—The author discusses somewhat in detail a number of wild fruits of Nebraska which are considered worthy of cultivation.

**The palms indigenous to Cuba**, I. O. BECCARI (*Pomona Col. Jour. Econ. Bot., 2 (1912), No. 2, pp. 253-276, figs. 10*).—This is a contribution to the knowledge of the palm flora of Cuba. The present part contains a conspectus of the genera and conspectuses of the *Oreodoxa*, *Pseudophoenix*, and *Gaussia*.

**[Cacao manurial plats in Dominica]**, H. A. TEMPANY (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. Dominica, 1910-11, pp. 22-32*).—This is a progress report on the fertilizer and mulching experiments being conducted with cacao at the Dominica Botanic Station, including the results of fertilizer experiments conducted in several country districts. The results as a whole confirm those previously noted (E. S. R., 24, p. 545).

**Spices**, H. N. RIDLEY (*London, 1912, pp. 1X+449, figs. 15*).—A handbook of information relative to the history, cultural requirements, exploitation, and uses of the following spices and condiments: Vanilla, nutmegs and mace, cloves, pimento or allspice, cinnamon, cassia bark, massoy bark, black peppers, long pepper, grains of paradise, cardamoms, capsicums or chilies, coriander, dill, cumin, ginger, turmeric, zedoary, galangal, and calamus root.

**Everblooming roses**, GEORGIA T. DRENNAN (*New York, 1912, pp. XII+250, pls. 16*).—A popular work treating of the culture, habits, characteristics, care, nativity, and parentage of roses, with authentic guides to the selection of everblooming varieties.

**Preparation and use of the concentrated lime-sulphur spray**, J. P. STEWART (*Pennsylvania Sta. Bul. 115, pp. 3-23, figs. 3*).—This bulletin, which replaces Bulletin 99 (E. S. R., 23, p. 266) of the same series, brings the results and recommendations relative to the preparation and use of concentrated lime-sulphur spray up to date.

On the occurrence of arsenate of lead in the wine, lees, and seeds obtained in vineyards treated with arsenate of lead, P. CARLES and L. BARTHE (*Bul. Soc. Chim. France*, 4. ser., 11 (1912), No. 8, pp. 413-417).—Analyses of wines taken from vines sprayed with an excess of arsenate of lead showed only slight traces of arsenic and of lead. No arsenic or lead were found in wines obtained from vines normally treated. Larger amounts of arsenic and of lead were found in the lees of grapes receiving arsenical sprays, however, and the authors conclude that where the wines contain an undue proportion of lees a certain amount of the arsenic and the lead will occur in the wine. The danger of poisoning from this cause, however, is not considered serious.

## FORESTRY.

Second-growth hardwoods in Connecticut, F. H. FROTHINGHAM (*U. S. Dept. Agr., Forest Serv. Bul.*, 96, pp. 76, pls. 6, figs. 3).—This comprises the results of a study conducted cooperatively by the Forest Service and the Connecticut State Station to determine the rate of growth of second-growth hardwoods in Connecticut, the value of the standing timber for different uses, and the method of management to secure the maximum yield of most valuable material in the shortest time.

Part 1 deals with the present forest conditions in Connecticut, including a description of the second-growth types. Part 2 discusses methods of selling timber, market values and uses of native forest products, logging costs, and value of standing timber for different uses. In part 3 the factors which influence the yield of even-aged hardwood stands are discussed. General yield tables, together with yield tables for cordwood, lumber, ties, and poles are given with directions for their use. Growth tables for average even-aged hardwood stands are also included. In part 4 the management of hardwood stands is discussed under the general headings of choice of species, factors influencing rotation, thinnings, final cutting and reproduction, protection, and financial returns. A number of volume tables, together with tables showing the yield of individual oak and oak-chestnut stands are appended.

The testing of pine seeds, HAAK (*Ztschr. Forst u. Jagdw.*, 44 (1912), Nos. 4, pp. 193-222, figs. 7; 5, pp. 273-307, pl. 1).—In continuation of previous investigations (E. S. R., 21, p. 441), extensive experiments were conducted in 1910 and 1911 to study the influence of individual germination factors, such as the time of the year when tests are made, moisture, heat, light, and chemical treatment of seed, as well as to determine the practical application of the ratio between the germinative energy of a seed sample and the number of seedlings produced therefrom in determining the market value of the sample. The experiments are described in detail, together with a discussion of their application and value as compared with methods generally used in testing pine seeds.

The author found that tests of pine, and spruce seeds as well, may be conducted at any time of the year, providing conditions favorable to germination, such as moisture, heat, and light can be provided for.

Although germination at low temperatures was found to begin later and to spread out over a longer period than at high temperatures, the relation between germination temperature and the germination duration is such that the product of the time period and the number of seedlings is practically the same whether the tests are conducted at high or low temperatures. Varying high temperatures have a stimulating effect on the germination of pine seed but not on spruce seed. This effect is somewhat similar to the effect of light exposure but not so powerful as the latter effect. A constant temperature of 25° C. is recommended for seed testing stations.

All parts of a spectrum acted favorably on the germination of pine seed, the long undulating rays being most beneficial and the short blue rays less beneficial. Spruce seed was acted on favorably only by the red and yellow light and may be directly injured by the blue light.

In making seed tests it is sufficient to germinate the seed under light conditions for a period of from 8 to 10 hours daily. The best degree of light is one in which reading can be easily done. There was no important difference between the influence of daylight and of artificial light. Daylight tests should preferably be conducted in rooms facing the north, where they will not be exposed to the direct sunlight.

Other conditions being equal the germination process of different seed samples may be traced in a curve, the latter course of which can be readily traced by accurately recording the course of the curve during the first few days after germination. For practical purposes a 12-day observation of tests conducted at 25° is considered sufficient.

Experimental rubber cultivation, J. B. HARRISON (*Rpt. Dcpt. Sci. and Agr. Brit. Guiana, 1910-11, pp. 8-13*).—A progress report on cultural and tapping experiments with indigenous and imported varieties of rubber yielding plants during the year 1910-11 is presented.

The rubber industry, edited by J. TORREY and A. S. MANDERS (*London [1912], pp. 470, figs. 51*).—This is the official report of the proceedings of the International Rubber Congress, London, 1911.

In addition to the matters relating to the organization and the functions of the congress the following papers were presented: Rubber in Uganda, by R. Fyffe (pp. 45-58); The Production of Rubber in Madagascar, by the colonial government of Madagascar (pp. 59-68); Lecture on the West Indies, by F. A. Stockdale (pp. 69-72); The West African Varieties of Latex and Raw Rubber, by M. C. Hugot (pp. 73-80); Rubber Plantations in French Cochinchina, by A. Cremazy (pp. 81-86); Rubber Trees and Wild Rubber Reserves of the Amazon, by J. Huber (pp. 87-98); The Rubber Industry in Peru, by E. Castre (pp. 99-104); The Rubber Problem in French Western Africa, by A. Chevalier (pp. 105-119); Notes on the Planting and Production of Rubber in Ceylon, by K. Bamber (pp. 120-131); The Need of Organization in the Supply of Literature and Labor for Rubber and Other Planters, by H. H. Smith (pp. 135-141); Official Measures against Adulteration of Wild Rubber, by G. van den Kerkhove (pp. 142-148); The Maintenance of Health in Rubber Planting Districts, by W. C. Brown (pp. 149-159); The Para (Hevea) India Rubber Tree in the East, by H. A. Wickham (pp. 163-168); The Mannring of Rubber Trees, by E. Lierke (pp. 169-179); Some Diseases of *Hevea brasiliensis*, by J. Mitchell (pp. 180-189); Tapping Experiments on *H. brasiliensis*, by W. R. Tromp de Haas (pp. 190-196); African Rubber Vines: Their Cultivation and Working, by E. de Wildeman (pp. 197-209); Notes on the Cultivation of Para Rubber, by W. Fox (pp. 210-215); Some of the Constituents of *Parthenium argentatum* (Gray), The Shrub from which Comes the So-Called "Guayule Rubber," by P. Alexander (pp. 216-222); On the Physical Constitution of Caoutchouc-Bearing Latices and the Relation of the So-Called "Coagulation" thereto, by H. C. T. Gardner (pp. 225-230); The Centrifugalization of Rubber Latex, by H. S. Smith (pp. 231-233); The Discovery of the Para Reagent, by W. Pahl (pp. 234-242); Viscosity of Hevea Latex at Various Dilutions, by Miss A. T. Borrowman (pp. 243-247); Some Remarks on the Preservation of Rubber and on the Preparation of Plantation Rubber, by W. Esch (pp. 248-259); The Viscosity of Rubber and its Solutions, by P. Schidrowitz and A. H. Goldsbrough (pp. 260-264); Raw Rubber Testing, by C. Beadle and H. P. Stevens (pp. 265-284); India Rubber Research, by F. Frank (pp. 301-305); Theory of Vulcanization, by W. Hinrichsen (pp.

306-310); The Adaptation of Different Raw Rubbers for Manufacturing Purposes, by J. Jaques (pp. 311-317); The Technical Use of Plantation Rubber and the Conditions which, in the Production of Raw Rubber, are of Importance for its Technical Application, with Special Reference to *Kickxia* (*Funtumia*) and *Manihot* Rubber, by F. Frank (pp. 317-326); The Extensibility of Vulcanized Rubber, by C. Chéneveau and F. Heim (pp. 327-335); The Oxidation of Sulphur by Nitric Acid, by H. E. Potts (pp. 336-343); Impact-Tensile Tests on Rubber and a Comparison with Tensile and Hysteresis Tests, by C. Beadle and H. P. Stevens (pp. 344-350); Mechanical Tests for Rubber, by K. Memmler (pp. 351-373); The World's Trade in Raw Rubber, by E. Hecht (pp. 377-380); and Factors Affecting the Valuation of Rubber Shares, by W. Tinnoek (pp. 381-389).

Method and tables for the determination of the volume and value accretion in standing trees, E. ANDERSSON (*Skogsvårdsför. Tidskr., 1912, Fackafd., No. 1, pp. 29-32, figs. 3*).—The derivation and use of tables for the determination of volume and value accretion are here described.

State afforestation in New Zealand, W. C. KENSINGTON (*New Zeal. Off. Year-book, 1911, pp. 815-824*).—The author calls attention to the need of afforestation in New Zealand and describes the work which the government has been doing along this line in recent years.

The Deliblat sand barrens in southern Hungary, E. VON ARJAY (*Österr. Vrtljschr. Forstw., n. ser., 30 (1912), No. 1, pp. 43-66*).—A historical and descriptive account of afforestation and sand dune reclamation in the above named region.

A review of the results of the Saxony state forest administration for the year 1910, VOGEL (*Tharand. Forstl. Jahrb., 63 (1912), No. 2, pp. 143-157*).—A statistical and financial statement of the work and results of the forest administration for 1910.

Annual report on the forest administration in Ajmer-Merwara for 1910-11, HUKAM CHAND (*Ann. Rpt. Forest Admin. Ajmer-Merwara, 1910-11, pp. 39*).—The annual report on the constitution and management of the state forests of Ajmer-Merwara, including a financial statement for the year. Important data relative to areas, miscellaneous forest operations, expenditures, revenues, etc., are appended in tabular form.

Progress report of forest administration in the Punjab for the year 1910-11, C. P. FISHER (*Rpt. Forest Admin. Punjab, 1910-11, pp. 3+20+LI*).—A report similar to the above relative to the administration of state forests in Punjab.

Annual report of the forest administration for the year 1910-11 (*Pflanzer, 8 (1912), Beiheft 1, pp. 42, pls. 6*).—This comprises the annual report on the constitution, management, and exploitation of the forests in the various districts of German East Africa. The important data are appended in tabular form.

## DISEASES OF PLANTS.

Notes on new or little-known plant diseases in North America for 1910, F. D. HEALD (*Phytopathology, 2 (1912), No. 1, pp. 5-22*).—A critical review is given of literature relating to various plant diseases reported in 1910.

Two dangerous imported plant diseases, P. SPAULDING and ETHEL C. FIELD (*U. S. Dept. Agr., Farmers' Bul. 489, pp. 29, figs. 3*).—Popular descriptions are given of the white pine blister rust due to *Peridermium strobi* and the potato black wart caused by *Chrysophlyctis endobiotica*. Both of these diseases have been introduced from Europe, the first in the importation of young pine seedlings and the second by the importation of potatoes. Thus far the potato dis-

case has been reported in North America only from Newfoundland. Attention is called to the desirability of a quarantine as a means for preventing the further introduction and establishment of these diseases.

A review of literature relating to diseases of sugar beets and potatoes, A. STIFT (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 17-19, pp. 447-496).—This is a critical review of some of the more important literature relating to the diseases of sugar beets and potatoes and their control.

The control of the loose smuts of barley and wheat, K. STÖRMER ET AL. (*Deut. Landw. Presse*, 38 (1911), Nos. 88, pp. 1005, 1006; 89, p. 1017).—A study has been made of different methods of seed treatment for the prevention of the loose smuts of barley and wheat, especial attention being given the modified hot-water method. The relation of temperature and duration of the preliminary soaking of the seed grain to the water content of the seed was investigated, and also the maximum, minimum, and optimum temperatures for the germination of the smut spores and the development of the mycelium.

It was found that the spores germinate at temperatures between 5 and 35° C. and that the mycelium begins to grow at temperatures just below 6° and growth ceases at 34°. The maximum water content of the grain, about 32 per cent, was attained in preliminary treatments of 12 hours' soaking at 6° or 4 hours at 30°. The relation of this temperature to water content is discussed at length.

As practical methods for seed treatment, based on the observations of the authors, they recommend (1) soaking barley for 12 hours at 35° and wheat at 40°, and (2) a preliminary soaking for 4 hours at from 25 to 35° for barley and wheat, after which the seed is dipped for 10 minutes in water heated to 50 to 52° for barley and 52 to 53° for wheat. In place of hot water, hot air for  $\frac{1}{2}$  hour may be substituted without drying the grain, 50 to 52° being maintained for barley and 52 to 53° for wheat. Where large amounts of seed are to be treated, forms of hot-air apparatus coupled with drying may be used, the temperature in the latter case falling to 40°.

Grain smuts and their control, O. BROZ (*Monatsh. Landw.*, 4 (1911), No. 10, pp. 289-293, figs. 4; 5 (1912), No. 1, pp. 17, 18).—After giving a brief discussion of the various grain smuts, the author recommends three methods of treatment for infected seeds as follows:

Copper sulphate solution of 0.5 per cent strength is used to steep the grain, vigorously stirring the mass meanwhile. In the same way formaldehyde may be used, being made up to 1 or 2 per cent strength by adding to 100 liters of water 250 or 500 gm. of the 40 per cent commercial solution (formalin). The Jensen hot water treatment is preferred to the hot air treatment, and is said to destroy the mycelium which is claimed to arise from spore infection of the seed during its development in the parent flower. In the application of this treatment the grain, enclosed in very loose sacks, is steeped in water at 20° C. for 12 hours, then each sack is agitated for 1 minute in a vat at 46° and lastly for 10 minutes in a vessel at 50° to 52° in case of wheat or at from 48° to 50° in case of barley (higher temperatures will affect germination), and at once cooled in cold water and thoroughly dried. It is recommended that the seed be planted soon after treatment.

The leaf spot of oats, B. TACKE (*Mitt. Deut. Landw. Gesell.*, 26 (1911), No. 3, pp. 26-28; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 31 (1911), No. 11-15, p. 321).—The author regards the so-called dry spot of oats, as well as somewhat similar troubles with other cultivated plants, as the result of nutritive disturbances due to overliming. The remedy indicated is the employment of fertilizers relatively low in lime.

Flower infection with cotton boll rots, C. W. EDGERTON (*Phytopathology*, 2 (1912), No. 1, pp. 23-27, pl. 1; *abs. in No. 2*, p. 98).—The studies of Barre

(E. S. R., 22, p. 648) relating to flower infection by the fungus causing cotton anthracnose led the author to investigate the subject at some length. He claims that infection of cotton bolls following flower inoculation can take place in either of two ways. The system may grow saprophytically upon the dead flower parts and finally grow through and into the boll, or it may cause the disease by growing down through the pistil into the boll. The anthracnose probably follows both methods, while the cotton bacterium (*Bacterium malvacearum*) infects the bolls through the first method.

The author carried on a large number of inoculations in which he injected organisms suspended in water into the flowers, and determined the infection. More than half of the diseased bolls were attacked at the tip, while the percentage of infection along the lines of dehiscence was small. When the bolls are small they are readily infected with anthracnose, though, so far as the observations of the author go, no one part of the boll is more susceptible than another. It is evident that the bolls may be infected through the flowers, but the author claims that this is not the usual method of infection.

*Sclerotinia panacis* n. sp. the cause of a root rot of ginseng, W. H. RANKIN (*Phytopathology*, 2 (1912), No. 1, pp. 28-31, pl. 1, fig. 1).—While investigating the diseases of ginseng in 1909, the author became interested in the disease commonly known as black rot (E. S. R., 22, p. 246). Subsequent investigations showed a rather widespread infection, and specimens were collected and kept in a culture chamber at ordinary room temperature, but no growth followed.

In 1910 a further study was made and the perfect stage of the fungus discovered. This differed from the species of *Sclerotinia* already described. Primary infection of the roots seemed to occur at no regular place, as they were found to start either at the crowns or in smaller roots.

Control measures have not been definitely determined, but the eradication of affected roots and soil sterilization with formaldehyde or steam are recommended.

A technical description of the fungus, *S. panacis* n. sp., is given.

Infection experiments with potato fungi, H. W. WOLLENWEBER and O. SCHLUMBERGER (*Mitt. K. Biol. Anst. Land u. Forstw.*, 1911, No. 11, pp. 15-17; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, p. 315).—The authors infected tubers with spores of *Verticillium alboatrum*, *Fusarium solani*, *F. cæruleum*, *F. orthoceras*, *F. subulatum*, and *F. discolor* by means of the Pravaz spray.

It was found that the spores of *F. cæruleum* and *F. solani* germinated in part and caused in isolated cases a slight rotting which did not extend to the whole tuber in any case. The other infections gave negative results. No decisive results were obtained by infection of stems and roots with the spores of the fungi named.

The natural distribution of *Fusaria* on the potato plant, H. W. WOLLENWEBER (*Mitt. K. Biol. Anst. Land u. Forstw.*, 1911, No. 11, pp. 20-23; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, p. 326).—The author states, as the result of his investigations, that *Fusarium subulatum* and *F. dimerum* are the most common forms, attacking all organs of the host plant. The former is said to be almost omnivorous. It is found late in August in the stems which remain green, as is true also of *Verticillium alboatrum*. Those which occur most commonly on the tubers are *F. solani*, *F. martii*, *F. cæruleum*, and *F. discolor sulphureum*.

Leaf roll of potatoes, O. APPEL and O. SCHLUMBERGER (*Mitt. K. Biol. Anst. Land u. Forstw.*, 1911, No. 11, pp. 13-15; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 32 (1912), No. 6-12, pp. 321, 322).—The authors investigated the statement that enlargement of the mother tuber is a characteristic of potato plants

affected with leaf roll. It was found that such enlargement took place also in case of potatoes not so affected, lasting for about the first 4 weeks after planting.

Successive crops from planting affected tubers were found to diminish both in number and size of tubers produced until in from 4 to 7 years the results became practically nil. A few escaped from this decline and showed a tendency toward normal products, which tendency is to be more fully tested. See also previous notes (E. S. R., 21, p. 243; 22, p. 347).

Bacterial rot of potato, O. APPEL (*Mitt. K. Biol. Anst. Land u. Forstw., 1911, No. 11, pp. 12, 13; abs. in Centbl. Bakt. [etc.], 2. Abt., 32 (1912), No. 6-12, p. 319*).—It is stated that a soft rot of potato tubers is caused by *Bacterium xanthochlorum*, also that this organism causes a blackleg disease of *Vicia faba* and a stem rot of *Lupinus mansi*. The author was not able to breed from *B. fluorescens*, which at 35° C. takes on pathogenic characters, a race corresponding to *B. xanthochlorum*.

Investigations with potato scab, A. BERNHARD (*Deut. Landw. Presse, 38 (1911), No. 27, p. 320; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, pp. 399, 400*).—Continuing previous investigations (E. S. R., 25, p. 245), the author compared results from the use of sulphur alone with those from its use in connection with lime. The all-sulphur treatment seemed the more effective.

The results obtained from planting seed potatoes affected with scab seem to forbid such use of infected tubers, while sound seed tubers in infected soil showed only sporadic infection.

Rice blight, J. L. HEWITT (*Arkansas Sta. Bul. 110, pp. 447-459*).—A form of rice blight characterized by the appearance of blighted heads at the time the grain is ripening is described.

Various theories have been proposed as to the cause of this trouble. The author has investigated a number of them and has arrived at the conclusion that it is due to some soil condition, probably an organic disturbance, and that whatever it is that causes the disease the plant suffers through injury to the root system.

An investigation of a number of plants from badly infected and slightly infected portions of the field and from a field which contained no blight showed that the roots were injured in proportion to the amount of blight. The blight appears to be associated with decaying plant debris in the soil, and the author proposes this as a working hypothesis to be further investigated.

For preventing the disease, the rotation of crops so as to have rice follow some crop that will leave the land free from decaying debris, plowing late in the fall, the burning of stubble, and such other means as are feasible to complete the normal decay or removal of all straw, weeds, and trash are suggested.

The beet nematode, L. FULMEK (*Monatsh. Landw., 4 (1911), No. 9, pp. 268-275, figs. 8; abs. in Centbl. Bakt. [etc.], 2. Abt., 32 (1912), No. 6-12, p. 314*).—This parasite was studied chiefly in its relation to the sugar beet. Its life history is discussed, also direct and indirect methods of combating its ravages, which also extend to several other cultivated plants. The development period is said to depend largely upon temperature.

Recommendations are made as to economical means for control of the disease, mainly along the following lines: (1) Rotation of crops so that no two which are favorable to the pest shall be planted within 4 years, (2) careful adaptation of fertilizers to soils, (3) shallower plowing, (4) avoidance of carrying infection by feet or tools, (5) removal of harboring weeds, and (6) the Kühn device of trap plants.

Further notes on the sooty mold of tobacco, E. INGLESE (*Bol. Tec. Cultiv. Tabacchi [Scagati], 10 (1911), No. 5, pp. 255-267; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 1, pp. 308,*

309).—In continuation of the author's investigations on the sooty mold of tobacco (E. S. R., 25, p. 455), a study was made of the effect of temperature on the formation of honeydew on the plants. Strong healthy plants about one-third grown were subjected to low and high temperatures by watering with hot and cold water, by placing ice around the plants, by injecting steam under bell jars, etc.

Aside from the temporary disturbance to the nutrition and transpiration of the plants, no injurious effect was noted, and it is concluded that sudden inequalities of temperature have no direct relation to the secretion of honeydew.

Some means for the control of *Thielavia* on tobacco, AIELLI-DONNARUMMA (*Bol. Tcc. Colliv. Tabacchi [Scafati]*, 10 (1911), No. 5, pp. 277-281; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, pp. 310, 311).—In experiments in the hybridization of tobacco it has been found that some crosses between the varieties locally known as Kentucky and Italia are quite resistant to attacks of *T. basicola*. One form, called type B, is not only of excellent character as to growth, productivity, and quality, but out of 66 plantations containing more than 320,000 plants, none was attacked by the fungus.

Diseases of cabbage and related crops and their control, L. L. HARTER (*U. S. Dept. Agr., Farmers' Bul.* 488, pp. 32, figs. 7).—Popular descriptions are given of a number of the more important diseases of cabbage and other cruciferous plants, with directions for their control. The diseases described are club root, nematode root knot, black rot, wilt, blackleg, soft rot, malnutrition, downy mildew, white rust, spot disease of cauliflower, leaf blight, powdery mildew and damping off.

Tomato leaf rust (*Bd. Agr. and Fisheries [London], Leaflet* 262, 1912, pp. 3, fig. 1).—A description is given of the leaf rust of tomatoes due to *Cladosporium fulvum*, which, it is said, is becoming a serious pest in parts of Europe. Spraying, if attempted, should be begun early so as to protect the plants, and when the plants are young half-strength Bordeaux mixture may be employed. When the plants are in flower and young fruit present, the use of a solution of potassium sulphid is recommended.

The enzymatic activity of some fruit fungi, D. BRUSCHI (*Atti. R. Accad. Lincei Rend. Cl. Sci. Fis., Mat. e Nat.*, 5, ser., 21 (1912), I, Nos. 3, pp. 225-230; 4, pp. 298-304).—After a brief account of observations made by others in this connection, the author reports his own studies with *Fusarium niveum*, *F. lycopersici*, and *Monilia cinerea*, in substance as follows:

The toxic activity of the 3 fungi studied upon the cells of such fruits as are attacked by them, as the plum, tomato, etc., is not proportional to the acidity of the fungus extract employed, and this toxicity is decreased by heating. None of these 3 fungi produces an enzyme capable of attacking cellulose, but *F. niveum* and *M. cinerea* secrete a pectinase which, by dissolving the middle part of the cell wall of fruits, produces rapid maceration. It is doubtful if this ability is shared by *F. lycopersici*. Each of these 3 fungi appears to develop an enzyme capable of breaking up nitrogen compounds into proteids and nonproteids.

Gummosis, F. A. WOLF (*Plant World*, 15 (1912), No. 3, pp. 60-66).—The author reviews the various theories that have been advanced to explain the phenomenon of gummosis, which is conspicuous in species of *Prunus* and *Citrus*. He claims that until the immediate cause of gummosis is demonstrated, it is reasonable to believe that enzymes play a very important rôle.

Apple tree anthracnose, H. S. JACKSON (*Oregon Sta. Circ.* 17, pp. 4).—The apple tree anthracnose due to *Glæosporium malicorticis* is described. This is one of the most serious fungus diseases of the apple in Oregon. It causes

cankers on the trunk and branches, the infection usually taking place in the fall of the year after the early rains. In addition to the cankers on the tree the fungus is sometimes found upon the fruit.

For the control of the disease the author recommends treatment based on orchard experiments which proved successful in reducing the amount of disease. The treatment consists of spraying with Bordeaux mixture, using a 4:4:50 solution, in the fall before the beginning of the rains, to be followed as soon as the fruit is picked by an additional spraying of a 6:6:50 Bordeaux mixture. It is believed that under ordinary conditions this treatment would be sufficient for controlling the disease, but where the fungus is very prevalent, an additional spraying should be given the trees, beginning somewhat earlier in the season. Where practical the cankers should be cut out before fully formed during the winter or early spring.

**The raspberry cane blight and how to control it, P. J. O'GARA** (*Off. Path. and Ent. Rogue River Valley, Bul. 4, 1911, pp. 8*).—The author gives a description of the raspberry cane blight caused by *Comiothyrium fuckelii*. This fungus attacks all the cultivated species belonging to the genus *Rubus*, and has also been observed on the wild species, as well as on roses and apples. The disease shows marked virulence with the black cap varieties of raspberries, and the Cuthbert, which is a red raspberry, suffers to a considerable extent. The varieties *Lucretia* and *Primus* of the dewberry are also badly injured.

The parasitism of the fungus has been demonstrated by inoculation experiments. For its control the author recommends the cutting out and removal of all infected canes, which should be burned, and after the field has been thoroughly cleaned, spraying in the fall before the rains begin with a rather strong Bordeaux mixture. An additional spraying should be given in the spring, about 3 applications being made before the blossoms appear. If roses are growing nearby they should also be given attention.

**Remedy for court noué** (*Rev. Sci. [Paris], 50 (1912), I, No. 14, p. 440*).—In a brief note it is stated that Bertrand has found that the application of either sodium chlorid, or sulphate or phosphate of ammonia, to grapevines at the rate of 150 gm. per liter, following the method adopted for the treatment of chlorosis with iron sulphate, has given good results in combating the court noué, which is characterized by the extreme shortening of the internodes of grapevines. The use of Thomas slag as a fertilizer, applied at the rate of 250 gm. per plant, has also given encouraging results.

**Combating leaf spot of grape (*Pseudopeziza tracheiphila*), A. BRETSCHEIDER** (*Wiener Landw. Ztg., 61 (1911), No. 5, p. 43; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, pp. 402, 403*).—Experiments were instituted by the author in order to test the hypothesis that this fungus lives through the winter in the veins of the fallen leaves, forms spores on these leaves during the winter, and infects the young leaves by means of these in the spring. Removal of the dead leaves seemed to make no difference in the spring infection. The author suggests that the fungus may winter in the vessels of the shoots. The use of sprays (1 per cent Bordeaux mixture, 1 to 2 per cent Cucusa, and 1 to 2 per cent Tenax) seemed to give equally beneficial results whether applied to the upper or the lower surface of the leaves.

**The mildew fungi and protection therefrom, O. Broz** (*Monatsh. Landw., 4 (1911), No. 3, pp. 71-78, figs. 6; abs. in Centbl. Bakt. [etc.], 2. Abt., 31 (1911), No. 11-15, p. 403*).—This is a somewhat popularized discussion of the so-called true mildew fungi (*Erysiphaceae*) in connection with suggestions for their control, the main reliance being placed on sulphur applied to the green foliage. Bordeaux mixture is recommended as a wash for trees and vines in 2 per cent

strength before leaf fall and 5 per cent in February or March before the young leaves appear.

**Experiments on the prevention of olive bacteriosis,** G. BELLINI (*Coltivatore*, 57 (1911), No. 32, pp. 431-433; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, p. 311).—The author describes the results of experiments carried on in Tuscany on the prevention of the spread of the olive bacteriosis, due to *Bacillus olea*.

In April, 1910, a hailstorm severely injured a large olive plantation. The small branches which had been injured by hail were cut from the trees, after which the limbs and trunk of the tree received a strong application of iron sulphate, consisting of iron sulphate 15 kg., lime 15 kg., and water 100 liters. At the same time the trees were sprayed with a dilute Bordeaux mixture composed of 0.8 kg. of copper sulphate, 0.8 kg. lime, and 100 liters of water. The bacterial tumors were cut out wherever observed and the cut surfaces treated with the mixture composed of iron sulphate and lime.

At the close of 1911 no evidence of bacteriosis was to be seen on any of the trees. The growth during the summer had been exceptionally vigorous, and the prospect for a large yield the next year was considered quite promising.

**Glaeosporiose of the Japanese persimmon,** S. ITO (*Bol. Mag. [Tokyo]*, 25 (1911), No. 296, pp. 197-201, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, p. 321).—In 1910 the author collected and examined a number of specimens of diseased fruit of the Japanese persimmon (*Diospyros kaki*). The present study was undertaken to determine the cause of this disease, which sometimes occasions considerable loss. Badly affected trees are known not to produce fruit for 3 years.

The symptoms of the disease may be recognized by the appearance in the middle or latter part of July of small spots on the unripe fruit. These are black, of varying sizes, from that of a pin head to from 1 to 2.5 cm. in diameter, circular or elliptical in outline, and frequently bordered by a yellowish brown ring. By the coalescence of a number of these spots a considerable area of the fruit may become involved. The affected fruits usually fall to the ground before ripening, and decomposition is hastened by other fungi. The fungus is also capable of attacking fruits in storage.

Inoculation experiments showed that the fungus can be readily transferred to ripe apples when the spores are inoculated on the wounded surface, but the reciprocal infection of the spores of *Glomerella rufomaculans* on green persimmons always gave negative results.

The fungus causing this disease is believed to have been hitherto undescribed, and the name *Glaeosporium kaki* n. sp. is given it.

**The cause of mottled leaf,** R. R. SNOWDEN (*Fla. Grower*, 6 (1912), No. 2, pp. 3, 4).—The author believes that he has traced several cases of malnutrition and incipient chlorosis or mottled leaf in orange and lemon trees to an excessive proportion of magnesia to lime in the soil. Ash analyses of leaves from healthy and sick lemon trees showed that in the leaves from the sick plants the percentage of potash was more than doubled and phosphoric acid increased by 11½ times, while lime was reduced about 50 per cent.

An examination of the soil about thrifty and diseased plants indicated that the magnesia-lime ratio for oranges should not fall below 1 part of magnesia to 2 of lime. For lemons the ratio of 1:0.84 was sufficient to maintain good color in the foliage. Below that figure the leaves became mottled or decidedly yellow.

**The bud rot of the coconut in Ceylon,** N. PATOULLARD (*Jour. Agr. Trop.*, 11 (1911), No. 124, pp. 315, 316; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 1, pp. 319, 320).—The author

quotes from a letter calling attention to the extreme sensitiveness of the coconut palm in Ceylon to injury to its leaves. It is said that the slightest prick or scratch to the tender part of the plant may start the disease. At first a brownish mark appears around the wound, and this gradually spreads until it reaches the center of the bud, where all the young leaves are destroyed.

There seems to be a connection between the appearance of the monsoon and the bud rot. At this time the rains and storms accompanied by the wind not only cause a rapid increase in the sap, but also result in much injury to the leaves, often breaking them off at the base. It is thought that these accidental injuries form one of the principal means of entrance of the organisms which cause the disease.

Attention is directed to the apparent resistance to injury of the coconut palm of the West Indies, where the leaves are often cut without evidence of the occurrence of the disease.

A new disease of lily of the valley, J. POLITIS (*Riv. Patol. Veg.*, 5 (1911), No. 10, pp. 145-147; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 2, p. 566).—The author describes a disease of *Concullaria majalis* in the botanic gardens of Pavia, the plants being attacked by *Botrytis vulgaris*. The fungus caused much injury to the vegetative parts of the plant and reduced the number of flowers to a considerable extent. Inoculation experiments demonstrated the parasitism of the fungus, as has been shown by other investigators.

*Loranthus sphaerocarpus* parasitic on *Dracæna*, F. ARENS (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 32 (1912), No. 20-25, pp. 564-587, pl. 1, figs. 6).—This is a detailed study of host and parasite in their anatomical and physiological relations.

The mycoplasma theory, J. ERIKSSON (*Biol. Centbl.*, 30 (1910), No. 1, pp. 618-623).—This is a brief account of previous studies on the subject by the author and some others (E. S. R., 26, p. 846).

Notes on some western Uredineæ which attack forest trees, G. G. HEDGCOCK (*Mycologia*, 4 (1912), No. 8, pp. 141-147; *abs. in Phytopathology*, 2 (1912), No. 1, p. 47).—An account is given of a number of species of *Peridermium* which attack conifers, especially in the Western United States. Among them are *P. filamentosum*, *P. pseudo-balsameum*, *P. harknessii*, and *P. montanum*. In addition descriptions are given of *Uredo (Melampsora) bigelovii*, the æcidial form of which occurs on larches, the other stages being very prevalent on willows in the West and Southwest. The presence of *U. (M.) medusæ*, a fungus common on poplar, is also noted.

The chestnut bark disease, N. J. GIDDINGS (*West Virginia Sta. Bul.* 137, pp. 209-225, figs. 12).—The blight or bark disease of chestnut due to *Diaporthe parasitica* is described. The history of the disease, description of its attack on chestnut trees, and its distribution throughout the United States are indicated, together with such measures as have been adopted by the U. S. Department of Agriculture and the Pennsylvania Chestnut Tree Blight Commission for its control. The author states that the disease has been reported from 3 rather widely separated localities in West Virginia, and recommendations are made to prevent its establishment and spread.

The progress of the fight against the chestnut blight (*Forest Leaves*, 13 (1911), No. 6, pp. 88, 89, figs. 6).—An account is given of the work of the Pennsylvania Chestnut Tree Blight Commission during 1911 in locating the spread of the chestnut blight in the State. The commission is carrying on laboratory work, determining the life history of the fungus. It is stated that the only practical method of destroying the spores is felling the trees and burning the bark and brush. As part of the State is badly infected, the commission is recommending the cutting and utilization of the timber as rapidly as possible.

The wintering and combating of the oak mildew, F. W. NEGER (*Thurand. Forstl. Jahrb.*, 62 (1911), No. 1, pp. 1-9, figs. 3).—Investigations are reported which indicate that the conidia of the oak mildew do not withstand the winter, but that the fungus is carried over by means of mycelium in the buds. For the control of the mildew in nurseries and elsewhere 1 or 2 sprayings with lime-sulphur are recommended, the number of applications to be determined by the virulence of the attack.

Preliminary notes on three rots of Juniper, G. G. HEDGCOCK and W. H. LONG (*Mycologia*, 4 (1912), No. 3, pp. 109-114, pls. 2; *abs. in Phytopathology*, 2 (1912), No. 1, p. 48).—The authors give descriptions of the gross and micro-chemical characters of 3 heart rots of junipers, also the distribution and damage done by each, and technical descriptions of the sporophores. The rots discussed are the white rot of *Juniperus virginiana*, due to *Fomes juniperinus*; yellow rot of *J. monosperma*, *J. utahensis*, and *J. sabinoides*, caused by *F. carlei*; and the stringy brown rot of *J. sabinoides*, *J. monosperma*, and *J. utahensis*, caused by *F. texanus*.

The nature of witches' brooms on *Pinus sylvestris*, F. ZACH and K. VON TUBBEUF (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 1, pp. 61-64, fig. 1).—A discussion is given on the nature and causes of witches' brooms occurring on the above and other species of pine.

The blister rust of white pine, A. D. SELBY (*Ohio Nat.*, 11 (1911), No. 4, pp. 285, 286; *abs. in Centbl. Bakt. [etc.]*, 2, Abl., 32 (1912), No. 6-12, p. 333).—This disease, known to have been found recently in two or three places in the United States, is thought by the author to have come from Germany with seedlings bought there. The blister rust has long been notable in that country on account of its preference for American white pine. The fungus (*Peridermium strobili*) is stated to be one stage of the rust of currants and gooseberries (*Cronartium ribicola*).

A disease of eucalyptus, R. AVERNA-SACCÁ (*Bol. Agr. [São Paulo]*, 12, ser., 1911, No. 7, pp. 471-482, fig. 1).—The author describes a disease of eucalyptus due to some species of Erysiphaceæ, and gives briefly the results of experiments for its control. The disease is most prevalent upon seedlings in the nursery, and spraying with potassium sulphate solution or the use of sulphur is recommended. In case of the presence of another disease, which is thought to be due to Peronospora, the addition of 3 per cent powdered copper sulphate to the sulphur is advised.

A new paint-destroying fungus, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1911, No. 8, pp. 325, 326, pl. 1).—The author describes a fungus that flourishes in great profusion on fresh paint in hothouses, its development being favored by a high temperature and constant humidity. It has also been observed occurring on paint elsewhere.

About a month or two after a hothouse has been painted, numerous small pale rose-colored specks appear. These increase in size and change to a purple or sometimes dark red color. Where white paint has been used the coloring is very conspicuous. When the fungus appears in abundance the paint is ruined, in one instance a loss of more than \$1,000 in a number of greenhouses being reported.

The presence of 2 per cent carbolic acid in paint was found to arrest the development of the fungus, and hydrogen peroxid would bleach or considerably reduce the red color without injuring the paint.

The fungus, which is believed to be undescribed, is named *Phoma pigmentivora* n. sp., and a technical description is given.

Experiments with lime sulphur against some fungus diseases, L. SAVAStANO (*R. Staz. Sper. Agrum. e Frutticol. Acireale, Bol.* 5, 1912, pp. 6).—Ex-

periments are reported in which lime-sulphur solutions were used to control the sooty mold on olives and oranges and the mildews of grapes, peaches, roses, oaks, etc.

The results show that lime-sulphur is efficient in controlling powdery mildews, exceeding in that respect sulphur as ordinarily applied. For the sooty mold the results were less definite, although the solution had value as an insecticide against the scale insects. For the rose rust it was inefficient.

**Notes on the preparation of copper fungicides**, G. CHAPPAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 12, pp. 353-360, figs. 3).—Directions are given for the preparation of various fungicides, and particular attention is paid to what are believed to be some of the essential facts relative to securing the most beneficial mixtures. The fungicides described are Bordeaux mixture, Burgundy mixture, Bordeaux mixture modified by the addition of neutral copper acetate, and fungicides containing soap, resin, oil, etc.

**The influence of tobacco smoke on plants**, H. MOLISCH (*Anzeiger K. Akad. Wiss. Wien, Math. Naturw. Kl.*, 1911, No. 2, pp. 20-22; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 31 (1911), No. 11-15, pp. 380, 381).—This is substantially a summary of reports already noted elsewhere (E. S. R., 26, p. 230).

### ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Further notes on the fruit-eating habits of the sage thrasher in the Yakima Valley**, Washington, C. H. KENNEDY (*Auk*, 29 (1912), No. 2, pp. 224-226).—In these further notes (E. S. R., 25, p. 150), the author states that the sage thrasher (*Orcoscoptes montanus*) did not appear in 1911 in numbers until the middle of August, thus was too late to attack blackberries and raspberries.

It was found that the omission of summer pruning to remove the extra foliage effectually protected nearly all of the bunches of Campbell Early grapes, the earliest variety to ripen, and concentrated the damage on the few that were exposed. It failed, however, to save the Tokays and other *Vitis vinifera* varieties, which began ripening 3 weeks after Campbell Early. In order to save the later varieties shooting was resorted to. "The small number killed and the speedy and complete disappearance of the species seemed to indicate that they are very local in their individual ranges, and that these were living altogether in the vineyard during their depredations."

The results of examinations made of 12 stomachs are reported.

"The omission of summer pruning is not a satisfactory method of saving the Campbell Early grapes as the later ripening involves a loss of about 30 per cent in value." The sage thrasher must be killed, and it is thought to be justifiable to shoot early enough to save the Campbell Early.

**The English sparrow as a pest**, N. DEARBORN (*U. S. Dept. Agr., Farmers' Bul.* 493, pp. 24, figs. 17).—This bulletin, designed to supersede Farmers' Bulletin 383 (E. S. R., 22, p. 549), describes means for aiding native birds against the English sparrow, the prevention of increase, and the best methods of effecting a reduction of their number. Additional directions for trapping and illustrated plans for the construction of traps are included.

**Starling (*Sturnus vulgaris*) in Chester County, Pa.**, T. H. JACKSON (*Auk* 29 (1912), No. 2, pp. 243, 244).—A flock of 30 or more individuals is reported to have been observed in December near West Chester.

**State of Washington laws relating to fish, oysters, and game, 1911** (*Olympia, Wash.: State Fish and Game Dept.*, 1911, pp. 116).—The laws relating to fish, oysters, and game are compiled and indexed in this handy form.

**Methods in insect photography.** W. C. O'KANE (*Jour. Econ. Ent.*, 5 (1912), No. 1, pp. 54-59, pl. 1).—This paper considers cameras and lenses, methods of lighting, posing the object, plates and developer, preparation for printing, and prints for half-tones.

**Some recent new importations.** C. L. MARLATT (*Jour. Econ. Ent.*, 5 (1912), No. 1, pp. 73-77).—Among the pests reported to have recently been introduced into the District of Columbia are the spruce aphid (*Lachnus juniperi*) on young spruce trees from Holland; a peach seed weevil (*Anthonomus druparium*), which is already a very serious pest in Europe from Siberia; a cecidomyiid, related to the Hessian fly, on lotus introduced as a fodder plant; the mango seed weevil (*Cryptorhynchus mangifera*); etc. The recently established pests mentioned include the European red tail (*Dasychiria pudibunda*) in New Jersey; the European smaller elm bark beetle (*Scolytus multistriatus*) in Massachusetts; the apple seed chalcis (*Syntomaspis druparum*) in New York; *Pulvinaria psidii*, *Hemodes howardii*, and the oriental scale pest (*Conchaspis agracci*), in Florida, etc.

It is stated that the investigations conducted by the Bureau of Entomology in Pennsylvania last year have demonstrated that the apple seed chalcis has spread in destructive numbers into orchards in that State. In some orchards at least one-third of the crop was destroyed by it.

**The insect enemies of trees and herbaceous plants in Uruguay.** A. BOUYAT (*Rev. Assoc. Rural Uruguay*, 40 (1911), No. 9, pp. 707-718, figs. 5; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 11-12, p. 2612).—The more important insects are here considered, including their life history, damage caused, methods of treatment, enemies, etc.

**Some apple insects of Connecticut.** G. H. LAMSON (*Connecticut Storrs Sta. Bul.*, 71, pp. 41-83, figs. 33).—A general account of insects and methods of control is followed by a brief popular account of the more common insect enemies of the apple with directions for combating them.

**What is the matter with the elms in Illinois?** S. A. FORBES (*Illinois Sta. Bul.*, 154, pp. 3-22, figs. 10).—This bulletin calls attention to a fatal affection of the American white elm, "now prevailing over a large part of southern Illinois, similar to and apparently identical with one which destroyed many elms in the central part of the State some 30 years ago. The character, extent, and cause of this destruction are such as to make it plain either that the elm must receive much more intelligent and assiduous care and treatment than it has heretofore had in this State, or that it must yield its place to some tree more hardy under conditions which it has itself failed to support.

"The elm disease (if such it may be called) now prevalent is first noticed from early summer to autumn—the leaves, first on the terminal twigs and later on the larger branches, ceasing their growth, turning brown, and finally falling. This loss is presently followed by the death of the branches themselves, as is shown the following spring when the rest of the tree leaves out. Usually the higher branches are first affected, but the whole top soon seems to blight, and in a year or two the tree is dead. Sometimes this process is greatly shortened, and scores of trees may perish within a single year after the first effects are noticed; and sometimes, on the other hand, it is greatly lengthened, extending through 5 or 6 years, and, in mild cases, even ending in recovery.

"Although there may be no definite sign of insect injury anywhere, it is most commonly the case that a thorough search of the trunk and larger branches will show patches of dead bark under which there are 2 or more kinds of burrowing insect larvæ, or borers. The roots of these trees are often affected somewhat as the branches are; that is, the smaller, terminal, so-called feeding roots

die and dry up progressively, the process extending to the larger roots and the base of the trunk." It is stated that the trees are not affected when growing under natural woodland conditions.

The author concludes that the injury is caused in part by drought and unnatural conditions of the tree, resulting in starvation, and in part by borers in the trunk, attracted by the unthrifty state. The former is perhaps the primary trouble in most cases. He considers free watering, fertilizing, and mulching of the soil to be necessary, at least in severe drought. Care should be taken in trimming trees and painting cut surfaces to prevent infestation; the use of various mixtures as repellents to borers is also suggested.

Brief descriptions are given, together with illustrations and the life histories, of the elm borer (*saperda tridentata*) and the reddish elm snout beetle (*Magdalis armicollis*), the insects chiefly concerned.

The cotton stainer (*Dysdercus suturellus*), W. D. HUNTER (*U. S. Dept. Agr., Bur. Ent. Circ. 149, pp. 5, figs. 2*).—*D. suturellus*, the only representative of the genus which occurs in the United States, is not of very great importance on account of its local restriction, but in Florida it is undoubtedly the most important cotton insect at the present time. Although it has a number of food plants, the only ones of special importance aside from cotton are the orange and the eggplant. Among the wild plants upon which this insect feeds are *Hibiscus* sp., as well as several others including guava, Spanish cocklebur (*Urena lobata*), and nightshade (*Solanum nigrum*).

The feasible means of control of this insect, in the order of their importance, are as follows: "(1) The prevention of the growth of the weeds upon which the cotton stainer breeds in great numbers; (2) the destruction, by means of kerosene and water, of the colonies of young bugs as soon as they make their appearance during the growing season; and (3) the attracting of the insects to small piles of cotton seed and their destruction when congregated in large numbers by means of hot water or kerosene."

Observations on the life history of *Enchenopa binotata*, I. MATAUSCH (*Jour. N. Y. Ent. Soc., 20 (1912), No. 1, pp. 58-67, pls. 2*).—This is an account of the eggs, larvæ, and nymphal forms of the membracid *E. binotata*.

Papers on Aphididæ.—Studies on a new species of Toxoptera, with an analytical key to the genus and notes on rearing methods, W. J. PHILLIPS and J. J. DAVIS (*U. S. Dept. Agr., Bur. Ent. Bul. 25, pt. 1, tech. ser., pp. 16, pl. 1, figs. 9*).—*Toxoptera mühlenbergiæ*, here described as new, first came under the authors' attention on July 24, 1908, at which time it was collected at New Paris, Ohio, on a species of *Muhlenbergia*. Later in the month it was found at Richmond, Ind. The species is closely related to the so-called green bug, having at first been mistaken for *T. graminum*.

Technical descriptions of its stages are presented. It has been found throughout northwestern and west-central Ohio and through east-central and northern Indiana, and probably occurs in any location in which *Muhlenbergia* flourishes. "Individuals of this species concentrate on the tender shoots and are rarely found on the tough leaves unless the plants are badly infested. They congregate in the curled central growing shoot. As this leaf expands and unfolds, they go to the younger curled leaf just below this. When in great numbers, they cause these tender shoots to wilt and turn yellow. Up to the present time *Muhlenbergia* sp. appears to be the normal host, though this aphid often goes to blue grass (*Poa pratensis*) when first hatched, since the young sometimes appear before *Muhlenbergia* has started growth. Colonies have been established on wheat, though they do not appear to thrive very well on it."

Approximately 10½ generations per year are indicated by the investigations here reported. "The period between birth and reproduction varies greatly,

being longest in the spring, when it varies from 15 to 22 days. In summer the shortest period was 6 days, varying from 6 to 13 days. In the fall it varies from 9 to 13 days. The average period throughout the season for the 13 individuals of the series of first born is 13.1 days.

"The length of life, like the period between birth and reproduction, varies greatly. During the spring, when lower temperatures prevail, the viviparous forms will live from 30 to 63 days, while in the summer they live from 16 to 29 days, and in the fall over 30 days. The average length of life throughout the season for the 13 viviparous individuals of the series of first born is 28.9 days.

"The sexes make their appearance about the first week in October. . . . A viviparous female may produce oviparous and viviparous females and males or she may produce only the sexes. Males and females reach maturity in from 15 to 23 days. The female will not oviposit without having first been fertilized and will live, under these conditions, for about a month, her abdomen becoming greatly distended with eggs. . . . When ready to oviposit, the females crawl down into the leaf sheath, which is usually separated from the plant stem for a part of its length and is somewhat curled, and deposit their eggs in this curled portion. The senior author has counted as many as 200 eggs in such a position."

A description of rearing methods followed is appended.

The life history of the alder blight aphid, T. PERGANDE (*U. S. Dept. Agr., Bur. Ent. Bul. 24, tech. ser., pp. 28, figs. 12*).—The author's long-continued observations of *Pemphigus acerifolii* Riley, inhabiting the soft or silver maple (*Acer dasycarpum*), and of *P. tessellata* Fitch, inhabiting the alders, have resulted in furnishing conclusive proof that these are "merely forms or series of one and the same species, which should now be known as *Prociphilus tessellata* (Fitch)."

"*P. acerifolii* issues during the early or middle part of April, or as soon as the young leaves appear, from winter eggs deposited the previous fall in cracks or under loose bark on the trunks of maples, on which return migrants from alders had delivered themselves of the true sexes. These young stem-mothers, after hatching from winter eggs, travel upward onto the branches and settle on the midrib of the underside of the young leaflets. Usually there is but 1, though frequently there may be 2, 3, or more on the same leaf, in consequence of which, as well as from the increasing irritation, the leaves thus infested exhibit a more or less marked tendency to fold or almost to 'double up' from the midrib downward.

"Under or within this protection or covering there may be observed numbers of larvæ and pupæ of different stages, up to 100 or more, in company with their mother, all of which, from early in June to the end of July, or until the supply of migrants has been exhausted, develop into winged migrants, without, however, leaving any larvæ behind to continue the series on the maple. These migrants fly then to the alders, which frequently are rather distant from the maples, and settle at once on the underside of the leaves of these shrubs, where they are soon engaged in depositing their larvæ, which surround them in a circle of about 20 to 100. These larvæ, after feeding for about an hour or so, move to the twigs, branches, or stems of the shrubs to start a new cycle of life for the species. Here a number of generations is developed, after which, from about the middle of September to the middle of October, numerous return migrants are developed, which fly back to the trunks of the maples to continue the cycle of life prescribed by nature."

The original host plant of this species is, therefore, the silver maple and not the alder, which is a secondary food plant. The most active among the carnivorous enemies are the larvæ of the lycænid butterfly *Feniseca tarquinus*, the larvæ of the lace wing fly *Chrysopa sicheli*, the larvæ and imago of 2 lady

beetles, *Hippodamia convergens* and *Adalia bipunctata*, the larvæ and imagos of an hemipteron (*Nabis*) *Pagasa fusca*, and the larvæ of various syrphid flies, which generally prove very destructive to these aphids and frequently exterminate whole colonies. As yet no internal parasites of this species are known. The ants which have been observed to construct tunnels or covers over these aphids are *Tapinoma sessile* and *Cremastogaster lincolata*; among those which simply gather honeydew are *Camponotus pennsylvanicus*, *Lasius alienus*, and *Monomorium minimum*.

Technical descriptions are given of the principal stages.

**Flour mill fumigation**, W. H. GOODWIN (*Ohio Sta. Bul.* 234, pp. 171-184, fig. 1).—This bulletin deals with the control of the Mediterranean flour moth, which appeared in Ohio in 1895 and has since spread through the medium of secondhand machinery, and more often secondhand sacks, to many of the flour mills of the State.

It is stated that by the constant watching of spouts, machines, conveyors, and bolters, together with a thorough cleaning of the whole mill once or twice a year, the pests may be almost kept in control. Detailed directions are given for the fumigation of mills with hydrocyanic acid gas, together with an account of the fumigation of 3 mills by the author.

The generation of heat by steam radiators in a mill in which maximum temperatures were reached, 141° F. on the first floor, 138° on the second floor, and 142° on the third floor and deck, indicate that heat can be used successfully for protecting flour mills and stored products against insects. All stages of the following named mill pests are stated to have been killed, even by the temperature attained on the lower floor: Rice weevil, granary weevil, saw-toothed grain beetle (*Silvanus surinamensis*), yellow mealworm, dark mealworm (*Tenebrio obscurus*), cadelle, confused flour beetle (*Tribolium confusum*), *Platyedema* sp., and Mediterranean flour moth.

The advantages favoring the use of high temperature are summarized as follows: "It is not dangerous to human life as are all of the other fumigants which are even fairly effective. There is no possibility of injuring floors, belts, or machines, and practically no danger from fire. The cost of a treatment, after the heating system is installed, is less than one-fiftieth of that of hydrocyanic acid gas fumigation. No time is lost in getting ready to use heat. The mill does not need to be shut down a week beforehand, and as most of the Ohio flour mills use steam power, the cost of a heating system would not be prohibitive. High temperature, as compared with other methods of treatment, by saving time and extra expense, will pay for the average heating system required in a flour mill in less than 5 years."

**Larvæ of a saturniid moth used as food by California Indians**, J. M. ALDRICH (*Jour. N. Y. Ent. Soc.*, 20 (1912), No. 1, pp. 28-31, pl. 1).—Saturniid caterpillars, apparently of the genus *Hemileuca*, are said to be collected by the Indians of the Mono Lake region from the leaves of the yellow pine (*Pinus ponderosa*). A smudge made beneath the tree causes them to drop and they are then killed and dried. The collection of this caterpillar for food appears to be an industry of considerable importance in the territory along the Nevada-California line.

**Some observations on the relations of ants and lycænid caterpillars, and a description of the relational organs of the latter**, E. J. NEWCOMER (*Jour. N. Y. Ent. Soc.*, 20 (1912), No. 1, pp. 31-36, pls. 2).—The author, who has made observations on the behavior of ants toward the larvæ of *Lycæna fulla* and *L. pseudargiolus piusius*, finds the larvæ of the latter species very generally attended in the third and fourth instars by the ants *Tapinoma sessile* and *Prenolepis imparis*, and occasionally by *Cremastogaster* and *Camponotus* (?).

This attention is due to the excretion by the larva, from a slit on the tenth body segment, of a liquid agreeable to the ants.

**Third report of director of fruit fly control, W. M. GIFFARD** (*Hawaii. For-ester and Agr.*, 9 (1912), No. 2, pp. 46-48).—It is stated that since the last report (E. S. R., 26, p. 758) the entomological department has succeeded in breeding the Mediterranean fruit fly from the fruit of carambola and brown persimmon. "In the latter case a single fruit was handed us, it having been the only one maturing on a newly introduced species." The author states that this fly has been bred from Chinese oranges, received from the Kohala district in the island of Hawaii.

**On the rearing of a Dermatobia hominis, A. BUSCK** (*Proc. Ent. Soc. Wash.*, 14 (1912), No. 1, pp. 9-13).—An account of the actual breeding of this oestrid parasite from man.

The infestation took place at Cabima, Panama, on May 29; only 1 cast skin was observed during the larval period; this was shed and pushed out nearly entire through the aperture in the skin on July 19; on September 9 the larva had attained full growth and left the arm, posterior end first. On being placed in a jar with wet sand it immediately burrowed down 2 in. to the bottom of the jar and pupated. The fly issued on October 23. The author states that a much greater period of sleep was necessary during infestation.

**The horse botflies in Argentina, F. LAHILLE** (*Bol. Min. Agr. [Buenos Aires]*, 13 (1911), No. 12, pp. 836-856, pl. 1, figs. 8; *Rev. Asoc. Rural Uruguay*, 41 (1912), No. 2, pp. 136-145).—An account of the life history, habits, and occurrence of *Gastrophilus nasalis*, the effect of its presence upon the host, prophylactic measures, etc., with notes on several other species.

**The genera Hypera and Phytonomus (Coleoptera, Family Curculionidæ) in America, north of Mexico, E. G. TITUS** (*Ann. Ent. Soc. Amer.*, 4 (1911), No. 4, pp. 383-473, pls. 10, figs. 12).—One species of *Hypera* (*H. punctata*) and 12 of *Phytonomus*, namely, *P. eximius*, *P. quadricollis*, *P. compius*, *P. diversipunctatus*, *P. seriatus*, *P. trivittatus*, *P. maritimus*, *P. castor*, *P. pubicollis*, *P. melcs*, *P. nigrirostris*, and *P. posticus* are recognized. Under each species the author gives a complete synonymic bibliography, original description, new descriptions of the stages so far as known, distribution, food plants, and life history. Maps illustrating the distribution are included.

**A revision of the genus Lasconotus, E. J. KRAUS** (*Proc. Ent. Soc. Wash.*, 14 (1912), No. 1, pp. 25-44).—The author recognizes 24 species as belonging to this genus of the coleopterous family Colydiidæ, 9 of which are described as new to science.

"Very little is known concerning the exact habits of the species. They are usually found associated with various scolytids inhabiting coniferous trees. Principal among these are *Pityophthorus* (*Tomicus*), and at least 2 species are found with *Phlæosinus*. Whether they are commensals or predaceous is not well known. The mouthparts, so far as I have examined, would indicate a predaceous habit, but even if so, whether they prey upon the scolytids themselves or the numerous other insects found in their galleries is still an open question. The larva is also so far unknown."

**The sugar cane beetle in Mauritius (Agr. News [Barbados], 11 (1912), No. 258, p. 90).**—It is stated that the beetle, which has recently become a serious enemy of sugar cane in Mauritius,<sup>a</sup> has been identified as *Phytalus smithi*. The fact that this species occurs in the Barbados, but is not of economic importance, is thought to be due to some very effective natural enemy.

**Papers on cereal and forage insects.—The false wireworms of the Pacific Northwest, J. A. HYSLOP** (*U. S. Dept. Agr., Bur. Ent. Bul.* 95, pt. 5, pp. 73-87,

<sup>a</sup> Bul. Agr. [Mauritius], 2 (1911), No. 19, pp. 475, 476.

figs. 6).—Up to within the past 5 years, except for a few scattering notices, the species of *Eleodes*, the larvæ of which are known as false wireworms, have been considered of only incidental if of any economic importance. Superficially the larvæ resemble the elaterid, or true wireworms, and on account of their resemblance and the similarity of their depredations in grain fields the two are often confused. On close examination, however, *Eleodes* larvæ are readily recognized by their structure.

Reports of their injury have been received or published from Nebraska, Kansas, and Washington. The results of 3 seasons' work in the Pacific Northwest are said to demonstrate quite conclusively that the false wireworms are among the most destructive insects to recently planted wheat and corn in that region, ranking second only to the true wireworms in importance.

The genus *Eleodes* is very closely confined to the Upper and Lower Sonoran Zones. The beetles do not fly and are therefore comparatively restricted in their distribution. The mass of the species occur in the Southwest, while several occur in the arid and semiarid regions of California, Oregon, Washington, and Idaho. A few species extend into the Carolinian Zone in Kansas, Nebraska, and Iowa, *Eleodes tricostata* having been collected as far east as Independence, Iowa.

Investigations conducted in the Big Bend region of Washington, briefly reported, are followed by technical descriptions of the egg, larva, pupa, and adult of *E. lecheri vandykci* and *E. pimelioides*. "False wireworms are known to feed on the seed of wheat, oats, and corn, on the tubers of potato, on the fleshy roots of sugar beet, and on several garden crops, as well as on a variety of dead organic matter. . . . The adult beetles have been observed feeding on the seed of wheat and corn, on the leaves of corn, on *Polygonum littorale* and other weed leaves, and on decaying vegetable matter."

The adults of *E. lecheri vandykci*, which emerge from hibernation in the early spring, soon deposit their eggs a few at a time in the ground, the female burrowing down through the soft dust to the moist soil below, usually to a depth of from 2 to 4 in. The average number of eggs laid appears to be about 150. The eggs hatch in about 18 days and the larvæ feed throughout the summer, usually on decaying vegetable matter, hibernate, and resume feeding as soon as the soil becomes warm enough the following spring. At this time they seriously injure spring sown grain. In June they transform to pupæ and early in July the newly emerged adults commence to appear. These adults feed during the remainder of the summer, congregating in large numbers under grain sacks, shocks, and any convenient shelter. They eat a small amount of grain and other vegetable matter and go into hibernation without mating and in the spring resume their activity. While the adults of the species here treated seem normally to live but 1 season, Blaisdell records keeping adults of *E. dentipes* in confinement for over 4 years.

Mention is made of a number of birds, horned toads or lizards (*Phrynosoma* sp.), and the garden toad (*Bufo* sp.), which have been found to feed upon the pest. A microgasterid parasite (*Perilitus* n. sp.) is said to have been reared from an adult *E. suturalis*, received from Belvidere, Nebr. A disease of the larva has also been reported from Nebraska.

The author recommends a modification of the farm practice as now followed. "Disk as early as the land can be worked and the apparatus is available, which will usually be in April. This will conserve the moisture fully as well as plowing. Then plow as late as possible; if the land has been well disked and the men and horses can be spared, it is well to defer this plowing to late July and early August. At this time the beetles are in the pupal, or, as they are commonly called, 'white-worm,' stage. They can not move through the ground as can the

active larvæ, but can merely squirm when irritated. The plowing, which should be deep to be effective, turns out great numbers of these pupæ, and they are either eaten by birds or killed by the burning sun. Many more are destroyed by being crushed or suffocated in the broken pupal cells. Aside from killing many *Eleodes* pupæ, this practice of late plowing the summer-fallow would greatly aid in weed eradication."

The results obtained through treating the seed with lead arsenate at the rate of  $\frac{2}{3}$  lb. per bushel, dissolved in water; strychnin sulphate, at the rate of  $\frac{2}{3}$  oz. per bushel, dissolved in water; and coal tar applied until the seed was all coated, then sanded until dry, were entirely negative, as all the plats, including the checks, were about equally attacked.

Technical results from the gipsy moth parasite laboratory.—IV. The chalcidoid genus *Perilampus* and its relations to the problem of parasite introduction, H. S. SMITH (*U. S. Dept. Agr., Bur. Ent. Bul. 19, pt. 4, tech. ser., pp. 33-69, figs. 8*).—During investigations in the spring of 1909 the author found a first stage larva (for which type of larva Wheeler has suggested the term "planidium") of *Perilampus hyalinus*, in the larvæ of *Limnerium validum*, an important parasite of the fall webworm. Later an adult was reared from a second planidium encountered in a pupa of the tachinid *Varichata aldrichi*, also an important enemy of the fall webworm.

During the following fall several thousand young fall webworm caterpillars were collected and reared to maturity. *Apanteles hyphantriar* Riley was found to be a fairly common parasite of the younger caterpillars, and *V. aldrichi* and *L. validum* of the older ones, as during the preceding summer. Examination of the puparia and cocoons of the parasites disclosed the fact that the planidia of *Perilampus* were even more common than they were during the preceding year. Maggots of the tachinid which had emerged from the caterpillar were examined and found to contain the planidia internally. "Dissection of the fully developed caterpillars revealed the fact that the tachinid maggots while still within the caterpillar contained these planidia, and going back still further to the younger caterpillars, the planidia were found to be present here irrespective of whether the caterpillar was infested by a primary parasite or not. Examination of a considerable number of the *Hyphantria* caterpillars showed that the planidium could be found in almost any portion of the caterpillar's anatomy, although they generally 'floated about' freely in the body cavity. Occasionally specimens attached to the larval organs, such as the alimentary canal or silk glands, were encountered. Further study of still younger caterpillars revealed the most interesting and significant feature of the whole life cycle, namely, the presence of the planidia upon the exterior of the caterpillars. These were apparently about to make their way through the integument to the interior in a search for suitable hosts upon which to complete their development."

Just how these planidia came to be located upon the skin of the caterpillars and how, when, and where the adult female *Perilampus* places her eggs, could not be ascertained. It is suggested that either the eggs are deposited upon flower heads or upon leaves of plants not in the immediate vicinity of the caterpillar colony, the planidia hatching from these eggs and being conveyed to the caterpillars by means of some intermediate carrier, or, which seems to be more plausible, that the eggs are deposited upon the food plant in the vicinity of a colony of the caterpillars. Dissection of adult female *Perilampus* indicated that the eggs are very numerous, as high as 250 fully developed eggs being found at one time.

Once the planidium becomes affixed to the caterpillar, it makes its way through the thinner portion of the integument found at the junctures of the segments, this passage being effected by means of its well-developed mouth

parts and specially armored head. From the data at hand it seems most likely that the time of attack upon the host larva follows at once upon the finding of another parasite within the caterpillar.

"Just what is the effect upon the caterpillar itself which is infested by *Perilampus* but which contains no primary parasite is a matter for conjecture. It seems likely, however, that its presence would not prevent the caterpillar from reaching its full development and it is probably only slightly inconvenienced if affected at all. . . .

"In case the planidium chooses a maggot of *Varielaeta* as its host, it remains endoparasitic until the puparium is formed. During the process of histolysis the *Perilampus* either orients itself in such a manner that it will be external to the tachnid pupa when pupation is completed, or it emerges from the pupa immediately after pupation; in either case, of course, it remains within the puparium. When parasitic upon this host the planidium, so far at least as the writer has been able to learn, normally hibernates in this stage and probably without nourishment."

In the case of the ophioline parasite *L. validum*, which emerges from the older caterpillars in the fall and hibernates as a larva in a silken cocoon, *P. hyalinus* appears always to remain endoparasitic throughout the winter. Dissections of hundreds of the puparia and cocoons brought to light the fact that whether the winter was passed ectoparasitically as upon tachnids, or endoparasitically, as upon *L. validum*, is dependent entirely upon the life cycle of the host parasite, that is to say, the planidium lives internally in its host until histolysis takes place, when it changes its mode of life from an internal parasite to an external parasite.

The other primary parasites of the fall webworm from which the author has reared *Perilampus* are 2 additional species of *Limnerium*, differing from *L. validum* in that they spin their cocoons within the skin of the caterpillar and emerge in the fall, and the braconids *A. hyphantriae* and a *Meteorus*, probably *M. communis*. In all 4 of these species the *Perilampus* completes its development at once. As yet the author has not actually found *Perilampus* to be a parasite of the large solitary ichneumonids *Anomalon ambiguum*, *Ichneumon cinetitorsis*, and *Mcclanichneumon* sp.

On the return of warm weather in the spring growth takes place gradually, following the completion of which, after a short resting period, ecdysis takes place. After settling down the second time the larva is likely to remain stationary for the rest of the larval (and the pupal) life pupation taking place as soon as it is full fed.

Discussions of the food habits of the adult, longevity and oögenesis, length of life cycle and influence of temperature, effect of parasitism upon the host, percentage of parasitism, superparasitism, description of a second species of *Perilampus* met with, the development of *Orasema viridis*, parasitic principally upon the harvesting ant *Pheidole instabilis*, as described by Wheeler (E. S. R., 20, p. 254), relationship of Eucharidae and Perilampidae, Rhipiphorus and other coleopterous parasites, host relations of the genus *Perilampus*, including a review of European rearing records of *Perilampus*, etc., and the economic aspects, follow.

**An internal parasite of Thysanoptera.** H. M. RUSSELL (*U. S. Dept. Agr., Bur. Ent. Bul. 23, pt. 2, tech. ser., pp. 25-52, figs. 11*).—This is a detailed report of studies made of the life history, habits, and economy of the parasite *Thripoctenus russelli*, a summarized account of which has been previously noted (E. S. R., 26, p. 858).

**On a new enemy of the grapevine cochylis.** F. PICARD (*Bul. Soc. Ent. France, 1911, No. 12, pp. 260, 261; Prog. Agr. et Vit. (Ed. l'Est-Centre), 32*

(1911), No. 52, pp. 773-775).—The author reports having found *Odynerus cherrieranus* to be an enemy of *Cochylis ambiguella* at Castries, in the Department of Hérault.

Two destructive Texas ants, W. D. HUNTER (*U. S. Dept. Agr., Bur. Ent. Circ. 148*, pp. 7).—The cutting or parasol ant (*Atta texana*) is known only from a limited area in south-central Texas, which extends from the Brazos River as far north as Waco to the Gulf, westward as far as San Antonio, and southward to the vicinity of Alice. "The ant is most common in the valleys of the Colorado, Guadalupe, Comal, and San Antonio rivers. In these situations it is evidently increasing in numbers from year to year. In many cases the nests occupy the land practically continuously for many miles up and down the valleys. . . .

"The habits of this insect have attracted great attention from scientists and others. The ants cut the leaves from trees and carry them to the nests. Each leaf is finely divided and made into small pellets. In this work the mandibles and legs of the ants are utilized. The small masses are placed upon the so-called fungus garden, where they furnish a growing medium for the growth of a fungus which furnishes the colony with food. As the supply of fungus is consumed the ants add to the old mass, so that eventually the nests are found to contain large spongy formations on the outer portion of which the slender threads of the fungus are growing. Evidently the ants exercise great care in preventing the contamination of the fungus garden by any but the sole species of fungus that is utilized. . . .

"The distance over which foraging expeditions take place may be 200 yds. or even more. Practically all species of plants seem to be suitable for food, although it is noticeable that only 1 species is attacked at a time. . . . Among cultivated crops, cotton, corn, fruit trees, sorghum, and many others are attacked. Among wild plants, forest trees are favored, and frequently the Spanish moss is used. The various species of oaks seem to be more or less immune, either on account of the texture of the leaves or the tannic acid they contain." In many cases the attack is concentrated on a single tree, which may be defoliated in a night. The damage to growing crops is frequently heavy and complaints have become more numerous in recent years on account of the greater abundance of the ants.

The best method of control is through the use of a potassium cyanid solution made at the rate of 1 oz. to 1 qt. of water. After carefully mixing this liquid, it should be poured into each of the openings, a quart to each opening. In experiments conducted by J. D. Mitchell it was found that the destruction of the entire colony followed after 1 or 2 applications in this manner. The use of carbon bisulphid is not practical on account of the very extensive excavations the ants make in the sand.

The agricultural or hillock ant (*Pogonomyrma barbatus molefaciens*) is of economic importance since it will not allow vegetation to grow in the immediate vicinity of its nest and because of the powerful sting which it uses on the slightest provocation. It occurs from the Brazos River westward. West of San Antonio it is replaced by closely allied forms and farther north, in Kansas and Nebraska, a distinct species (*P. occidentalis*) occurs. This ant is conspicuously a resident of open places and does not occur in wooded localities. "The mounds are 15 in. or more in diameter and are frequently covered with particles of earth or sand from beneath the surface which contrast strongly with the surrounding soil. The bare areas around the mound may be 10 ft. or more in diameter."

The most important enemy among the birds is the great-tailed grackle (*Megaquiscalus major macrourus*), commonly known as the jackdaw. Several

additional species are known to prey upon it and the horned toad or lizard (*Phrynosoma cornutum*) includes these ants as a part of its regular diet. The use of a solution of potassium cyanid, as recommended for the cutting or parasol ant, has been found to be a perfectly satisfactory method of destroying them. It is much cheaper and easier of application than in the case of the cutting ant on account of the fact that the underground portion of the nest is much less extensive, a pint of liquid being sufficient for even a large colony, though sometimes a second application may be necessary. Carbon bisulphid is also a good remedy and can be readily applied.

The ants of Guam, W. M. WHEELER (*Jour. N. Y. Ent. Soc.*, 20 (1912), No. 1, pp. 44-48).—This paper is based on a collection made by D. T. Fullaway of the Hawaii Federal Station, which is said to be sufficiently extensive to show that the ant-fauna of the little island is made up very largely of the "tramp" species that occur on the other small volcanic Pacific islands such as those of the Society and Hawaiian groups. Twenty-one forms are recorded, of which a subspecies, *Camponotus reticulatus fullawayi*, and a variety, *Prenolepis minutula atomus fullawayi*, are described as new to science.

The control of *Solenopsis geminata* in cinchona plantations, O. W. BARRITT (*Rev. Agr. [Santo Domingo]*, 6 (1911), No. 10, pp. 255-258; *abs. in Internat. Inst. Agr. [Rome]. Bul. Bur. Agr. Intl. and Plant Diseases*, 2 (1911), No. 6, pp. 1541, 1542).—The author recommends the application about the trunks of trees, 2 cm. (0.75 in.) above the soil, of a band from 3 to 5 cm. in breadth, consisting of 3 parts resin, 1 of soda, and 1 of tobacco decoction, and that a second band be placed 15 cm. above the first. For the destruction of ant nests the injection of a mixture of 2 parts resin, 1 of soda, and 1 of tobacco decoction is recommended.

Monograph of the gall-making Cynipidæ (Cynipinæ) of California, D. T. FULLAWAY (*Ann. Ent. Soc. Amer.*, 4 (1911), No. 4, pp. 331-380, pl. 1).—Fifteen genera are represented in California by 70 species, of which 18 are here described as new to science.

A key to the genera is included.

The red spider (*Tetranychus bimaculatus*) on cotton, E. A. MCGREGOR (*U. S. Dept. Agr., Bur. Ent. Circ.* 150, pp. 13, figs. 5).—This circular, which is based primarily upon work done at Batesburg, S. C., in 1911, but includes the results of observations made by G. A. Runner and H. F. Wilson during the 2 preceding seasons, presents a summarized account of present knowledge of the pest. Recent studies of additional material have led Banks to conclude that the name *T. glomeri* is synonymous with *T. bimaculatus*.

Experiments conducted with unmated female red spiders clearly proved that they are normally capable of laying eggs, which in turn hatch and develop into mature individuals. The female lays from 50 to 60 round, colorless eggs which hatch in the summer time in about 4 days.

The newborn spider molts in 2 days to the primary nymph. "In 2 more days (in summer) it, in turn, molts to the secondary nymph. The second nymphal stage lasts 2 days, at the end of which time, after molting, the fully formed adult emerges. Mating occurs at once and egg laying commences immediately afterwards. Thus, 1 generation requires in summer weather in South Carolina about 10 or 11 days. There are probably about 15 generations in an average year in that locality.

"The red spider colonies live on the under side of the cotton leaves, and their constant feeding causes blood-red spots to appear on the tops of the leaves. The effect upon the cotton plant is that the leaves drop, one by one, until usually the plant dies. The pest increases and spreads most rapidly in hot, dry

weather until (toward the end of July) several acres of a field may become badly damaged."

During the season of 1911, which was one of unusual drought, 17 generations were bred at Batesburg, S. C., between March 11 and November 5. "The influence of the weather on breeding activity is very noticeable. Hot, dry conditions greatly favor and hasten development, while cool, wet weather correspondingly retards it. A female laying normally about 6 or 7 eggs per day will often upon the occurrence of a very hot day, suddenly increase the number to 15 or even more eggs per day, or upon a chilly day may drop as suddenly to 1 or 2 eggs. . . .

"When cotton dies or becomes untempting in the late fall an exodus of red spiders from the cotton fields occurs in the effort to find more suitable food plants. At this time cotton mites may be easily found on a number of native and cultivated plants, prominent among which are cowpeas, tomato, Jamestown weed, ironweed, and cultivated violets. Most of these plants die after the frosts, but the violet remains somewhat green throughout the winter, and it is upon this plant, probably, that the vast majority of mites overwinter. . . . In all the red spider has been found in 1911 upon over 50 species of plants, including weeds, ornamental plants, and garden and field crops. Upon most of these the pest was only occasionally seen, but it was found commonly throughout the active season upon beans, cowpeas, dahlia, ironweed, Jerusalem-oak weed, Jamestown weed, okra, tomato, wild blackberry, and wild geranium."

In addition to the anthrocorid bug *Triphleps insidiosus*, 3 species of thrips (*Euthrips fuscus*, *E. occidentalis*, and *Scolothrips scarmaculata*) and several species of lady beetles are mentioned as predaceous enemies of the red spider.

The following remedial and preventive measures are recommended: Burn or grub out all weeds and underbrush about cotton fields and practice fall plowing so far as possible. Spray or destroy suspected violet plants in order to remove the sources of red spider infestation. Thickly sow cotton along margins of fields at points where infestation has appeared on former occasions, and plow these in about June 1, so as to intercept and destroy the invading mites. Maintain a careful watch of fields so that the first attacked plants may be detected, removed, and burned, thus preventing further spread. Apply one of the insecticides described to the infested portion of a field before occurrence becomes so general as to prohibit its use. Two applications should be made; the first to destroy the living mites, and the second, a week later, to kill the recently hatched individuals which were eggs at the time of the first spraying.

All of the following formulas have been found to give good results: Potassium sulphid 3 lbs. to 100 gal. water; flowers of sulphur 15 lbs. and fresh lime 20 lbs. to 100 gal. of water; miscible oil 5 gal. to 100 gal. of water; potassium permanganate, 16½ lbs. to 100 gal. water; miscible oil, 2½ gal. and black-leaf tobacco extract, 40 per cent; and flowers of sulphur, 28 lbs. and soft soap 14 oz. to 100 gal. of water.

**Fruit trees damaged by the red spider, R. E. TRUMBLE** (*Better Fruit*, 6 (1912), No. 10, pp. 27, 28, fig. 1).—The author reports the red spider to be the source of considerable injury in the Wenatchee Valley, Wash. In 1911 it was the most serious of the enemies of young fruit trees. "While its attacks are by no means limited to young trees, it does its greatest damage on 2- 3- and 4-year-old trees. Often one-half or more of the leaves will be so badly affected that they will fall from the trees, thus limiting the tree's nourishment and checking its growth."

**A mosquito larvicide disinfectant and the methods of its standardization, S. T. DARLING** (*Amer. Jour. Pub. Health*, 2 (1912), No. 2, pp. 89-93, fig. 1).—In the course of work by the Canal Zone sanitary department an efficient larva-

cide made from crude carbolic acid had been prepared, its particular advantages being cheapness, high larvacidal and germicidal powers, miscibility with water, and relative uniform composition. The work of destroying the algæ and mosquito larvæ in the Canal Zone requires an average of 250 bbls. per month, and a plant for its manufacture has been in operation for over 2 years.

To make the larvacide 150 gal. of crude carbolic acid of a specific gravity not greater than 0.97 and containing not less than 30 per cent tar acids "are heated in an iron tank having a steam coil with steam at 50 lbs. pressure. Two hundred lbs. of finely crushed and sifted common resin are dissolved in the heated acid and then 30 lbs. of caustic soda dissolved in 6 gal. of water are added. There is a mechanical stirring rod attached to the tank. The product is ready in a few minutes, yielding about 3½ bbls."

Its cost is shown to be 14.13 cts. per gallon. "The germicidal value when tested with *B. typhosus* in an aqueous emulsion of the larvacide has an R-D coefficient of from 2 to 5. As a mosquito larvacide it is used by spraying an aqueous emulsion (1 part of larvacide to 5 of water) over the surface and along the margins of pools and ponds or other mosquito breeding places so that the resulting dilution of the larvacide has a thin milky opalescence representing approximately a dilution of 1:5,000."

Anopheline larvæ are said to be slightly more resistant than *Culex* larvæ and all pupæ are more resistant than larvæ to the effects of this larvacide.

The author believes that the theory of Chick and Martin<sup>a</sup> that the removal of an emulsion of tar acids by bacteria is a process of adsorption and not a chemical combination and that disinfectants of this class possess superior efficiency because owing to this adsorption the bacteria rapidly become surrounded by the disinfectant in much greater concentration than exists throughout the liquid, holds true for algæ and protozoa. "When emulsions of larvacide are put up with large quantities of algæ, such as *spirogyra*, the larvacide loses its turbidity, 50 per cent being lost in some concentrations within 2 hours. Microscopic examinations fail to disclose a cause for this loss of turbidity."

A table which gives the hour after exposure at which anopheline larvæ either die or pupate shows that the efficiency of the larvacide will last for over 7 days. It also shows that when in contact with algæ for a period of 1 to 7 days, 70 per cent of the larvæ are destroyed within 48 hours. "The larvacide hastens pupation, and the algæ control shows that when larvæ are placed in contact with fresh algæ and fresh water the larvæ pupate naturally for several days; decomposition, however, sets in after 110 hours with the formation of a pellicle of bacteria and protozoa on the surface. The anaerobic conditions beneath the pellicle cause the death of algæ and larvæ."

### FOODS—HUMAN NUTRITION.

A report on the milling properties of Idaho wheat, J. S. JONES, H. P. FISHERN, and C. W. COLVER (*Idaho Sta. Bul.* 72, pp. 65, pls. 2).—Owing to the belief that northwestern grown wheats have a comparatively low milling value, which doubtless materially affects their price in certain markets, extended studies were made of the physical properties, weight per bushel, protein content, and milling value, as well as baking tests under laboratory and home conditions.

The Idaho wheat crop, it is pointed out, consists of a number of varieties grown under very varied conditions, only 3 or 4 being common to north and south Idaho, the two sections of the State where the contrast is greatest in

<sup>a</sup>Jour. Hyg. [Cambridge], 8 (1908), No. 5, pp. 698-703.

climate, soil, and methods of harvesting and marketing. Bluestem and Turkey Red are two well-known varieties useful for comparison between north and south Idaho conditions.

According to the authors' summary, it appears that "in weight per measured bushel, of all varieties encountered, Turkey Red, a hard winter wheat, stands highest; Red Russian, a soft winter wheat, stands lowest; indiscriminately between these two stand hard, semihard, and soft wheats of both winter and spring varieties. It would seem, therefore, that regardless of classification with reference to hardness, high, medium, and low weight per bushel is with Idaho wheat a variety characteristic.

"High, medium, and low protein content is likewise a variety characteristic, but it is far from uniform in any one variety. With Turkey Red it so happens that high average weight per bushel is associated with high average protein content; with Red Russian, low average weight per bushel with low average protein content. Nevertheless, within these or any other varieties the relative protein content of several samples can not with any degree of certainty be predicted from relative weights per measured bushel."

The protein content of Bluestem wheat and of Turkey Red wheat grown with irrigation in southern Idaho and with a rainfall of from 24 to 30 in. in northern Idaho is practically the same, while the protein content of Bluestem and of Turkey Red grown on the dry farms of southern Idaho is greater than when grown under irrigated conditions in the south, or under the humid conditions prevailing in the northern part of the State. "If we may generalize from this, within any one variety, on the basis of its protein content, the wheat of north Idaho, and the irrigated wheat of south Idaho, are practically of the same value for milling purposes. South Idaho dry farmed wheat is superior to either."

It is noteworthy, according to the authors, that in many homes where baking tests were made straight flour obtained from the wheats under consideration was given preference over high patent flours which can be secured in the local markets, "a point which perhaps indicates merely that color in flour is of less importance than heretofore it has been regarded in commercial grinding."

From the laboratory and home baking tests the following conclusions are apparently warranted, in the authors' opinion:

"The crude protein and gluten content of flour from any variety of wheat is a consideration of great importance in fixing its value for bread making purposes; a reasonable amount must be present to insure 'lightness.' But from several lots of flour representing as many different varieties of wheat, or from several lots representing but one variety, the best results in baking are not always obtained from those of greatest gluten content. Influence of ingredients used in 'setting' the sponge and the skill of the baker are considerations which should not be lost sight of. Our leading varieties, viz: Bluestem, Forty Fold, Little Club, Red Chaff Club, and Turkey Red, in the north; Bluestem, Colorado No. 50, Defiance, Dicklow, Gold Coin, and Turkey Red, in the south, at their best, are capable of yielding flour sufficiently rich in gluten to insure the finest quality of light bread. If the best variety of milling wheat is the one which most uniformly produces flour from which the most satisfactory results can be secured in baking, then, of all varieties grown in Idaho thus far examined, Turkey Red is the best."

**Wheat bread, É. FLEURENT** (*Le Pain de Froment. Paris, 1911, pp. 7+223, figs. 33*).—This handbook discusses the composition and nutritive value of wheat and wheat products, bread making, the modern baking industry, and other general questions.

**The effect of acids on bread fermentation**, A. J. J. VANDEVELDE and L. BOSMANS (*Separate from Verslag, en Meded. K. Vlaam. Acad. Taal en Letterk.*, 1911, pp. 261-286, *dgms.* 4).—From his study the author concludes that under the experimental conditions hydrochloric, nitric, sulphuric, propionic, butyric, and oxalic acid affect bread fermentation unfavorably, and that lactic, tartaric, and citric acid were without effect, while phosphoric, acetic, and benzoic acid had a favorable effect.

He also reports data regarding the effect of these acids upon electrical conductivity, catalysis, inversion, the development of micro-organisms, and other phenomena.

**Cotton-seed flour** (*Pure Products*, 8 (1912), No. 5, pp. 270, 271, *fig.* 1).—Information is summarized and suggestions made regarding the use of cotton-seed flour for bread making.

**Composition of Indian yams**, D. HOOSER (*Jour. Asiatic Soc. Bengal, n. ser.*, 7 (1911), pp. 57-62; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 16, p. 1027).—The results are recorded of analyses of 40 specimens of different species of yams (*Dioscorea*), including both cultivated and wild sorts.

The amounts of crude fiber and ash were much higher in the wild than in the cultivated varieties. Tests showed that an alkaloid (dioscorine) was generally present in the wild tubers (*D. darmona*, *D. bulbifera*, *D. pentaphylla*, and *D. alata*), but not in the cultivated tubers to any great extent. The alkaloid may be removed by soaking the tubers in water.

**The narra fruit**, H. VON GERARD (*Agr. Jour. Union So. Africa*, 3 (1912), No. 1, pp. 102-106, *fig.* 1).—The use of this wild fruit for food purposes is discussed. In addition to the use of the flesh, the author states that the pits are eaten like nuts and are used for making an oil.

**Some Asiatic milk products**, D. HOOPER (*Jour. Asiatic Soc. Bengal, n. ser.*, 7 (1911), pp. 63-67; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 16, p. 1027).—Analyses are reported of 2 samples of karut, a kind of dried skim milk cheese; chhana, a product obtained by acidifying hot milk; and dahi, a product made by fermenting buttermilk.

**A study of Turkish honey**, F. MUTTELET (*Ann. Falsif.*, 5 (1912), No. 42, pp. 191-194).—Details are given of the examination of 12 samples of Turkish honey.

**Marmalades**, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 233, 1912, pp. 25).—Details are given of the examination of 154 samples of marmalade collected throughout Canada. Of these, 14 samples contained glucose in amounts varying from traces to about 25 per cent.

**Vinegars**, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 235, 1912, pp. 31).—Data are reported regarding the examination of 151 samples of goods sold as cider, malt, and wine vinegars.

**The aromatic substances of foods and condiments** (*Pure Products*, 8 (1912), No. 5, pp. 264-270).—A descriptive summary.

**On the absorption and distribution of aluminium from aluminized food**, M. KAHN (*Biochem. Bul.*, 1 (1911), No. 2, pp. 235-244).—Tests, 3 in number, were made with dogs and covered from 52 days to 2 months. The general conclusions which were drawn follow:

"When biscuits baked with alum baking powder are fed in a mixed diet to dogs, aluminium passes in considerable amounts into the blood.

"Such absorbed aluminium circulates freely and, although it does not show a tendency to increase proportionately in the blood, it accumulates to some extent in various parts of the body. The bile contains a particularly large amount of aluminium under such circumstances. The pancreas, liver, muscle, and kidneys contain considerable amounts, while the brain and heart seem to

resist accumulation of aluminium. The long bones, under the conditions of these experiments, contained aluminium. The flat bone of the skull did not contain aluminium.

"Aluminium, when ingested in aluminized food under the conditions of these experiments, is absorbed in part and is excreted, to some extent, in both the bile and urine."

**The presence of arsenic in some vegetable food materials.** F. JADIN and A. ASTRUC (*Compt. Rend. Acad. Sci. [Paris], 154 (1912), No. 14, pp. 893-896*).—Arsenic was found in a large number of samples of vegetable products and fruits, fresh and dried, nuts, and edible fungi, the amounts ranging from 0.003 mg. per 100 in wild leek (*Allium polvanthum*) to 0.026 mg. per 100 in dried peas.

**Food inspection decisions** (*U. S. Dept. Agr., Food Insp. Decisions 143, 144, pp. 1 each*).—These decisions have to do respectively with the labeling of candied citron and the use of excessive amounts of water, brine, sirup, sauce, and similar substances in the preparation of canned foods.

**The sanitary regulation of the oyster industry.** F. P. GORMAN (*Amer. Jour. Pub. Health, 2 (1912), No. 2, pp. 77-84*).—From the data summarized the author concludes that the improvement of the shellfish industry involves "prohibition of the practice of floating oysters; prohibition of the use for food of shellfish taken from waters directly polluted with sewage, that is, within a certain distance of discharging sewers; careful sanitary regulation and supervision of the methods of handling and packing shellfish; [and] efforts to secure the removal of sewage pollution from the tidewaters where shellfish are grown, or at least the disinfection of all sewage effluents which enter tidewater."

The paper is followed by a discussion.

**The preservation of food.** ALICE RAVENHILL (*Brit. Columbia Dept. Agr. Bul. 37, 1912, pp. 19, figs. 10*).—This bulletin, which is one of a proposed series for the women's institute work, discusses methods of handling and keeping food, the preservation of foods in the home, and other similar questions.

**Southwest Africa camp food.** H. FISCHER (*Illus. Landw. Ztg., 32 (1912), No. 26, pp. 246, 247, figs. 3*).—Native foods are described and their uses discussed.

**How I lived on threepence a day.** F. J. CROSS (*London, 1912, pp. 124, charts 8*).—The author reports and discusses his experience living for a week on a diet costing 6 cts. a day, a sum which he states is comparable with that which many workmen's families have to spend per person for food. His general conclusion is that, with limited incomes, knowledge and care in the selection and preparation of food are absolutely essential if persons are to be well nourished. In addition, the volume, which is designed for the instruction of housekeepers, discusses such subjects as the relative nutritive value of different foods, suitable foods for working class households, and other questions.

The introduction is contributed by R. Hutchison.

**Cooperation and cost of living in certain foreign countries** (*U. S. House Representatives, 62. Cong., 2. Sess., Doc. 617, 1912, pp. 248*).—A large amount of data collected by United States consuls, regarding the cost of food, the work of cooperative societies, and the cost of living in certain foreign countries, is brought together, this material being preceded by a letter of transmittal by H. Wilson which gives a summary of the prices of common food materials in recent years in the United Kingdom.

**The school feeding movement.** LOUISE S. BRYANT (*Psych. Clin., 6 (1912), No. 2, pp. 29-43*).—An account of the origin and development of the movement

to provide food for school children, which summarizes a large amount of statistical and other data.

A bibliography is included.

**The training of the school dietitian, MARY S. ROSE** (*Psych. Clin.*, 6 (1912), No. 2, pp. 52-55).—Suggestions are made regarding the training required by a school dietitian, a profession which the author believes will become an important factor in education in boarding institutions and in the public schools of large cities.

**Administration of school luncheons, ALICE C. BOUGHTON** (*Psych. Clin.*, 6 (1912), No. 2, pp. 44-51, fig. 1).—An account is given of the school luncheon movement in Philadelphia, considered particularly as a business project.

**The economy of food, J. A. MURRAY** (*London, 1911, pp. XII+253, figs. 13*).—This popular treatise on nutrition discusses the physiology and chemistry of nutrition, the quantity of food required, the nutritive value and general properties of meats, vegetables, and other foods, ordinary diets, special diets, and similar questions.

**An explanation of hunger, W. B. CANNON and A. L. WASHBURN** (*Amer. Jour. Physiol.*, 29 (1912), No. 5, pp. 441-454, figs. 3).—In this paper the authors summarize and discuss hunger as distinguished from appetite, on the basis of their own investigations and the work of others. Of the two theories of hunger, the one that it is a general sensation with a local reference, and the other that it has a local peripheral source, they point out that the former has been the more widely accepted. The support for this theory, however, can be shown to be unsubstantiated.

In general, "hunger . . . is normally the signal that the stomach is contracted for action; the unpleasantness of hunger leads to eating; eating starts gastric secretion, distends the contracted organ, initiates the movements of gastric digestion, and abolishes the sensation. Meanwhile pancreatic and intestinal juices, as well as bile, have been prepared in the duodenum to receive the oncoming chyme. The periodic activity of the alimentary canal in fasting, therefore, is not solely the source of hunger pangs, but is at the same time an exhibition in the digestive organs of readiness for prompt attack on the food swallowed by the hungry animal."

Investigations into the jail dietaries of the United Provinces, with some observations on the influence of dietary on the physical development and well-being of the people of the United Provinces, D. MCCAY (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1911, No. 48, pp. 2+3+II+200*).—Continuing previous investigations (*E. S. R.*, 24, p. 568), an extended study was made of the dietaries in a number of Indian jails and experiments were carried on with reference to the digestibility of protein and carbohydrates of certain food-stuffs and combinations. In addition, the author studied the jail dietaries with reference to their salt content, the excretion of chlorids in the urine, the quantity of feces and urine excreted, the nitrogen content of the feces, and the effect of an increase or decrease in wheat consumed on the quantity of feces.

On an average the present diet made up of wheat, legumes, barley, vegetables, oil, and other similar vegetable foods, supplied 106.81 gm. protein per man per day, of which 72.81 gm. was digestible. The energy value ranged from 3,122 to 3,450 calories.

"Taking the whole year into consideration the dietaries of the jails of the United Provinces present an average daily intake of . . . 104.56 gm. protein per man, and are accompanied by an average daily absorption of . . . 69.50 gm. protein per man."

In the author's opinion "the defects of most of these diets are such as to lessen their nutritive value to a very serious extent, with the result that while,

according to their chemical composition, they appear to be superior to the English prison scales and even to most of the standard dietaries, in reality they are much inferior. The explanation for this will be found to be the low degree of protein absorption shown by the foodstuffs entering into the composition of the dietaries of the jails of the United Provinces."

Studies of digestibility showed a considerable range. The coefficient of digestibility of protein of ordinary jail wheat was found to be 67.1 per cent, a value considerably lower than that of first quality wheat. In general, the digestibility of the legumes studied was also lower than that of first quality wheat. The average digestibility of total carbohydrates in the jail dietaries was found to be 96.4; the carbohydrates of wheat, 96.5; and, in general, 92 per cent or over for the individual materials and combinations under consideration.

The author does not believe that the present dietaries contain an excessive amount of protein. "While acknowledging the force of the different arguments for the reduction of the level of protein metabolism, we have had sufficient evidence in our work in India to confirm us in the opinion that a liberal supply of absorbable protein is the all-important element of a diet, without which, no matter how plentiful the other constituents may be, physical fitness, capacity for work, and power of resisting disease can not be expected."

On the basis of the investigation a number of suggestions are made for improving the dietaries and for making them more economical. A series of 8 diets is given which are practically of identical nutritive values, and interchangeable, the particular diet in use at any stated time depending on the season of the year and on the food materials available.

In the section which deals with the relationship of food to physical development much detailed information is given regarding the food and physical condition of Brahmins, sikhs, Pathans, and other natives. In some cases the diet is principally vegetarian; in others vegetables and dairy products are used; while in others a mixed diet is followed.

In general, it is the author's opinion that the more generous the diet the more satisfactory the physical condition and general well-being. "From the facts we have been able to collect with regard to the inhabitants of the United Provinces and martial races of the plains, there would appear to be abundant evidence that, other things being equal, diet is the all-important factor in determining the degree of physical development and general well-being of a people, and that with a low level of nitrogenous interchange deficient stamina, morally and physically, must be expected."

**The effect of a strictly vegetable diet on the spontaneous activity, the rate of growth, and the longevity of the albino rat, J. R. SLOAKER** (*Leland Stanford Jr. Univ. Pubs., Univ. Scr., 1912, pp. 36, pl. 1, figs. 15*).—Using 2 groups of young rats the same age and as nearly as possible of the same parentage, the author studied the effects of a vegetable diet in comparison with the same diet plus animal food.

According to his conclusions, the omnivorous feeders were more active and voluntarily did much more work than the rats on a vegetarian diet, the average ratio of efficiency being 7.5:1. The females surpassed in activity the males of the same group, the difference being greater with the omnivorous rats than with those receiving the vegetable diet. The difference was not very noticeable until the experiment had proceeded 2 or 3 months or until about one-fifth of the total life of the rats on the vegetable diet had been lived. "One can not conclude, therefore, that a diet used for a few weeks is not injurious if no bad results occur during that time.

"The total work accomplished by the vegetarians during their life was performed by the omnivorous rats when but 20.9 per cent of their lives had been lived.

"The vegetarian rats age much earlier in life, it requiring almost half their lifetime to perform the last one-eighth of their life's work, as compared to three-tenths for the omnivorous rats.

"The growth of the vegetarians was greatly retarded. The ratio of maximum weights was a 1.62:1 in favor of the omnivorous feeders.

"The effect on general conditions of the body was most overwhelmingly in favor of the omnivorous. The vegetarians were frail, weak, and showed extreme lassitude and indifference. The omnivorous were the reverse in all these respects.

"The average life of the omnivorous was 1.020 days, that of the vegetarian 555 days. This was a ratio of 1.84:1.

"The control rats in stationary cages lived longer than the exercised rats of the same group.

"All of the omnivorous rats surpassed the greatest age attained by the oldest vegetarian rats.

"From numerous observations and experiments of other investigators on man we would infer that similar results would obtain if he were subjected to similar conditions throughout his lifetime."

**Effects of coffee drinking upon children.** C. K. TAYLOR (*Psych. Clin.*, 6 (1912), No. 2, pp. 56-58).—Statistics were obtained from 464 children with respect to coffee drinking, and physical measurements were made, as well as observations regarding the character of their school work.

It was found that about 29 per cent of these children drank no coffee, 46 per cent a cup a day, 12 per cent 2 cups, 8 per cent 3 cups, and the remainder 4 or more cups a day. The statistics obtained, according to the author, "are hardly sensational," but he believes that "if such differences exist between the mental ability, as shown by lesson work, and behavior, as shown by conduct marks, of those drinking and those not drinking coffee, this beverage must have some unwholesome effect upon children that it does not have upon adults."

As regards physical measurements, "the children concerned in this test who drank coffee regularly averaged from 1½ to more than 4 lbs. less in weight, from ½ in. to more than 1 in. less in height, and all the way to 3 lbs. less in hand strength than those who never drank coffee. These differences may not be startling, but it is evident that there are differences.

"As a conclusion, then, to this very brief paper, the writer would say that it seems likely that the regular drinking of coffee by children has an effect which is certainly not beneficial, that indeed it seems to make children less 'fit' physically as well as mentally than those who do not use coffee. If this be true, then some support is given to the modern movement which advocates the substituting of cocoa or chocolate for coffee as a beverage for children."

**The cleavage of xanthin and caffein in the human body.** W. LEVINTHAL (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 4, pp. 259-279).—From an experimental study of the subject the conclusion is reached that very probably the xanthin metabolized by man is excreted quantitatively without breaking the purin ring, the greater part being oxidized to uric acid and the small remainder leaving the body unchanged.

**On fat absorption.** W. R. BLOOR (*Jour. Biol. Chem.*, 11 (1912), No. 4, pp. 429-434).—The results obtained in experiments with dogs show quite conclusively, according to the author, "that none of the isomannid esters had passed unchanged into the chyle, although considerable quantities had been digested and absorbed." This result, which is in accord with work which has been

previously reported, "emphasizes the probability that readily saponifiable fatty acid esters do not escape saponification under the favorable conditions in the normal intestine (excess of lipase, rapid removal of the products). Whether fatty substances of any kind may pass into the chyle unchanged remains to be proven."

**The chemical analysis of the ash of smooth muscle**, E. B. MEIGS and L. A. RYAN (*Jour. Biol. Chem.*, 11 (1912), No. 4, pp. 401-414).—Experiments are reported and data summarized. According to the authors, the facts at present known point to the following conclusions in regard to smooth muscle:

"The fibers of this tissue are not surrounded by semipermeable membranes.

"Most of the water of the smooth muscle fibers is held by the colloids of the living tissue as organic water.

"Most of the potassium, phosphorus, sulphur, and magnesium, which appear in the ash of smooth muscle, are present in the living tissue in a nondiffusible form."

**Metabolism during mental work**, A. LEHMANN (*Umschau*, 16. (1912), No. 19, pp. 390, 391).—A brief summary of a paper presented at the Congress of Experimental Psychology in Berlin. The mental work in the experiments consisted in adding simple numbers or in committing to memory syllables arranged without reference to meaning.

The author concludes that under controlled conditions such mental work caused an increase of carbon dioxide excreted which is directly comparable with that noted in the case of physical work. The increased carbon dioxide production was proportional to the severity of the mental work as measured by attention.

**A new ice chest**, C. ZELMANOWITZ (*Biochem. Ztschr.*, 39 (1912), No. 1-2, pp. 151-154, fig. 1).—An ice chest designed for laboratory use is described in which a current of air is driven into the ice chamber and kept in continuous circulation by means of a small electric motor. The front of the ice box contains a number of small doors, the object being to lessen the rise of temperature when articles are placed in it or removed. Even when due allowance is made for the cost of the motor and power, the ice chest has been found more economical than one cooled with ice in the usual way, according to the author.

[The ideas embodied in the construction of this ice chest might prove useful in ice chests for institution use or for some similar purpose.]

## ANIMAL PRODUCTION.

**The vitality of reproductive cells**, L. L. LEWIS (*Oklahoma Sta. Bul.* 96, pp. 3-47, figs. 7).—This contains a description of the reproductive glands of horses, cattle, swine, and mules, and a report of experimental work on the vitality of spermatozoa and ova, being a continuation of earlier work (see page 274).

Measurements of the sperm cells from horses, cattle, and swine are given, showing that there was but little variation in size for different individuals of the same species. In a number of experiments in keeping semen of stallions at temperatures from 12 to 52° C., the high temperatures were found to be quickly fatal to the sperm cells. Keeping the semen in rubber and pig bladder, or adding water or other materials, reduced the vitality. Semen-like material from male mules contained no sperm cells.

"Under experimental conditions the vitality of the sperm cells from the boar continues approximately 15 to 25 hours after the semen is collected. The length of time depending upon the temperature at which the semen is kept, and the vigor and physical condition of the animal used in the experiment. Temperature has much the same effect on the vitality of the semen from the

hog as it has on that collected from the horse. . . . Semen from different males varies greatly in its vitality under laboratory conditions. This difference is sometimes so noticeable as to indicate the probability of poor breeding qualities."

To determine the vitality of sperm cells in the female, sows were killed at varying lengths of time after service. Of the 19 sows bred and killed the sperm cells were found dead in 80 per cent of the cases where a period of 16 hours or more had elapsed. In one case the live cells were found after a lapse of 22½ hours, and in 2 cases after a lapse of more than 40 hours. Vitality tests with the sperm of horses showed it to be very short-lived either in the mare or under abnormal conditions.

To learn of the effect of continuous service, a heavy draft stallion was used once each day. The number of sperm cells present in the semen in his first service was 131,750 per cubic millimeter, and live cells were found 95 hours after service when kept at from 31 to 35° C. After the ninth service there were only 5,840 sperm cells per cubic millimeter, and the vitality of the cells was less than one-half as compared with those of the first cells. Other experiments for 11 days' and 18 days' consecutive service showed that the vitality was reduced from the first to the last service. Chemical analyses of the sperm cells are given.

Experiments were also made to determine the time of the rupture of the Graffian follicles and the vitality of the ova in sows. "If the hog was killed early in the period of heat the follicles showed perfect and unruptured, while those from hogs killed a few hours later showed the follicles ruptured. A few sows were killed when not in heat, and in none of these were the follicles found well developed or in condition to liberate the ovum, neither did they show any signs of the recent escape of the ovum from the organ. Variations from the normal no doubt do occur, but it is safe to assume that in the great majority of cases the follicles do not rupture before 30 hours after the period of heat begins." Whenever sows were bred out of heat no results were obtained unless it occurred within 1 day. Post-mortem examinations after breeding out of heat indicate that the ovum and sperm cells soon lose their physiological activity after they become separated from the ovary and testes.

"The vitality of the reproductive cells of the hog is only a few hours. In most cases the ovum appears to lose its power of being fertilized within 48 hours, and the sperm cell does not appear to possess much, if any, greater vitality. . . . The ovum (in hogs) is not liberated from the ovary until the last part of the period of heat."

**Artificial insemination**, L. L. LEWIS (*Oklahoma Sta. Bul. 93, pp. 9-13, figs. 5*).—A revised edition of a bulletin previously noted (*E. S. R., 17, p. 1193*), with a brief report of experiments which are more fully noted in Bulletin 96 (see page 273).

**Is the control of embryonic development a practical problem?** C. R. STOCKARD (*Abs. in Science, n. ser., 35 (1912), No. 907, p. 788*).—This is an abstract of a paper read before the American Philosophical Society, 1911, which discusses the factors which cause embryonic deformities in man and animals. These may be distinguished as those caused by the embryo developing in an unfavorable environment, and those in which the germ cells of both parents may have been defective.

The results of experiments with guinea pigs have shown that when put into a state of chronic alcoholism and mated together or with normal individuals, the resulting offspring were greatly affected, showing that the paternal germ cells are affected by the alcohol and produce abnormal offspring. It is sug-

gested that there may be some means of controlling the chemical environment of the developing germ.

On Mendelian dominance, A. R. MOORE (*Arch. Entwickl. Mech. Organ.*, 34 (1912), pt. 1, pp. 168-175, figs. 9).—In support of a hypothesis, previously noted (E. S. R., 23, p. 778), the author cites a number of experiments with invertebrates by which incomplete dominance can be explained on biochemical grounds.

"According to our hypothesis that the substances underlying the formation of dominant characters obey the laws governing enzym reactions, we should expect these reactions to go forward at a slower rate in the heterozygote than in the pure dominant because the former contains but one-half the amount of enzym to be found in the latter."

A simplified method of calculating frequencies of occurrence from a large number of unequal probabilities, A. G. MCKENDRICK (*Biometrika*, 8 (1912), No. 3-4, pp. 413-419).—This biometric method of determining whether the distribution is regulated by laws of chance or by other factors is illustrated by applying it to a study of the recurring attacks of disease in epidemics.

Factors affecting the secondary sexual characters, E. STEINACH (*Zentbl. Physiol.*, 24 (1910), No. 13, pp. 551-560; 25 (1911), 17, pp. 723-725; *Jour. Amer. Med. Assoc.*, 58 (1912), No. 7, p. 484).—Testes and ovaries of rats and guinea pigs were transplanted into early castrates of the same and the opposite sex. The tissues maintained their integrity and exerted an influence on the sex characters. Neither the somatic nor the psychic secondary traits were fixed in the individual. They developed under the domination of the respective glands which were present and functionally active.

Contribution to the study of experimental determination of sex, I. BONAZZI (*Arch. Ital. Biol.*, 56 (1911), No. 3, pp. 433-447, figs. 8).—Following the methods used by Ducceschi and Tallarico<sup>a</sup> an orchitoxic serum obtained from sheep was injected into rabbits. It was without apparent influence on the sex ratio but had a tendency to produce sterility and abortion. This opinion was confirmed by an examination of the ovarian tissue of the treated rabbits.

Another sex-limited character in fowls, A. H. STURTEVANT (*Science, n. ser.*, 33 (1911), No. 844, pp. 337, 338).—A preliminary report of experiments in crossing Columbian Wyandottes and Brown Leghorns.

An experiment dealing with sex-linkage in fowls, A. H. STURTEVANT (*Jour. Expt. Zool.*, 12 (1912), No. 4, pp. 499-518, figs. 4).—A continuation of work noted above, and summarized as follows:

"There is a sex-linked factor carried by the Columbian Wyandotte—an inhibitor for red in the plumage. This breed probably also carries another sex-linked factor, an inhibitor for red in the neck. It apparently carries a pattern factor inhibiting the breast color, and, in the female, the stippled back of the Brown Leghorn. The silver-gray color is probably epistatic to the Jungle fowl or brown color. The White Wyandotte is a silver-laced breed with a color producer dropped out.

"An attempt is made to explain three sets of phenomena, in fowls, in canaries, and in *Agilia tau* respectively, as cases of partial sex-linkage. Using this explanation, it is argued that the sex formula for birds and Lepidoptera is probably: ♂, MM, FF: ♀, Mm, FF. The case of the dwarf guinea pig is explained as perhaps representing partial sex-linkage in a form where the male is heterozygous for sex."

A bibliography is appended.

<sup>a</sup> *Arch. Fisiol.*, 1 (1904), p. 604.

The correlation of body weight and egg production in fowls, G. WIENINGER (*Wiener Landw. Ztg.*, 62 (1912), No. 26, pp. 320, 321).—Some of the results obtained from a study of the correlation between the weight of the hen and of the eggs laid are summarized in the following table:

*Average weight of hens and of eggs laid per hen.*

Breed.	Average weight of hen.	Average total weight of eggs per year.	Average weight of 1 egg.
Italian partridge:	Kg.	Kg.	Gm.
General average of the flock for 7 years.....	2.259	7.865	58.6
Average of 5 best layers.....	2.125	8.730	57.8
Average of 5 poorest layers.....	2.409	6.849	59.5
Golden Wyandotte:			
General average of the flock.....	2.549	8.641	57.3
Average of 5 best layers.....	2.476	10.245	57.2
Average of 5 poorest layers.....	2.650	6.743	57.1

Hybridization of canaries, A. R. GALLOWAY (*Biometrika*, 8 (1912), No. 3-4, pp. 435, 436).—An explanatory note concerning the author's paper, previously noted (*E. S. R.*, 22, p. 172).

[The significance of the chemistry of the proteins in animal nutrition], T. B. WOOD (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 23 (1911), pp. 84-93).—The aim of this article is to show the practical value to the stock feeder of the new points of view of the physiological chemists in regard to proteins that the value of a protein may vary greatly according to the amino acids into which it may be decomposed. The quantity of protein necessary for an animal varies considerably, being smaller the nearer the composition of the protein of the feed approaches that of the protein of the animal tissues. As farm stock nearly always received a mixed diet, the constituents of which can be varied within certain limits, these mixtures are ordinarily successful because the protein of the several ingredients of the diet are complementary to each other.

Experiments are cited to show that the successful stock feeder of the future must know something of the nature of the amino acids contained in the proteins of the different feeding stuffs.

Starch values and fodder units, O. JENSEN (*Milchw. Zentbl.*, 41 (1912), No. 6, pp. 161-165; *Molk. Ztg. Berlin*, 22 (1912), No. 19, pp. 217, 218).—This gives the author's views regarding the formulation of rations by means of starch values and fodder units.

Starch values and fodder units, trans. by J. H. MONRAD (*Hoard's Dairyman*, 43 (1912), No. 15, pp. 586, 587, 590).—This is a translation of the above.

[Alpine pasture lands], E. MARCHETTANO (*Separate from Bol. Assoc. Agr. Friulana*, 1911, pp. XV+150, map 1; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 2, pp. 514-521).—A general statistical article on Alpine pasture lands in the Province of Udine, Italy, with special reference to the work of the agricultural association of Friuli.

The rate of evolution of hydrocyanic acid from linseed under digestive conditions, S. H. COLLINS (*Proc. Univ. Durham Phil. Soc.*, 4 (1911-12), No. 3, pp. 99-106, figs. 2).—Linseed meal was digested at temperatures approaching those of animal life, and the hydrocyanic acid and other volatile products removed by a stream of inert gas. The amount of hydrocyanic acid produced depended upon the amount of cyanogenetic glucosid, the amount of enzym, the temperature, and the degree of acidity of the liquid, as well as on the presence or absence of a number of other substances. The conclusion is

reached that in normal health, the acidity of the stomach is too high for the production of hydrocyanic acid from linseed, but abnormal circumstances may cause its production.

"The above research explains the paradox that while a farmer considers linseed one of the safest cattle foods and uses it for calf rearing, yet the chemist shows that linseed in the laboratory readily gives off prussic acid, one of the most deadly poisons.

"Further, this research suggests a possible explanation of certain rare and puzzling cases of cattle poisoning. Should a linseed, rich in cyanogenetic glucosids, be fed to a beast suffering from indigestion of such a peculiar character that the food was not rendered acid, then prussic-acid poisoning might set in. Such a combination of circumstances must be very rare, but is by no means impossible."

**The Pandacan forage factory, Z. K. MILLER** (*Philippine Agr. Rev.* [*English Ed.*], 5 (1912), No. 3, pp. 133-141).—Brief reports are made on drying and storing corn, testing grain rations, and artificially drying forage.

Experiments made in crushing and drying grasses and green forage plants showed that the cost was too high to be practicable. The experiments will be repeated when a more economical dryer is obtained, as artificial drying of forage is a necessity during the rainy season, or until irrigation systems can be installed so that forage plants can be grown in the dry season.

**Cooked yeast as a feed for cattle, J. PAECHTNER** (*Wehusechr. Brau.*, 29 (1912), No. 16, pp. 225-227, fig. 1).—Methods of utilizing waste yeast from breweries as a feed for live stock are discussed, and a contrivance for cooking fresh yeast by means of a coiled steam pipe is described.

**Cattle breeding, II, WERNER** (*Die Rinderzucht. Berlin, 1912, 3. ed., rev. and enl.*, pp. XII+756, pls. 128, figs. 106).—In this revision many changes have been made, especially in the sections devoted to breeding and feeding.

**The organization of the bovine breeding societies in France, M. VACHER** (*Jour. Soc. Cent. Agr. Belg.*, 59 (1912), No. 6, pp. 153-162).—This discusses the nature of the cattle breeders' associations in France and the results which they have accomplished.

**The origin and ancestry of Norwegian cattle, J. FROST** (*Milchw. Zeitbl.*, 41 (1912), No. 4, pp. 117-121).—According to the author's views, which are similar to those of Dettweiler (*E. S. R.*, 26, p. 166), the first domesticated cattle and horses in Norway were brought from Freisland or Jutland in Neolithic times, are of the same origin as the Finnish stock, and are black or black and white in color. Red cattle were introduced at a later period and are of German origin.

**The important blood lines of the black and white East Friesian cattle, GROENEWOLD** (*Arb. Deut. Gesell. Züchtungsk.*, 1912, No. 13, pp. 101, tables 10, pls. 17).—This contains pedigrees, milk records, photographs, and other data of many noted animals of this breed.

**The Harz cattle, GEORGS** (*Mitt. Deut. Landw. Gesell.*, 27 (1912), No. 19, pp. 276-279).—A description of the characteristics of the cattle in the region of the Harz Mountains, and a discussion of the methods of feeding, breeding, and managing.

**Imported stock and their progeny, M. A. O'CALLAGHAN** (*Agr. Gaz. N. S. Wales*, 23 (1912), Nos. 2, pp. 93-108, pl. 1, figs. 11; 4, pp. 315-332, pls. 4, figs. 13).—Milk records and other data of cows imported to New South Wales, belonging to the Shorthorn, Ayrshire, Jersey, and Guernsey breeds, are reported.

**Caracul sheep, H. KRAEMER** (*Mitt. Deut. Landw. Gesell.*, 27 (1912), No. 17, pp. 243-246).—A discussion of the effect of soil, climate, feed, and other factors

on the character of the fleece of caracul lambs, based largely on results of work previously noted (E. S. R., 25, p. 175).

**Goats: Their use and management**, H. S. H. PEGLER (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 24 (1912), pp. 52-77, figs. 6).—The principal topics treated are the breeds of goats, feeding, management, and milk yields.

**The Angora and mohair industry in the Northwest** (*Portland, Oreg.* [1911], pp. 69, figs. 54).—This is a report of the proceedings of the first annual convention of the Northwest Angora Goat Association, held at Portland, Oreg., January, 1911, including several addresses on the subject of breeding, feeding, and handling goats.

[Feeding experiments with pigs], W. A. LINKLATER (*Oklahoma Sta. Rpts. 1910-11*, pp. 18-30, figs. 5).—A feeding test with 32 young pigs is summarized in the following table:

*Rations for growing pigs.*

Rations.	Average gain per head and day.	Corn required for 100 lbs. gain.
	Lbs.	Lbs.
Corn meal (full ration).....	0.38	407
Corn meal (full ration), green alfalfa (ab libitum).....	.52	294
Corn meal (half ration), green alfalfa (ab libitum).....	.38	203
Corn meal (quarter ration), green alfalfa (ab libitum).....	.22	136
Corn meal (quarter ration), green rape (ab libitum).....	.12	242
Corn meal (half ration), green rape (ab libitum).....	.26	293
Corn meal (full ration), green rape (ab libitum).....	.46	333
Corn meal (7 parts), tankage (full ration), 1 part.....	.39	347

In another test with 20 pigs lasting 160 days, on a ration of corn chop, butter-milk, and barley and sorghum forage the average daily gain was 0.51 lb., as compared with a gain of 1.22 lbs. on corn chop and buttermilk. A lot of hogs turned into a field of corn yielding at the rate of only 17 bu. per acre made a gain of 1.2 lbs. per head. Estimating the value of the grain at 7 cts. per pound, the hogs returned a value of 63.15 cts. per bushel.

A test of ear corn v. ear corn and supplementary feeds for 16 hogs averaging about 209.5 lbs. in weight gave the following results: On ear corn alone the average gain per head and day was 1.02 lbs., at a cost of 4.57 cts. per pound; on corn and tankage, a gain of 1.09 lbs. at a cost of 4.74 cts. per pound; on corn and alfalfa meal, a gain of 1.02 lbs., at a cost of 5.3 cts. per pound; and on corn and alfalfa hay, a gain of 0.96 lb., at a cost of 5.76 cts. per pound.

**Hog feeding**, W. A. LINKLATER (*Oklahoma Sta. Bul. 94*, pp. 3-16, figs. 2).—The first experiment reported in this bulletin was on the value of alfalfa forage for hogs with and without grain. Pigs averaging about 75 lbs. in weight were turned on an alfalfa field in April. At the end of 100 days the average daily gain was 0.26 lb. per head when on alfalfa alone; on alfalfa and all the dry corn chop they would eat the gain was 1.28 lbs. per head and day; on alfalfa and a half ration of corn chop the gain was 0.70 lb.

In a test of the value of cotton-seed meal as a supplementary feed, with 3 lots of 4 hogs each weighing about 100 lbs., the average daily gain per head for 77 days was as follows: On corn chop and cotton-seed meal in the proportion of 4:1, 1.05 lbs.; on the same feeds in the proportion of 6:1, 1.2 lbs.; in the proportion of 8:1, 1.18 lbs. The financial statements, however, were most favorable for the first lot.

Some advice is offered concerning the management of swine and the economical production of pork.

The brood sow and her litter, J. M. EVVARD (*Breeder's Gaz.*, 61 (1912), No. 7, p. 395, figs. 2).—Thirty-five grade and pure-bred Duroc-Jersey gilts were divided into 7 equal lots. Corn was made the basis of all rations fed. The supplements tested were meat meal, mixed grains, clover hay, molasses, and alfalfa. The results are summarized in the following table:

*Influence of the sow's feed on the offspring.*

Supplement.	Average number in litter.	Average weight of litter.		Average number of pigs saved per sow at weaning.
		Lbs.	Lbs.	
None.....	7.6	15.20	1.74	5.2
1 lb. meat meal to 30 lbs. ear corn.....	7.4	14.89	2.01	6.2
4 lbs. meat meal to 30 lbs. ear corn.....	8.8	19.62	2.23	7.0
Grain mixture.....	10.6	19.59	1.84	7.4
Cut clover and molasses.....	7.0	15.32	2.19	4.6
Clover in rack.....	6.4	14.17	2.21	5.6
Alfalfa in rack.....	7.6	17.41	2.29	6.4
Average of all.....	7.9	16.30	a 2.67	6.1

a Average weight of all pigs born.

Bacon curing on the farm, L. M. DOUGLAS (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 24 (1912), pp. 102-119, figs. 12).—This describes the bacon type of hog, the equipment for curing bacon, and methods of cutting and curing.

The stallion law and the farmer (*Kansas Sta. Circ.* 23, pp. 4).—This circular explains the reason for enacting the state stallion law, and offers suggestions to horse breeders for improving their breeding stock.

Profitable poultry raising, J. S. JEFFREY (*North Carolina Sta. Bul.* 221, pp. 89-108, figs. 7).—This discusses methods of raising and feeding chicks, and contains a brief report of a feeding experiment lasting 6 months, in which a large part of the feed consisted of grain that was not marketable. The cost of feed per dozen eggs laid during this period was 9 cts. for the Barred Plymouth Rocks and 8.45 cts. for the Rhode Island Reds. Types of poultry houses and an oat sprouter are also illustrated and described.

The utility poultry industry in Scotland, W. BROWN (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 24 (1912), pp. 236-249).—This is a statement of the present status of the poultry industry, a description of the efforts now being made to encourage poultry keeping, and a review of results which have already been secured.

Farm poultry, F. C. ELFORD (*Bul. Macdonald Col.*, 1912, pp. 59, figs. 31).—This is a popular bulletin, covering all phases of the poultry industry.

Exportation of eggs from Bulgaria (*Handels Museum*, 26. (1911), I, No. 21, p. 327; *abs. in Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and P'sunt Discases*, 2 (1911), No. 6, p. 1428).—Statistical data on exports of eggs from Bulgaria for a number of years are given. Most of the eggs at the present time are sent to Germany, whereas formerly they were exported to Austria.

Oregon Station trap nest, J. DRYDEN (*Oregon Sta. Circ.* 19, pp. 4, figs. 2).—A description of this trap nest has been previously noted (*E. S. R.*, 21, p. 75).

The retail butcher, R. S. MATTHEWS (*Memphis, Tenn.* [1911], pp. 101, pl. 1, figs. 4).—This contains advice on slaughtering animals, and also recipes for curing ham and bacon, drying beef, and making sausage and head cheese. Prices at which meat must be sold in order that the butcher may make a profit are presented in tabular form.

## DAIRY FARMING—DAIRYING.

**Influence of fatness of cow on percentage of fat in milk, C. H. ECKLES** (*Missouri Sta. Bul. 100, pp. 183-202, figs. 12*).—This contains records of the station herd in addition to those previously noted (E. S. R., 23, p. 179), which show that on a restricted ration the percentage of milk fat may be abnormally increased for some time after calving if the cow is in a fat condition, and that the percentage of milk fat gradually increases with the advance in lactation for the cows moderate to thin in flesh.

Data are also taken from the advanced register of the Holstein-Friesian Cattle Association, and submitted as further proof that the percentage of fat may be abnormally high when the cow is in a fat condition at calving. One cow was entered in the advanced register with an official test of 4.09 per cent fat, although her average for the year was 2.76 per cent. Similar results are recorded for Ayrshires and Jerseys.

The following conclusions are drawn: "The percentage of fat in milk can be influenced to a marked extent for the first 20 to 30 days by the fatness of the animal at parturition. This influence appears to extend in some cases in a less degree for at least 3 months. Underfeeding of the animal after parturition seems to be a necessary condition to bring about this abnormal percentage of fat in the milk.

Tests of dairy cows made for short intervals in the beginning of the lactation period can not be depended upon to indicate the normal percentage of fat produced by the cows tested."

**Age as a factor in milk production, F. L. KENT** (*Oreg. Countryman, 4 (1912), No. 9, pp. 18-20*).—Data are presented showing that the average yield of 5 cows at the Oregon Station and 10 cows at the Missouri Station was heaviest during the fourth lactation period.

**Feeding experiments with dairy cows, C. I. BRAY** (*Oklahoma Sta. Rpts. 1910-11, pp. 30-36*).—On a ration of wheat bran, corn chop, alfalfa hay, and silage the cost of milk per gallon was 11.2 cts. When on a ration similar to the above, with the addition of cotton-seed meal, the cost of milk was 10.9 cts. per gallon, but the quantity was slightly decreased. In another test of the cost of milk production on a ration of bran, corn chop, cotton-seed meal, and alfalfa hay the cost was 11.7 cts. per gallon. On a similar ration, with silage as a supplement, the cost was 10.4 cts. per gallon and the yield was slightly increased.

**Investigations on the effect of palm-nut cake on milk production, O. KELLNER ET AL.** (*Ber. Landw. Reichsanstalt Juncrn, 1911, No. 24, pp. XIII+843*).—This is the special report containing the complete details of the work previously noted (E. S. R., 26, p. 169).

**The dairy farm from the view point of soil fertility, M. KAWASHIMA** (*Oreg. Countryman, 4 (1912), No. 9, pp. 31-35*).—Data are presented to illustrate the differences in amount of fertilizing elements removed from the dairy farm when the product is sold as whole milk, cream, cheese, or butter.

**The bacterial content of the normal udder, F. C. HARRISON and A. SAVAGE** (*Rev. Gén. Lait, 9 (1912), No. 6, pp. 121-131*).—These experiments were undertaken to ascertain the species of bacteria which normally occur in the bovine udder, their mode of entrance, and their action and hygienic importance.

Bacteria were isolated from the foremilk, middle milk, and strippings of heifers and mature cows. The bacterial content appeared to be small, and aside from the foremilk appeared to be practically limited to a few species of white and yellow cocci. *Micrococcus albidus* and *M. varians* were predominant in both virgin and mature udders.

The following conclusions are drawn: "Aside from the teat and cistern the flora of the normal udder is a small one and consists of a few species of cocci. The flora of the teat and cistern is subject to change which may be either practically continuous or slow. All organisms found in the lower part of the udder are unable to penetrate the upper and secreting regions. The flora of the fore-milk is not necessarily any indication as to what germs are located within the gland. All bacteria with which the teat openings come in daily contact are unable to effect an entrance. The lactic-acid bacillus is occasionally present in normal udders. The cocci that characterize the middle milk and strippings come from an internal source."

**Bacteria in milk**, L. A. ROGERS (*U. S. Dept. Agr., Farmers' Bul. 490, pp. 23, figs. 5*).—A revision of Farmers' Bulletin 348, previously noted (*E. S. R., 20, p. 977*).

The bacterium of contagious abortion of cattle demonstrated to occur in milk, A. D. MELVIN (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 198, pp. 3*).—The undescribed pathogenic bacterium found in milk, referred to in an article previously noted (*E. S. R., 26, p. 87*), has been found by means of the complement fixation test to be identical with the organism causing contagious abortion in cattle. Although not yet known to produce ill effects in man, the discovery furnishes an additional reason for pasteurizing milk. See also a note by Smith and Fabyan (*E. S. R., 26, p. 586*).

Experiments on the demarcation of *Streptococcus acidilactici* from *S. pyogenes* and *S. lanceolatus*, Y. SAITO (*Arch. Hyg., 75 (1912), No. 3, pp. 121-133*).—Cocci grown on different media indicated that *S. acidilactici* is so closely related to *S. lanceolatus* that it might be considered as the nonvirulent type of that species. On the other hand, there are a number of characters which distinguish it from *S. pyogenes*.

A bacteriological study of the milk supply of Washington, D. C., J. J. KINYOUN and L. V. DIETER (*Amer. Jour. Pub. Health, 2 (1912), No. 4, pp. 262-274, figs. 2*).—Thirty-five per cent of the raw milk and cream samples examined had a bacterial content under 500,000 per cubic centimeter, 20 per cent between 500,000 and 1,000,000, and 45 per cent over 1,000,000.

It is stated that the colon and streptococci content of milk can be taken with reasonable certainty as a measure of the dirt content and that the chief cause of the poor quality of milk lies in the careless handling of the milk before it leaves its place of origin. Although milk examined in October and November, 1910, showed a great number of bacteria, the colon bacilli and streptococci being present in large numbers in over 40 per cent of the samples, yet the average daily temperature was not high. Many of the samples of "commercially pasteurized" milk contained large numbers of bacteria.

"It is impossible to reconcile the fact that a so-called pasteurized milk containing as many as 38,000,000 bacteria per cubic centimeter, and 210,000 of these colon bacilli and 100,000 streptococci, is anything more than a dirty, bad milk."

Report of the commission on milk standards appointed by the New York milk committee (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 27 (1912), No. 19, pp. 673-691*).—This contains data on chemical and bacteriological standards for milk and cream, methods of reporting bacteria and dirt content, municipal ordinances relating to the sale of milk and cream, and other matters pertaining to the improvement and regulation of the city milk supply.

**Directions for the home pasteurization of milk**, L. A. ROGERS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 197, pp. 3, fig. 1*).—A revision of Circular 152, previously noted (*E. S. R., 22, p. 179*).

The resorption of lime in the animal body by the employment of pasteurized and sterilized milk, J. ZIMMER (*Ueber Kalkresorption im Tierkörper bei Verwendung von pasteurisierter und sterilisierter Milch. Inaug. Diss., Univ. Strassburg, 1911, pp. 12*).—In experiments with dogs, pasteurizing or sterilizing milk did not affect the percentage of calcium resorbed.

[Regulations concerning the use of preservatives in milk and cream], T. REECE (*Hourd's Dairyman, 43 (1912), No. 16, pp. 631, 632*).—This gives the regulations drafted by the British Local Government Board which will be enforced after June 1, 1912, and which prohibit the use of preservatives in milk and cream.

The sterilization of milk bottles with calcium hypochlorite, H. A. WHITTAKER and B. M. MÖHLER (*Amer. Jour. Pub. Health, 2 (1912), No. 4, pp. 282-287*).—The bacterial count of bottles before treatment showed a wide range in the number of organisms. Counts on the total number of bottles examined from 8 sources showed a minimum count of 30, a maximum count of 1,600,000, and an average count of 120,000 per bottle. The counts on these same bottles after treatment with calcium hypochlorite showed a minimum count of 0, a maximum of 540, and an average of 45 per bottle. During the investigation the amount of hypochlorite required to produce efficient results was reduced from 20 to 10 parts of available chlorine per million, and the time of exposure from 1 hour to 20 minutes.

"The sterilizing of milk bottles by submerging in a solution of calcium hypochlorite appears to be a quick and inexpensive method of materially reducing the organisms present. It is not the intention of the writers to recommend this as a substitute for thorough steam sterilization but simply to be used as an expedient when the other method is impracticable."

Effects of alkali water on dairy products, C. LARSEN, W. WHITE, and D. E. BAILEY (*South Dakota Sta. Bul. 132, pp. 229-254*).—This experiment was undertaken to obtain data on the effect of water containing a large amount of mineral substances on milk and milk products.

Analyses are given of the mineral constituents in the water from 14 different wells. The water used in these experiments had a distinct saline, acid, and sharp taste, but as far as could be determined it did not have any undesirable flavors due to decayed organic matter. It contained the highest percentage of total minerals, and also the greatest quantity of sulphates of any of the waters tested.

Although the experimental cows received 0.5 lb. more soluble minerals per day than the control animals, the percentage of total ash in the milk was not affected. The ash varied in composition, the sulphates and potash being the 2 chief ash constituents which showed an increase upon feeding alkali water, but this was not sufficient to affect the normal properties of the milk and milk products.

It is concluded that alkali water free from decayed organic matter and foreign odors does not taint the milk or butter. It is thought that the complaints made by some dairy farmers concerning the undesirable effect of alkali water on the flavor and properties of milk must be accounted for in some other way, probably by the decayed organic matter which is common in alkali water, as such water dissolves more organic matter than ordinary well water. This is especially true if the water contains much sodium carbonate, or what is commonly called "black alkali."

The coagulability of milk with rennet was not affected by the alkali water, but coagulability was found to bear a relation to the percentage of calcium in the milk and the individuality of the cow. The milk low in calcium required the

most rennet for curdling and produced the softest coagulum, and this milk was produced by cows well advanced in the gestation period.

The quality of salted butter washed in alkali water was unimpaired, but unsalted butter washed in alkali water was scored about 1 point lower in quality than butter washed in normal wash water. Although the alkali wash water contained a large number of nonacid types of bacteria, they were almost entirely supplanted by a large number of acid forms in the butter shortly after its manufacture. Acid tests confirmed the results of the judges who scored the butter that alkali water free from organic matter does not affect the quality of butter. Although there were more organisms in alkali water than in the soft water they decreased rapidly as the butter aged, and were no more deleterious to the quality of the butter than those found in ordinary well water.

Chemical analyses of cheese when 1 month old showed no differences from that made with ordinary soft water. Brine-soluble protein was low and insoluble protein high in freshly made cheese from milk produced by the cows receiving alkali water, but this difference diminished after the cheese had been cured 1 month.

The "coming of age" of the Babcock test, H. L. RUSSELL (*Wisconsin Sta. Circ. Inform.* 32, pp. 3-18, figs. 7).—A brief historical sketch of dairying in the United States since 1851, with special reference to the influence of the discovery of the Babcock test in putting the industry upon a more scientific basis.

On the composition of butter fat in butter of Danish and Russian Siberian origin, G. JÖRGENSEN (*Tidsskr. Landökonomi*, 1911, No. 9, pp. 603-614).—A summary of results of the examination of 11,690 samples of Danish butter and 2,374 samples of Siberian butter, made at Copenhagen from 1896 to 1910.

The index of refraction at 40° C. for the Danish butters ranged from 1.4525 to 1.4569, with an average of 1.4545. For the Siberian butter the range was 1.452 to 1.4574, and the average 1.4545. The amount of normal alkali required to neutralize 100 gm. of volatile fatty acid ranged from 47 to 71.9 cc., with an average of 59, in the Danish butter, and from 41 to 69.9 cc., with an average of 54 in Siberian butter. A high refraction number was invariably accompanied by a low figure for volatile acids and vice versa.

Department of dairy husbandry, R. C. POTTS (*Oklahoma Sta. Rpts.* 1910-11, pp. 36-44).—A financial statement of the operations of the college creamery for the fiscal year ended June 30, 1910, is reported. The number of patrons was 466, the average percentage of cream 35, average price paid per pound for milk fat 25.16 cts., pounds of butter made 242,466, percentage of overrun 18.64, average price received per pound for butter 26.928 cts., average cost of manufacturing a pound of butter 4.255 cts.

For the year ended June 30, 1911, the figures were as follows: Number of patrons 405, percentage of cream 33, price paid for milk fat 23.603 cts., pounds of butter made 160,105, percentage of overrun 16.7, average price received per pound for butter 24.5 cts., cost of manufacturing 1 lb. of butter 5.08 cts.

The dairy conditions on 100 farms were investigated, and total cash returns of 33 are presented in tabular form. In 7 of the herds the average net loss from 87 cows was \$2.58 per cow per year, while in 8 herds the average net profit from 72 cows was \$21.32 per cow.

Better butter for Kansas (*Kansas Sta. Circ.* 24, pp. 4, figs. 8).—This contains suggestions for keeping dirt and bacteria out of milk and cream.

Experiments with pure cultures for making Parmesan cheese, C. BESANA (*Bul. Agr. [Milan]*, 46 (1912), No. 7, p. 1; *Molk. Ztg. [Hildesheim]*, 26 (1912), No. 31, pp. 555, 556).—A report of a successful attempt in using pure cultures

for Parmesan cheese. Favorable results were obtained by placing the cheese mass in a specially constructed oven, and holding it there in a moist atmosphere at a temperature of from 40 to 45° C. for from 12 to 24 hours.

**Studies on the bacterial flora of cheese**, C. GORINI (*Ztschr. Gärungsphysiol.*, 1 (1912), No. 1, pp. 49-59, fig. 1).—This has been previously noted from another source (E. S. R., 25, p. 582).

**Factory arrangement**, F. BALLANTYNE ET AL. (*N. Y. Produce Rev. and Amer. Cream.*, 33 (1912), No. 26, pp. 1106-1108, fig. 1).—This contains a number of plans for arranging machinery and cooling facilities in creameries.

## VETERINARY MEDICINE.

**A text-book of ophthalmology for veterinarians**, H. MÖLLER (*Lehrbuch der Augenheilkunde für Tierärzte*. Stuttgart, 1910, 4. rev. and enl. ed., pp. VIII+468, pls. 2, figs. 89).—This is a fourth revised and enlarged edition.

**Diagnostic methods**, R. W. WEBSTER (*Philadelphia*, 1912, 2. ed., rev. and enl., pp. XXXV+682, pls. 37, figs. 164).—This is the second edition of this well-known work, which deals with chemical, bacteriological, and microscopical methods. The new material includes the antiformin method for tubercle bacilli; the Much method for staining tubercle bacilli; the Neubauer and Fischer test for gastric carcinoma; the Gross method for trypsin; Folin's newer methods for urinary sulphur compounds; the formalin method for ammonia in urine; Benedict's and Bang's tests for glucose in urine; the phenolsulphone-phthalein test for functional activity of the kidneys; the Wright and Kinnicutt method of counting the blood plates; sulphhemoglobinemia; and the tuberculin and luetin reactions. The sections dealing with bacteriology of the blood and with serum pathology have been greatly enlarged.

**A study of Ascoli's reaction (thermoprecipitin) for the diagnosis of anthrax**, P. SILVA (*Rev. Gén. Méd. Vét.*, 19 (1912), No. 225, pp. 503-505).—This reaction can be employed for detecting sausage and other meat products prepared from animals affected with anthrax.

**The use of Ascoli's diagnostic method in practice**, K. PRESSLER (*Berlin. Tierärztl. Wechschr.*, 28 (1912), No. 11, pp. 192, 193).—This is a report on an authentic case of anthrax in which Ascoli's method gave negative results, due to the low titer of the serum employed. The author considers the method a good one, but points out that the serum employed should always be tested with filtered (bisque) blood obtained from animals having anthrax. Other improvements are also suggested.

**Dourine, its pathogenicity, and a practical test of the efficacy of drug treatment, with especial reference to the action of atoxyl and arsenophenylglycin**, A. WATSON (*Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 39-45).—This is a reprint from the report previously noted (E. S. R., 26, p. 881).

**Is foot-and-mouth disease disseminated by milk-collecting stations?** (*Molk. Ztg. [Hildesheim]*, 25 (1911), No. 52, pp. 981, 982).—It is not believed that milk-collecting stations have any great part in the dissemination of the virus.

**Recent methods for the diagnosis of glanders**, F. B. HADLEY (*Amer. Vet. Rev.*, 41 (1912), No. 2, pp. 152-157).—For ordinary clinical use the agglutination test was found to be the most desirable, particularly for cases of recent infection. In this work the greatest number of horses examined gave a reaction with the 1:200 dilution, others with the 1:500 dilution, and only two with the 1:800 dilution. It is pointed out that variations in the agglutinating power of the blood may occur within narrow limits in the healthy horse, but if these variations are very marked the animal must be considered with suspicion. All the

horses tested which gave a reaction in the 1:1,000 dilution were proved to be glandered by other tests. Animals reacting in such high dilution are diseased and should be immediately quarantined or destroyed. Satisfactory results could not be obtained with the Konew method (E. S. R., 24, p. 184).

**Glanders and combating glanders in Kurland.** L. GERONIMUS (*Arch. Vet. Nauk [St. Petersb.], 41 (1911), No. 12, pp. 1542-1565; abs. in Ztschr. Immunitätsf. u. Expt. Ther., 11, Ref. 5 (1912), No. 5, p. 1003*).—In 1910 the government of Kurland had 172 cases of glanders at 49 locations. Of these animals 168 were killed and 4 died. Comparative tests made for the purpose of determining the value of anaphylaxis tests show that the subcutaneous mallein test and the conjunctival test gave approximately parallel results.

In regard to the phagocytic action of various sera upon some of the bacteria occurring in hemorrhagic septicemia, R. BROLL and ST. ANGELOFF (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 4 (1908), No. 5-6, pp. 469-475; abs. in Berlin. Tierärztl. Wchnschr., 27 (1911), No. 34, p. 612*).—The opsonic power of various sera was tested against swine plague, fowl cholera, game and bovine plague, and septic calf pneumonia bacteria.

It was noted as a result of the tests that the polyvalent swine plague serum possesses an opsonic power but not a bacteriolytic or bactericidal power. The swine plague bacterium (*Bacterium suiscepticus*) is also influenced opsonically to a slight degree by normal horse, bovine, and hog sera. The polyvalent swine plague serum, on the other hand, has a strong opsonic power which is still present in a dilution of 1:50. In addition to the *B. suiscepticus*, the fowl cholera bacterium was affected by the swine plague serum, although to a lesser extent. The opsonic action of the polyvalent serum upon the game and bovine plague bacterium was found to be very weak, whereas the calf pneumonia serum behaved as would a normal serum.

It was further noted that the opsonins were heat labile. Heating the polyvalent serum for  $\frac{1}{2}$  hour at 60° C. (inactivated) was sufficient to cause a considerable reduction in the opsonic power.

**An extensive epizootic of rabies,** A. CARINI (*Ann. Inst. Pasteur, 25 (1911), No. 11, pp. 843-846; abs. in Jour. Amer. Med. Assoc., 58 (1912), No. 2, p. 149*).—The author reports an extensive epizootic of rabies in cattle and horses in Brazil, which caused the death of some 4,000 cattle and 1,000 horses.

"There was no unusual prevalence of rabies in dogs at the time, but it was noticed that bats in broad daylight attacked and bit the cattle, and the author suggests that bats may have been the source of the extensive epizootic. It has been prevailing for several years but exclusively in a narrow strip of the country. As its true nature was not discovered until recently, prophylaxis has not been on the correct basis. The animals affected all die after a few days, and the meat and hides have been utilized but no mishaps have been known to follow."

**Studies in regard to tuberculosis,** A. FONTES (*Mem. Inst. Oswaldo Cruz, 3 (1911), No. 2, pp. 196-217, pls. 7*).—Thinking that some of the results obtained in previous work (E. S. R., 25, p. 184) might be due to the presence of enzymes such as zymase, protease, and oxidase, the author made tests with filtrates which contained the granula obtained from the cultures of tubercle bacilli.

Although negative results were obtained in the enzym tests, a substance capable of dissolving or saponifying fats was noted in the juice obtained from caseated and ruptured lymphatic glands. The granular forms of the tubercle bacillus were produced by injecting extracts from the diseased lymphatic glands and the human type of bacillus into the abdominal cavity of guinea pigs. Granula were noted in the lymphatic glands of the experimental animals,

but in no instance was the regular acid-fast tubercle bacillus detected. Most of the experimental animals had a generalized tuberculosis. The extracts of caseified foci contained a specific substance which was antagonistic to the tubercle bacillus, and which according to the author does not originate from the bacillus. The use of iodine preparations in tuberculosis increased the process of congestion.

**Tuberculosis** (*Illinois Sta. Circ.* 158, pp. 3-21, figs. 13).—This is a republication of the compilation previously noted (E. S. R., 26, p. 378).

In regard to the chemical composition of the tubercle bacillus, T. PANZER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 78 (1912), No. 5, pp. 414-419).—The author points out that the published analyses of the tubercle bacillus do not give any clue in regard to the principal constituents of this organism.

Tubercle bacilli which were cultivated on glycerin bouillon were killed by heat, collected on a filter, washed with water, and dried in a vacuum over calcium chlorid. The weight of dried bacilli obtained was 2.7 gm. They were then rubbed up and extracted successively with ether, alcohol, cold water, 1/20-normal hydrochloric acid, 1/20-normal sodium carbonate, 1/20-normal sodium hydrate, hot water, and 2 per cent potassium hydrate.

The cold water, hydrochloric acid, sodium carbonate, sodium hydrate, and potassium hydrate extracted very little material. The unsaponifiable material contained in the ether extract of the bacilli, precipitated with digitonin and extracted with petroleum ether and xylol, yielded a mixture of colorless crystals and a yellow, smeary mass which did not give the cholesterol reaction. According to the author two higher alcohols are probably present. The alcoholic solution obtained reduced Fehling's solution and on evaporation yielded a brown, partly crystalline residue.

The hot water extract of the bacilli on evaporation left a residue which reminded one of gum arabic. This substance was free from sulphur, nitrogen, and phosphorus, gave Molisch's reaction with  $\alpha$ -naphthol, was precipitated from the aqueous solution with alcohol or lead acetate, and after boiling for a time with hydrochloric acid reduced Fehling's solution. On oxidizing with nitric acid no mucic acid was produced, the chief product being oxalic acid. In addition a crystalline substance resembling calcium saccharate was also obtained. This substance is probably pectin.

The residue remaining after extraction of the above reagents and containing nitrogen gave Molisch's reaction, and after boiling with hydrochloric acid reduced Fehling's solution. The filtrate obtained from treating another portion of the residue with pepsin did not give a biuret reaction, although the solid particles remaining did. This resistant body is evidently chitin.

**Tuberculosis of the abomasus of bovines**, P. CHAUSSÉ (*Bul. Soc. Cent. Méd. Vét.*, 88 (1911), No. 20, pp. 452-476, figs. 12).—A discussion in regard to the macroscopical and microscopical findings and the pathology of this condition. The article contains profuse illustrations of pathological preparations.

**The ophthalmic test for bovine tuberculosis**, A. WILSON (*Jour. Compar. Path. and Ther.*, 24 (1911), Nos. 1, pp. 59-66; 2, pp. 116-126).—This is a critical study of the ophthalmic and subcutaneous tests for detecting tuberculosis. Considerable stress is laid upon the unreliability of diagnosing tuberculosis on the basis of the simple ophthalmic test alone. Satisfactory results can only be obtained when both tests are conducted together.

**Utilizing the work of our international commission on the control of bovine tuberculosis**, M. H. REYNOLDS (*Amer. Vet. Rev.*, 41 (1912), No. 2, pp. 196-200).—In this paper the author points out the services rendered by agricultural colleges, farmers' institutes, state live-stock sanitary boards, etc., in combating tuberculosis.

In regard to the type of tubercle bacilli which is present in tuberculosis of swine, H. E. KERSTEN and E. UNGERMANN (*Tuberkulose Arb. K. Gesundheitsamt., 1912, No. 11, pp. 171-199*).—From 19 tuberculous swine pure cultures of the bovine type of bacillus were obtained and tested as regards virulence with guinea pigs. Seventeen of the cases were taken at random in the slaughter-houses while the 2 remaining ones were suspected of being of human origin. One of the latter cases on autopsy seemed to have its inception as a result of castration.

Infectious abortion in bovines, MIESSNER (*Berlin, Tierärztl. Wehnschr., 28 (1912), No. 18, pp. 316, 317*).—After investigating the value of the sero-diagnostic methods with cattle in the eastern provinces of Germany, the author finds that the agglutination and complement fixation methods, in the form in which they have been used for diagnosing glanders, are a reliable means for diagnosing infectious abortion in bovines. In practically all cases the serum test substantiated the clinical findings. Infectious abortion was found to have no relation to vaginal catarrh. The author will publish a more detailed report of this work later.

A comparative investigation in regard to milk from cows having infections of the udder, E. SEEL (*Ztschr. Untersuch. Nahr. u. Genussmit., 21 (1911), No. 3, pp. 129-168; abs. in Ztschr. Angew. Chem., 24 (1911), No. 12, p. 561*).—From the results it could be noted that the reaction of the secretion from animals suffering from mastitis is alkaline toward litmus. The milk sugar, fat, and chlorids are much diminished, while the protein, particularly albumin, is increased. The refraction of fats showed considerable variation from the normal.

Abnormal milk from cows affected with an inflammation of the mammary glands, C. AMBERGER (*Ztschr. Untersuch. Nahr. u. Genussmit., 23 (1912), No. 8, pp. 369-379*).—A description of the chemical changes taking place in the milk from 2 animals during the cycle of the disease. The most pronounced changes were the same as those noted in the abstract above with the exception that the chlorin content was increased. One of the samples showed at the outset an increased fat content.

Investigation of milk from cows suffering from mastitis for its enzym content, H. ULMANN (*Untersuchungen von Milch euterkrankter Kühe auf ihren Enzymgehalt. Inaug. Diss., Tierärztl. Hochsch. Stuttgart, 1912, pp. 78; rev. in Deut. Schlacht u. Viehhof Ztg., 12 (1912), No. 21, pp. 319, 320*).—The enzym content of milk was found to be influenced by the presence of mastitis, which in most instances had a tendency to increase it. It, however, undergoes marked fluctuations and is greatly dependent upon the nature of the changes which have taken place in the secretion. The catalase content is almost always increased in both the mixed milk and the milk obtained from the inflamed quarter. Such milk is usually alkaline. The reductase reaction (Schardinger's enzym) in the first stages of mastitis is present in either a normal or an increased amount, so it is, therefore, without value for detecting mastitic animals. Oxidase, peroxidase, and diastase tests are also of no value for this purpose.

Contagious vaginitis in cows, P. STAZZI (*Vet. Jour., 68 (1912), No. 440, pp. 83-88*).—The following measures are recommended by the author, who was commissioned by the Italian minister of the interior to investigate and report on this disease, which is of great importance in Italy as well as elsewhere.

“Provide open pasturage for all cows, especially for those whose conception is tardy. Wash frequently the flanks, tails, and feet of cattle with soap and soda. Cleanse and disinfect weekly with boiling soapsuds or lime wash all stalls, harness, etc. Disinfect the genital organs of bulls before and after

coitus (2 per cent solution of lysoform recommended). Treat heifers till cured according to veterinary advice, suspending the treatment during œstrum. Douche with 2 per cent solution of carbonate of soda during œstrum, especially immediately before covering. After the seventh month of pregnancy use only the mildest of medicaments, such as ointments containing a very little belladonna and only 0.5 per cent of a nonirritant antiseptic, lysoform, etc. Isolate or slaughter cows suffering from chronic metritis and those in whom œstrum has entirely ceased. After parturition inject weak solutions of iodine—a teaspoonful in each quart of tepid water."

The treatment of contagious vaginitis in cattle, E. WALTER and A. GÄRTNER (*Berlin. Tierärztl. Wchschr.*, 28 (1912), No. 8, pp. 133-140; *abs. in Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 74-82).—In attempting to discover a disinfectant which might be kept in constant contact with the mucous membrane and one which is at the same time simple of application, the authors have made successful use of a eucerin salve. In preparing this ointment the anhydric eucerin is gradually worked up in a mortar with the desired quantity of a watery solution of the medicament until the mixture is quite uniform. The complete absorption of the water is indicated by the clinging of the mixture to the sides of the mortar.

In the experiments here reported eucerin ointments containing 10 per cent bacillol, 0.5 per cent sublamin, and 25 per cent water; 10 per cent sapoformol, 0.5 per cent sublamin, and 25 per cent water; 8 per cent bacillol, 0.6 per cent sublamin, and 25 per cent water; 3.5 per cent copper sulphate and 25 per cent water; 10 per cent copper sulphate and 25 per cent water; 10 per cent copper citrate and 25 per cent water; 8 per cent bacillol, 0.6 per cent sublamin, and 25 per cent water; 8 per cent bacillol, 0.5 per cent sublamin, and 25 per cent water; and 8 per cent bacillol and 25 per cent water, respectively, were employed.

From the results obtained it may be concluded that animals affected with vaginitis can be cured in this way. "The results are the same whether the cases are recent or of long standing, and also if other methods of treatment have been tried. This result is obtained by the application of a disinfectant which is present in the same proportion in a number of other materials that are in common use for the treatment of this disease. Since these preparations are by no means so successful, the authors concluded that the difference must lie in the vehicle in which the disinfectant was suspended. . . .

"It is absolutely necessary that the eucerin mixture be applied to the whole of the diseased membrane. . . . Relapses ceased to occur when the salve was distributed throughout the vagina by means of a special instrument—cannifriator. The even and thorough distribution of the salve over the mucous membrane by means of this instrument was controlled by the examination of 3 animals that were slaughtered. Ten gm. of the mixture were smeared over the walls of the vagina by its means shortly before death, and after slaughter it was found that the entire mucous membrane was covered with a layer about 1 mm. thick. In practically all the experimental animals application of the bacillol mixture caused the disappearance of the nodules within 4 to 5 days, and it was only in quite exceptional cases that traces of the lesions were visible on the fifth day. In cases where the treatment was continued for longer periods it was done with the idea of preventing relapses with greater certainty and not to improve the local curative effect. The treatment was quite simple and was not followed by any untoward symptoms, such as restlessness and straining. The nature of the treatment with the soft, semifluid salve is such that animals in the last stages of pregnancy may be submitted to it without hesitation. . . .

"Since no immunity is conferred by this method of treatment steps must be taken, by resorting to disinfection, to prevent the persistence of the cause of the disease on the bodies of the animals and in the stalls. For this reason 2 disinfections were practiced in the later experiments; the hindquarters of the perineal regions of the animals were washed with either 5 per cent bacillol or 5 per cent sapoformol, and the stalls were subjected to a thorough cleansing, followed by a disinfection with lime wash. In order to prevent the introduction of fresh infection through the agency of the bull, this animal was also subjected to treatment. About 10 gm. of eucerin mixture were introduced into the sheath and distributed by massage. As in the case of cows this treatment was carried out on 10 occasions, 5 on consecutive days and 5 on every second day."

**Nodular intestinal disease of cattle**, W. JOWETT (*Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 15-22, figs. 5).—The author thinks the species *Oesophagostomum hiramosum* the cause of the nodular disease of cattle in the Cape Peninsula, South Africa. See also a previous note (E. S. R., 26, p. 382).

**A contribution to the illustration of the injury caused by the ox warble and the manner of combating it**, H. J. DE VRIES (*Ein Beitrag zur Illustration des durch die Dasselfliege verursachten Schadens, und die Bekämpfung derselben beim Rindvieh. Inaug. Diss., Univ. Bern, 1910, pp. 63, pls. 5*). In the first part of this work the author briefly reviews the history of the biological study of the ox warble (*Hypoderma bovis*). Observations of the larva in the esophagus, vertebral canal, and subcutis are then reported. Discussions of the effect of the wandering of the larva upon the tissues, the amount of injury caused as based upon the decrease in milk, flesh, and value of the hide, and methods of combating it, especially as applied to the Netherlands, follow.

Several plates are included which illustrate the life history of the insect in its various stages, injury caused to the hide, etc.

**A campaign against the ox warble**, V. DROUIN (*Rec. Gén. Méd. Vét.*, 19 (1912), No. 226, pp. 557-571, pls. 2, figs. 3).—A summarized account of the ox warble, its economic importance, biology, prophylaxis, etc.

**Bacillus enteritidis Gärtner in the carcasses of eight calves**, H. WINZER (*Ztschr. Fleisch u. Milchhyg.*, 22 (1911), No. 3, pp. 81-84; abs. in *Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 57-59).—"The author's experience in connection with the occurrence of organisms of this group in meat is at variance with the scanty published references, in that within 4 months he has been able to isolate from the carcasses of 8 calves organisms which on morphological, cultural, and serological grounds undoubtedly belong to the Gärtner group."

**Melanosis in calves**, A. JAEGER (*Berlin. Tierärztl. Wchnschr.*, 27 (1911), No. 44, pp. 793-798).—A contribution in regard to the relation of melanosis to cancer.

**On the treatment of contagious pneumonia (Brustseuche) of the horse with Salvarsan**, NEVERMANN (*Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 7, pp. 119-125; abs. in *Jour. Compar. Path. and Ther.*, 25 (1912), No. 1, pp. 63, 64).—"Sixty-five stallions were treated with Salvarsan, and of these 55 were free from fever within 5 days, at the longest, after a single injection of 3 gm. The other 10 animals received a second dose of 2 gm. on the fifth day of the disease, and the temperature of these was normal on the eighth day from the onset of symptoms. No untoward symptoms followed the injection of Salvarsan, and it was very striking how quickly the animals treated with the drug recovered."

**Agglutination reactions during the process of hog cholera serum production**, W. GLTNER (*Centbl. Bakt. [etc.]*, 1. Abl., Orig., 60 (1911), No. 6, pp.

552-579; *abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 5 (1911), No. 4, pp. 961, 962*).—Previously noted from another source (E. S. R., 26, p. 785).

In regard to immunizing against hog cholera and swine plague, H. PRINZ (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 11 (1912), No. 2, pp. 125-152; abs. in Berlin. Tierärztl. Wchnschr., 28 (1912), No. 17, p. 299*).—After making an examination of a number of cases of swine plague in young pigs the author concludes that the work of Löffler and Schütz does not determine the etiology of this disease. For combating it, he recommends extreme hygienic measures, protective vaccination occupying only a secondary place.

The etiology of hog cholera seems to have been worked out. In this disease protective vaccination is of great importance. The protective and curative action is the best when a composite serum is employed.

Combating swine plague by vaccinating pregnant hogs, F. TRAIN (*Berlin. Tierärztl. Wchnschr., 28 (1912), No. 3, pp. 45, 46*).—By vaccinating 17 pregnant hogs in infected stalls with polyvalent swine plague bacilliary extracts, pigs were obtained free from the disease and went on so to maturity. Antiseptin was used for 23 other animals. Of these 22 gave birth to sound litters and 3 others yielded pigs with exanthema, but without a cough. Three additional animals which received antiseptin and antiserum simultaneously yielded sound offspring.

The results obtained by other workers with these preparations are included.

On the chemistry and toxicology of ascarids, F. FLURY (*Arch. Expt. Path. u. Pharmakol., 67 (1912), No. 4-5, pp. 275-392*).—The first part of this work (pp. 275-338) deals with the chemistry, the second part (pp. 339-392), with the toxicology of ascarids.

## RURAL ENGINEERING.

Fundamental principles in tile drainage, J. L. PARSONS (*Proc. Iowa Engin. Soc., 23 (1911), pp. 39-38*).—This is a paper read before the Iowa Engineering Society, held at Des Moines, February 15-17, 1911.

The essential features in planning a tile drainage system are pointed out and discussed, among them the planning of grade lines, determining the sizes of tile, and laying out and spacing laterals.

The reclamation of Missouri lowlands for agricultural purposes, F. F. SHAFER (*Colman's Rural World, 65 (1912), Nos. 17, p. 1; 18, p. 1; 19, p. 1*).—The author briefly discusses some of the principal factors that should guide an engineer in making plans for drainage improvement districts, among which are climate, rainfall, topography, watershed, vegetation, and soil characteristics, and describes tile drainage and its benefits.

Results of experiments made to determine the waste of water by cultivators in irrigating their fields during the 3 years 1907-10, W. B. GORDON (*Punjab Irrig. Branch Papers, No. 11, pt. 2 B, pp. 5*).—The results of these experiments show that the average cultivator in the Punjab in applying the water to his fields wastes on an average at least 20 per cent of it. Dividing the fields into compartments and insisting upon the water being delivered separately into each compartment are advocated.

[Problems relative to irrigation of fields], J. M. PUJADOR (*Rev. Inst. Agr. Catalán San Isidro, 61 (1912), No. 7, pp. 99-102, figs. 3*).—Systems of field irrigation are described, consisting essentially of motor-driven pressure pumps, pipe or hose systems for conveying the water, and apparatus for sprinkling and distributing the water over the fields.

A kerosene motor for irrigation, R. OLNEY (*Irrig. Age, 27 (1912), No. 6, p. 218, figs. 2*).—Attention is called to the use of kerosene motors for driving

irrigation pumps and a table of test results is given showing the total cost of fuel per brake horsepower, for a season of 80 days, of steam and gasoline as compared to kerosene. Data derived from the operation of 3 types of steam engine, 1 type of gasoline engine, and 1 type of kerosene engine, ranging from 30 to 100 horsepower, show that the cost of fuel for the kerosene engines was approximately one-half that for the gasoline engines, and approximately two-thirds that for the steam engines.

**Irrigation laws of the State of Nebraska in force July 7, 1911, D. D. PRICE** (*Lincoln, Nebr.: Bd. Irrig., Highways, and Drainage, 1911, pp. 72*).—A compilation.

**Triennial revenue report of the public works department, irrigation branch, Bengal, for the 3 years ending 1910-11, T. BUTLER** (*Trien. Rev. Rpt. Pub. Works Dept., Irrig. Branch, Bengal, 1910-11, pp. 111+104, pls. 16*).—This report gives tabulated statements showing the areas irrigated, the capital outlay, and financial results of the canals in Bengal, diagrams illustrating the same, and tables of rainfall data, water duty data, crop experiments, and values.

**Fifteenth biennial report of the state engineer of Colorado, C. W. COMSTOCK** (*Bienn. Rpt. State Engin. Colo., 15 (1909-10), pp. 341, pls. 14*).—This report covers the existing physical and financial status of water supply and irrigation, road, and bridge works in Colorado in 1909-10, and includes the reports of division irrigation engineers, tabulated data from the reports of water commissioners, and a preliminary hydrographic report of the Yampa Basin. A large amount of tabulated discharge data from hydrographic investigations of the principal rivers of the State is presented.

**First biennial report of the State Road Commission of Utah, 1909-10** (*Bienn. Rpt. State Road Com. Utah, 1 (1909-10), pp. 70, pls. 21, figs. 4*).—This report, embodying reports of the 4 state road commissioners, states the progress of road improvement and construction in Utah in 1909-10, discusses the methods in use, gives a detailed account of the cost in each county, and makes recommendations for modifying the road statutes of the State relative to methods of improvement, construction, and administration.

The combined reports of all counties show that during 1909-10, 125,424 miles of road have been graded, surfaced with gravel or stone, or reconstructed of sand clay at a total cost of \$100,631.

**Preliminary report on the road materials and road conditions of Oklahoma, L. C. SNIDER** (*Okl. Geol. Survey Bul. 8, 1911, pp. XIII+191, pls. 12, figs. 26*).—This bulletin describes the meteorology, geography, and rock formations of Oklahoma, the general conditions and road laws, the distribution of road materials throughout the State, and the physical and chemical properties of road materials, and discusses the financial and social advantages of good roads in the different localities.

The construction and maintenance of earth and sand-clay roads are discussed under the subheads of location, surface and underdrainage, bridges and culverts, and machinery used. Paved roads are discussed under the subheads of macadam, brick, stone-block, and bitumens. The distribution of road materials is given by counties, and their distribution and the road conditions are discussed by dividing the State into 3 districts, the eastern district, the western district, and the southern or cretaceous district. The road materials of the State are classified in general as sand, clay, gravel, bitumens, coal-mine clinkers, igneous, sedimentary, and metamorphic rocks.

**Use of bitumens for roads, A. H. BLANCHARD** (*Municipal Jour., 32 (1912), No. 20, pp. 750-753*).—This is a paper read before the American Association for the Advancement of Science. A review is given of the use of bituminous mate-

rials in the construction and maintenance of American highways during 1911, discussing the extent of use, surface treatment, the penetration method, and bituminous concrete.

**Construction of country roads** (*Missouri Bd. Agr. Mo. Bul., 10 (1912), No. 3, pp. 78, figs. 55*).—This bulletin discusses road contracts, costs of plans, surveys, etc., the construction and cost of earth, sand, sand-clay, chert, rock and gravel, bituminous, concrete, and brick roads, and the methods and cost of maintenance.

**General forms for specifications and contracts, roads and culverts, 1912** (*Missouri Bd. Agr. Mo. Bul., 9 (1911), No. 10, pp. 38*).—This pamphlet contains suggested forms and other data for specifications and contracts relating to highway work.

**Electric power on the farm, A. SHANE** (*Iowa State Col. Engin. Expt. Sta. Bul., 10 (1911), No. 1, pp. 63, figs. 36; abs. in Gas Engine, 14 (1912), No. 5, pp. 244-246, figs. 2*).—It is the purpose of this bulletin to outline an electric system of general application to the farm and to discuss in some detail a particular installation under certain assumed farm conditions.

It is stated that on an average sized farm without the advantages of water power or a nearby transmission line, a gasoline engine offers the most advantages for driving the generator, chief of which are the little attention required and the fuel economy. Some electrical facts are stated, a few general instructions are given relative to installation, wiring, daily operation, ordering and testing apparatus, and computing operating costs. The general advantages of electric power on the farm are pointed out, such as flexibility in application to farm buildings, the independence of the farmer to outside help and weather conditions, and safety, easy care, easy control, and economy of electric machinery. The estimated cost of a power plant consisting of a 10-horsepower gasoline engine, 6 kilowatt generator, switchboard, and a 50-cell storage battery with accessories is \$1,017, and of the entire installation, including house, outbuilding, and outside apparatus is \$1,486.50.

**Experiments on the application of electricity to agriculture** (*Jour. Soc. Agr. Brabant et Hainaut, 57 (1912), No. 18, pp. 203, 204*).—Results of investigations are given showing the electric power required for driving different agricultural machines.

**A review of investigations of the international congress on the application of electrical energy, P. LECLER** (*Bul. Soc. Agr. France, 1912, May 1, pp. 445-456*).—The production, transmission, and utilization of electrical energy are dealt with, the bulletin discussing more especially the use of electricity in agriculture for electroculture and driving farm machinery, from both the technical and economic points of view.

**A novel and efficient farm power plant, E. S. ESTEL** (*Kimball's Dairy Farmer, 10 (1912), No. 8, p. 275, figs. 2*).—The author describes a farm water-power plant, consisting essentially of a small concrete pressure dam, having an 8-ft. head, a 9-ft. overshot water wheel, a small power house, transmission line, and house and outbuilding installations of motors, lights, etc. The total cost is given as a little less than \$400.

**Use of dynamite on the farm** (*Philadelphia, 1911, pp. 112, figs. 53*).—This pamphlet gives a large amount of data dealing with the use of dynamite on the farm, including directions for the use of this explosive in land clearing, digging drainage ditches, road grading, excavating for foundations, cellars, walls, post holes, etc., subsoiling and plowing, orchard cultivation, and for breaking up ice gorges, log jams, and log rollways.

**The hydraulic ram, W. C. DAVIDSON** (*Missouri Bd. Agr. Mo. Bul., 10 (1912), No. 2, pp. 36, figs. 19*).—This bulletin deals with the use of the hydraulic ram on the farm, describing the complete equipment and the theory of operation of

the hydraulic ram, stating the local conditions requisite, giving the necessary directions for installing a hydraulic ram, and discussing methods for computing the capacity of a hydraulic ram and the flow of streams or springs supplying the water. In addition considerable specific information is given regarding types of hydraulic rams, special installations, and methods of installing plants to satisfy individual conditions.

**A novel automobile for soil cultivation**, P. ÉVERARD (*Ann. Gemblour*, 22 (1912), No. 5, pp. 309-312, figs. 2).—A motor-driven machine for soil cultivation is described, consisting of a frame supporting a motor, a pair of adjustable rollers, which operates a double set of traveling plow shovels, and a pair of cutting discs in front of the shovels. The motor is connected to the other apparatus by a chain drive and can be disconnected and used for driving other farm machinery or for transportation.

**New spring-shovel cultivator** (*Wiener Landw. Ztg.*, 62 (1912), No. 27, p. 338, figs. 9).—A cultivator is described which has spring beams for its shovels as a protection against breaking the beam by striking roots, stones, etc.

**The binder engine**, E. B. SAWYER (*Nebr. Farmer*, 44 (1912), No. 18, p. 503, fig. 1).—Attention is called to the use of a light weight all-purpose engine for driving the mechanism of a binder. This engine is attached to the rear of the machine with brackets and operates the whole mechanism of the binder by means of a special drive chain connection. The drive wheel of the binder can be disconnected and this results in a great saving of horses.

**Land dragging in good cultivation**, J. JENSEN (*Masch. Ztg.*, 10 (1912), No. 8, pp. 92-94, fig. 1).—The need of dragging the fields during the spring ground breaking, thereby smoothing the ridges and breaking the clods, is pointed out, and a drag is described which is suitable for a road drag, land drag, or manure spreader. This drag is constructed of 2 wooden beams about 5 ft. apart connected by an iron rod framework to each of which is attached an iron band drag blade.

**Test of a grain cleaning and sorting machine**, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1912), No. 1, pp. 115-129, table 1, pl. 1, fig. 1).—This article gives a description of the operation and mechanical details of a machine for the cleaning, drying, and sorting of grain, and gives the methods and a table of results of tests. The grain is cleaned and dried by fan action and is separated into 3 different weights by the centrifugal action of a revolving drum. A mathematical discussion of the centrifugal action on the different weights of the grain is given, and with it a section of the centrifugal drum and plans showing the details and dimensions of the machinery in general.

**The mechanical harvesting of cotton**, F. MAIN (*Jour. Agr. Trop.*, 12 (1912), No. 129, pp. 75-78).—A machine is described for the mechanical picking of cotton, consisting of a frame set on 4 wheels, supporting a 30-horsepower engine, which drives the picking machinery and is directly connected to the hind drive wheels. The cotton is picked by the action of steel teeth and fingers and is conveyed to sacks in the rear. It is claimed that from 8 to 10 acres of cotton can be picked in a day.

**Report of tests on a dairy refrigerator**, B. MARTINY (*Molk. Ztg. Berlin*, 22 (1912), No. 16, pp. 181-183, figs. 3).—This article describes and gives the results and conclusions of tests of a device intended for the quick cooling of fresh milk and cream. This device consists of a chest containing an ice box with sloping bottom, above which is a receiving basin for the milk and cream. This communicates with a drip or sieve basin from which the milk or cream runs down along the bottom side of the sloping ice chest in a thin stream. It is quickly cooled in its descent and is caught in a reservoir below.

The results of tests lasting 3 days show the weights of ice and salt and the time required to cool given quantities of milk and cream. The advantages of the device pointed out are that it is self-acting, its capacity is such that a considerable quantity of milk and cream can be cooled and stored for some time, it is simple in construction and operation, and its initial cost and cost of operation are relatively small.

### RURAL ECONOMICS.

Farms and farm property [in the United States] (*Bur. of the Census [U. S.] Bul. 13, pp. 20, figs. 3*).—This bulletin presents in final form the principal data pertaining to farms and farm property in the United States by States and geographic divisions for 1900 and 1910, and by geographic divisions for each census from 1850 to 1910, correcting and supplementing preliminary data (E. S. R., 25, p. 893).

The following table summarizes for the United States the principal facts regarding population, farms, and farm property for the years 1910 and 1900:

*Farms, farm land, and farm property of the United States.*

	1910 (April 15).	1900 (June 1).	Increase.	
			Amount.	Per cent.
Population.....	91,972,266	75,904,575	15,977,691	21.0
Urban population.....	42,623,383	31,609,645	11,013,738	34.8
Rural population.....	49,348,883	44,384,930	4,963,953	11.2
Number of all farms.....	6,361,502	5,737,372	624,130	10.9
Land area of the country.....acres..	1,903,289,600	1,903,461,760	-172,160	.....
Land in farms.....do.....	878,798,325	838,591,774	40,206,551	4.8
Improved land in farms.....do.....	478,451,750	414,498,487	63,953,263	15.4
Average acreage per farm.....	138.1	146.2	-8.1	-5.5
Average improved acreage per farm.....	75.2	72.2	3.0	4.2
Per cent of total land area in farms.....	46.2	44.1	.....	.....
Per cent of land in farms improved.....	54.4	49.4	.....	.....
Per cent of total land area improved.....	25.1	21.8	.....	.....
Value of farm property, total.....	\$40,991,449,090	\$20,439,901,164	\$20,551,547,926	100.5
Land.....	28,475,674,169	13,058,007,995	15,417,666,174	118.1
Buildings.....	6,325,451,528	3,556,639,496	2,768,812,032	77.8
Implements and machinery.....	1,265,149,783	749,775,970	515,373,813	68.7
Domestic animals, poultry, and bees..	4,925,173,610	3,075,477,703	1,849,695,907	60.1
Average value of all property per farm....	\$6,444	\$3,563	\$2,881	80.9
Average value of all property per acre of land in farms.....	46.64	24.37	22.27	91.4
Average value of land per acre.....	32.40	15.57	16.83	108.1

Increase in value of farm lands (*Conn. Farmer, 42 (1912), No. 16, p. 4*).—This article directs attention to the constant increase of land values in New England, attributing it to the increased demand for land from people who have lived in the West and are now seeking cheaper lands nearer better markets in the East.

Making the farm renter a farm owner, G. H. CUSHING (*Nat. Land and Irrig. Jour., 5 (1912), No. 5, pp. 1-6, figs. 6*).—It is noted in this article that the directors of the Canadian Pacific Railway Company have recently appropriated \$500,000 as an initial fund to be loaned to renters for the purpose of buying and settling lands in the Provinces of western Canada. The conditions incident to any loan are (1) that the applicant is married, (2) must have demonstrated his ability to operate a farm successfully, (3) must have enough money to pay one-tenth the purchase price of the farm and maintain his family for a year,

and (4) must personally inspect and select the land he buys. If he can meet these requirements the company will loan him as much as \$2,500 at 6 per cent interest for a period of 10 years.

**The condition of the agricultural workmen in Sweden** (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intel., 3 (1912), No. 2, pp. 207-222*).—This article notes that during the last quarter of the eighteenth century, the peasants formed on an average 63.4 per cent of the agricultural population in Sweden; the "base tenants," that is tenant farmers whose rent consists in a fixed number of days' labor for the proprietor, 12.1 per cent; the "backstugusittare" (occupiers of the smallest lots of land who are not bound to a fixed number of days' labor for the proprietor), and the "inhyeshjon" (persons who work without contract), 8.5 per cent; and the servants 16 per cent. A century later the peasants constituted about 55 per cent of the farming population, while the "base tenants" formed 15 per cent, the "backstugusittare" and "inhyeshjon" 14.2 per cent, and the servant class, 15.8 per cent. The rural population between 1751 and 1840 averaged 80 per cent of the total population, but in 1908 it was only 49.12 per cent. The cause of the variation is attributed to manufactures and emigration.

With the decrease of farm laborers there has been a noticeable increase in their wages, which is illustrated in the following table:

*Wages of the various classes of agricultural laborers.*

Years.	Annual ordinary wage of servants lodged and boarded by the master.		Annual wage of laborers on "mixed wage" (partly in kind and partly in money).		Daily wage in summer.		Daily wage in winter.	
	Men.	Women.	Men.	Women.	Men.	Women.	Men.	Women.
	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>	<i>Crowns.</i>
1871-1875.....	154	61	375	214	1.82	0.86	1.20	0.60
1881-1885.....	153	66	396	213	1.55	0.83	1.04	0.57
1891-1895.....	173	84	404	225	1.78	1.02	1.21	0.71
1902-1905.....	233	123	507	286	2.21	1.30	1.54	0.93
1909.....	287	158	626	390	2.66	1.57	1.89	1.15

Other notes and tables are given showing phases of the social and economic conditions of the laborers.

**Immigration and employment of Polish farm laborers in France** (*Bul. Off. Travail [France], 18 (1911), Nos. 11, pp. 1071-1081; 12, pp. 1210-1219*).—The continually increasing scarcity of agricultural laborers in France has given rise to the establishment of a number of agencies whose purpose is to secure such laborers from beyond the frontier and arrange for their employment. The special efforts of these organizations in France, in cooperation with the Polish societies, to attract Polish laborers have met with reasonable success. Most of the agencies arrange contracts which stipulate the wages the laborers are to receive. Men and women field laborers engaged by the year usually receive from 324 to 528 francs (\$62.53 to \$101.90), including food and lodging, and if the laborer renews his contract for a second year from 420 to 624 francs. The wages of young men and women range from 240 to 350 francs a year, according to their aptitude and age.

**Report of the Irish Agricultural Organization Society, Limited, for the year ending June 30, 1911** (*Rpt. Irish Agr. Organ. Soc., 1911, pp. 122*).—In this report it is shown that the growth of the cooperative movement among

farmers in Ireland has been steadily and satisfactorily maintained. There were 19 cooperative creamery societies formed during the year and 14 agricultural societies, making a total of 320 of the former and 168 of the latter. Cooperative credit banks increased from 234 to 237, and the total of cooperative societies from 835 to 905. Data are given showing the work of a number of individual societies. See also a previous note (E. S. R., 23, p. 795).

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statist. Crop Reporter, 14 (1912), No. 4, pp. 25-32, fig. 1*).—This number includes notes and statistics showing the condition of winter wheat and rye; the condition of farm animals April 1, and estimated losses for a period of years and for the year ended March 31, 1912, with comparisons; farm value of crops and products on dates indicated; range of prices of agricultural products at important markets; monthly receipts and stocks of eggs and poultry in the United States, temperature and precipitation statistics, data as to high prices and crop production, apple shipments for 1911, and a diagram indicating the yearly trend of the per capita production and price of imported farm products.

It is concluded that the world's production of the staple food products has been increasing at a rate faster than the increase of population, and that "the recent advances in the 'cost of living' are not due to scarcity or lessening of agricultural products."

**Agricultural statistics of Bengal for 1910-11** (*Agr. Statist. Bengal, 1910-11, pp. 77*).—Tables showing the total acreage, classification of areas, crops, and current fallows in each district of Bengal during the agricultural year ended March 31, 1911, are here presented.

## AGRICULTURAL EDUCATION.

**Provisions in the various Southern States for teaching agriculture**, E. R. KONE (*South. Ed. Assoc., Jour. of Proc., 22 (1911), pp. 525-532*).—This article presents data and observations as to provisions made by the federal and state governments for instruction in agriculture in the various Southern States.

It is noted that a majority of these States make special provisions for teaching agriculture either in the public schools or in special agricultural schools, as well as in the agricultural colleges. Other States have statutory provisions requiring such instruction in elementary or high schools, but make no special appropriations for it.

**What constitutes successful work in agriculture in the high school**, L. N. DUNCAN (*South. Ed. Assoc., Jour. of Proc., 22 (1911), pp. 532-536, pl. 1*).—The successful teacher in agriculture is here described as one who not only acquaints his pupils with truths and principles of soil formation, soil preparation, seed selection, cultivation, plant propagation, etc., but imbues them with the spirit of the subject and creates a desire for further study. A number of practical suggestions are presented showing the best methods for teaching agriculture and obtaining these desired and more lasting results.

**Training of teachers for secondary courses in agriculture**, A. C. MONAHAN (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 9-21*).—In discussing the need and demand for teachers in agriculture and what is being done toward training them, it is noted that in 1910 agriculture was taught in over 100 special agricultural schools, and as a separate subject in more or less complete courses in 140 private high schools and 1,800 public schools to over 37,000 pupils. In 36 of the agricultural colleges opportunities are now offered for students to fit themselves as special teachers of agriculture in secondary school work. They may usually elect courses in general education and agricultural pedagogy, or take a prescribed 4-year course offered for teachers of

agriculture. A few institutions give a course for graduates preparing to teach agriculture.

**The vocational agricultural school, with special emphasis on part-time work in agriculture.** R. W. STIMSON (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 22-53*).—This article discusses and illustrates in detail the work of the vocational agricultural school, as found, for example, in the congressional district schools of Georgia, the county agricultural schools of Wisconsin, or the state agricultural schools in undivided districts in a number of the States. Special emphasis is directed to the system of part-time work, where the pupil must spend part of the time required for his education in productive farm work, preferably at home, and part at the school, the work at both places being closely correlated and under the direction of the teacher.

A number of projects which might be taken up by such a school are outlined in detail and suggestions given for their proper execution.

**State-aided departments of agriculture in public high schools.** D. J. CROSBY (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 54-65*).—It is noted that Kansas, Louisiana, Maine, Maryland, Massachusetts, Minnesota, New York, North Dakota, Texas, Virginia, and Wisconsin have appropriated funds to encourage the teaching of agriculture in existing public high schools. A number of these have also provided for courses in home economics and farm mechanics. Brief statements are given showing the character and amount of state aid and the requirements to be met in the different States.

It is found that the advantage of state aid over the local initiative system is that it insures better equipment in the way of laboratories, special apparatus, land, etc., and provides better supervision, which can more easily be made expert than where everything concerning courses of study and methods of teaching is left to town or county superintendents. Experts have already been employed by 3 of the States to supervise the work in agricultural instruction.

**High school agriculture without state subsidy.** W. H. FRENCH (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 66-74*).—This paper deals largely with what has been done in agricultural education in those States which have not appropriated special funds or granted special subsidies to individual schools for the introduction of courses in agriculture, home economics, or farm mechanics. It is concluded that this work has already gone far enough to demonstrate that (1) there is an interest on the part of the people in agriculture as a subject of study; (2) agriculture correlates well with other science subjects; (3) intellectual power can be developed through it; (4) the lives of young men are redirected and turned toward agriculture; and (5) practical results in farming processes in the community are secured.

For further advancement of the work it is suggested that a greater interest be awakened in the public mind by extension and demonstration work; that the States grant special subsidies to the schools; and that the state institutions give special attention to the preparation of vocational teachers.

**Short courses and extension work for agricultural high schools in the South.** H. F. BURTON (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 75-82*).—This article describes the extension work of the Agricultural High School at Manassas, Va. Short winter courses lasting 6 to 8 weeks devoted to subjects of local agricultural interest have proved very successful, as have also illustrated lectures and demonstrations given in neighboring rural schools on many phases of agriculture. Interest has been aroused and efforts stimulated for a better and more permanent agriculture in the community.

**Short courses and extension work in agriculture for high schools in the North.** F. R. CRANE (*Yearbook Nat. Soc. Study Ed., 11 (1912), pt. 2, pp. 83-90*).—This article deals with short courses and extension work in agriculture

in high schools and special secondary agricultural schools in the northern portion of the United States, special reference being made to the agricultural schools of Wisconsin. It describes (1) short courses, including (a) a 15 weeks' course for boys who have had no training for farming, (b) a 2-year short course in dairying, (c) a farmers' lecture course, which includes a 16 weeks' young people's course usually during the winter, (d) a farmers' 1 week's school, and (e) institutes and summer tours; (2) extension work, consisting of demonstrations on the individual farm, and the organization of corn testing societies, grain growing associations, and social centers; (3) an information bureau, where the instructor answers personal inquiries, makes seed tests, Babcock tests, etc.; and (4) the distribution of publications.

**Practical aid to the school garden movement by the United States Department of Agriculture, SUSAN B. SIPE** (*Nature-Study Rev.*, 8 (1912), No. 2, pp. 51-53).—A brief account is given of the operations of the Office of Experiment Stations in promoting the theoretical side of the school garden movement, and of the Bureau of Plant Industry in promoting its practical side.

**The school garden as a center for the teaching of nature study, R. O. JOHNSON** (*Nature-Study Rev.*, 8 (1912), No. 2, pp. 54-61, figs. 4).—The author gives as one of the reasons why the school garden should be made the center for teaching nature study that "the child in the garden (a little world in itself) is placed on a battle ground of opposing natural forces which are identical in kind and behavior with those which he must necessarily meet in his subsequent life." It is also shown that garden work combines the serious and the pleasurable, makes the pupil stronger and more resourceful through the knowledge of his ability to deal with natural forces, furnishes a most potent motive for the learning of the formal lesson in nature study, enlists the interest of parents, furnishes easily accessible material for the nature study-lessons, and guaranties a closer relation of nature study with other subjects in the curriculum. Incidentally it teaches a number of exceedingly interesting and profitable lessons, such as respect for the man who works with his hands, a sense of ownership or proprietorship which tends to develop independence, strength, and self-respect, an appreciation of the value of money, cooperation and neighborliness, and habits of neatness and orderliness.

**School gardening, a fundamental element in education, B. J. HORCHEM** (*Nature-Study Rev.*, 8 (1912), No. 2, pp. 62-66, fig. 1).—The author considers that school gardening is fundamental in its relation to the physical and moral development of the child, and that a healthful and natural development will solve the social problems of the nation.

**The civic aspect of school gardens, LOUISE K. MILLER** (*Nature-Study Rev.*, 8 (1912), No. 2, pp. 74-77, fig. 1).—The author points out that school gardens may become radiating centers of great influence for civic improvement. She refers to the department of school gardens in Cleveland, where there are 107 school gardens of from 1 to 5 acres for normal, backward, defective, blind, crippled, and tubercular children, boys in the detention school for the juvenile court, a kitchen garden for the domestic science class, and a botanic garden. In the schools last winter 60 illustrated lectures were given by the curator of school gardens on various phases of gardening and crop production.

**Boys' potato clubs: How to grow the crop and organization, J. C. HOGENSON** (*Utah Sta. Circ.* 5, pp. 3-15).—Directions are given for growing and handling potatoes and for organizing potato clubs.

**Outlines in agriculture and home economics, E. T. FAIRCHILD** (*Торпка, Kans.: Dept. Pub. Instr.*, 1911, pp. 35).—The author indicates the necessary equipment, including soil and crop specimens, for instruction in agriculture,

offers suggestions to teachers, and outlines a course of study in agriculture based upon the Elements of Agriculture, by G. F. Warren (E. S. R., 21, p. 494), for class room instruction, and A Unit in Agriculture, by J. D. Elliff (E. S. R., 24, p. 293), for laboratory work. He considers that the subject can be presented satisfactorily in 3 recitation and 2 laboratory periods a week. The laboratory period should be double the class period and should come as the last exercise in the day, thus permitting the class to visit neighboring farms without returning to the school after the class period is over. A list of agricultural texts and reference books is included.

Outlines are also given of courses in home economics, a bibliography for students and teachers, and suggestions concerning equipment.

**Syllabus of illustrated lecture on the peanut: Its culture and uses, W. R. BEATTIE** (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 13, pp. 23*).—In this lecture, prepared for the use of farmers' institute lecturers, the author gives instruction on the soil and its preparation; crop rotation in peanut culture; planting, fertilizing, cultivating, harvesting, and marketing peanuts; varieties of peanuts; uses of peanuts as food, for the production of oil, and as stock feed; and cost of growing peanuts and returns. A list of 50 lantern slides to illustrate the lecture and a list of reference literature are appended.

**Syllabus of illustrated lecture on farm home grounds—their planting and care, S. W. FLETCHER** (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 14, pp. 16*).—In this lecture, prepared for the purpose of aiding farmers' institute lecturers in the presentation of this subject, the following topics are considered: A house and a home, farm buildings, outbuildings, valuable trees, neatness, what to plant, the lawn, walks, and drives, and what will it cost. A list of 51 lantern slides to illustrate this lecture is appended.

**Swine husbandry in Oregon, diversified crop production for the Oregon dry farmer, dairy cows and alfalfa, poultry production, J. WITCOMBE, E. L. POTTER, H. D. SCUDDER, F. L. KENT, and J. DRYDEN** (*Oregon Sta. Circ. 18, pp. 5-40, figs. 15*).—This circular, dealing in a popular way with the above subjects, was prepared for distribution on the farming demonstration train known as the Hog and Field Pea Special, and operated over the lines of the Oregon and Washington Railroad and Navigation Co., in conjunction with the Oregon College and Station.

### MISCELLANEOUS.

**Nineteenth and Twentieth Annual Reports of Oklahoma Station, 1910-11** (*Oklahoma Sta. Rpts. 1910-11, pp. 236, figs. 61*).—This contains the organization list, a report of the director on the work and publications of the station during the year, a financial statement for the fiscal years ended June 30, 1910, and June 30, 1911, brief outlines of work in progress, departmental reports, the experimental work of which is abstracted elsewhere in this issue, and reprints of Bulletins 86 to 92, Circulars 13 and 14, previously noted, Bulletin 93 noted on page 274 of this issue, and of press bulletins entitled The Melon Aphid, Experiments with Winter Wheat, Fall Plowing as a Means of Insect Control, Registration of Live Stock, How to Plant a Tree, The Melon Louse and Disease of Chinch Bug, Broom Corn, The San José Scale, and Alfalfa.

**Report of the director for the year ending June 30, 1911, F. B. MUMFORD** (*Missouri Sta. Bul. 101, pp. 201-236, figs. 2*).—This contains the organization list, a report of the director on the work and publications of the station, and a financial statement for the fiscal year ended June 30, 1911.

**Index, Bulletins No. 83-96** (*Missouri Sta. Index Buls. 83-96, pp. 9*).

## NOTES.

---

**Alabama College and Station.**—F. E. Lloyd, professor of botany and botanist, has been appointed Macdonald professor of botany in McGill University, and will enter upon his new duties September 10.

**Arkansas University.**—J. N. Tillman has resigned as president.

**Colorado Station.**—R. S. Herrick, field horticulturist at the Grand Junction substation, has accepted the position of horticulturist in extension work at the Iowa College, and entered upon his new duties August 15.

**Illinois University and Station.**—A new four-year course in agriculture has been outlined, whereby the first year's work and one-half that of each semester of the second year will be required. The remaining time will be available for specialization in soils, crops, agricultural teaching, horticulture, farm mechanics, dairying, or animal husbandry.

William Dietrich, assistant professor of swine husbandry, has resigned to become superintendent of a stock farm. B. R. Rickards has resigned to engage in commercial work, and will be succeeded as head of the division of municipal and sanitary dairying by H. N. Parker.

**Michigan College and Station.**—Leo M. Geismar, formerly superintendent of the substation at Chatham, has been transferred to extension work in the Upper Peninsula, with headquarters at Marquette.

**Nevada University and Station.**—L. T. Sharp, formerly connected with the soils laboratory of the California Station, has been appointed to have charge of soil research work in the station and to give instruction in soils in the university.

**South Dakota College and Station.**—Dr. Edgar W. Olive, professor of botany and botanist, has been appointed curator of the Brooklyn Botanic Garden, to have charge of the department of public instruction and also of work in plant pathology, this becoming effective September 1. C. M. Woodworth, instructor in agronomy; J. C. Hart, also a 1912 graduate, as superintendent of the Chatham of Plant Industry of this Department.

**Virginia College and Station.**—Press reports announce the resignation of President Barringer, and state that he has been asked to remain until July 1, 1913. Recent appointments include A. W. Drinkard, jr., who has been on leave of absence for two years at Cornell University, as associate horticulturist, beginning October 1; A. N. Hodgson, a 1912 graduate of the college, as assistant in agronomy; J. C. Hart, also a 1912 graduate, as superintendent of the Chatham substation; W. G. Harris as assistant chemist; and George W. Chappellear as assistant in agronomy in the college. T. B. Hutcheson, superintendent of plat work, has been granted leave of absence beginning October 1 to pursue graduate study at Cornell University. William Kerr, assistant animal husbandman, has resigned to engage in practical work.

## CONTENTS OF VOL. XXVII, NO. 4.

	Page.
Editorial notes:	
The agricultural appropriation act of 1912-13 .....	301
Recent work in agricultural science.....	309
Notes.....	397

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The transformation of malic acid to sugar by the maple, Bloor.....	309
The chemical composition of the substances contained in the birch, Grasser....	309
The occurrence of formyl and acetyl groups in lignin, Cross and Tollens.....	310
Plant coloring matters, Oesterle.....	310
In regard to chlorophyll, Kautzsch.....	310
Colloid chemistry of food and condiments, Bechhold.....	310
Yearly reports on the examination of foods and condiments, Beckurts et al....	310
Determination of ustillaginous spores in wheat bran, Gröh.....	310
Inspection of cyanogenetic haricot beans in France, Gautier and Bordas.....	310
Calculating water in canned tomatoes and detection of added water, Congdon..	310
Osmotic activity in the egg of the common fowl, Greenlee.....	311
Value of guaiac tincture test for differentiating raw from boiled milk, Rievel..	311
Better cream through grading.—A new butter moisture test, Benkendorf.....	311
The determination of moisture in butter, Rivett.....	312
Refraction of the nonvolatile acids of butter, Van Raalte and Lichtenbelt....	312
A modified butyrometer for determining the fat content of cheese, Van Gulik..	312
Use of reversed filtration and Weender methods for crude fiber, Schröder.....	312
A micro-chemical test for digestible cellulose in feces, Amann.....	312

	Page.
The canning of foods, Bitting.....	313
Peach drying in Chile.....	313
[Converting low-grade vinegar into good vinegar], Sackett.....	313
Bacteria interfering with the malting process, Güssow.....	313
The oil industry in Algiers, Foussat.....	313
Antiseptic effect of creosote and other oils for preserving timber, Weiss.....	314
Maize straw; its use for the manufacture of paper and fodder, Dorner.....	314
The sugar content of maize stalks, Blackshaw.....	314
The microscopy of certain paper pulps, Hanausek.....	315
The microscopy of paper made from cane bagasse, Hanausek.....	315

## METEOROLOGY—WATER.

Meteorology, Milham.....	315
On the estimation of humidity in agricultural meteorology, Nerucev.....	315
Bulletin of the Mount Weather Observatory.....	316
Monthly Weather Review.....	316
The weather of the past agricultural year, Brodie.....	316
The weather of Scotland in 1911, Watt.....	316
The chemistry of rare rain.....	317
The fertilizing value of rain and snow, Shutt.....	317
Observations on the ground-water level, Vogen.....	317
Report of progress of stream measurements for the calendar year 1910, Saunder..	317
The water supply of farm homesteads, Shutt.....	317
Sterilization of drinking water by ultraviolet light, Courmont.....	317
Purification of water by infusoria, Stokvis and Swellengrebel.....	317
Sewage pollution of interstate and international waters, McLaughlin.....	318
The Berlin sewage farms (43,009 acres), Roehling.....	318
Irrigation with sewage.....	318
The struggle with sewage sludge, Naylor.....	318

## SOILS—FERTILIZERS.

Soils of the eastern United States and their use, XXXVI-XXXVII, Bonsteel..	319
The soils of Prince George's County, Bonsteel.....	319
Has the fertility of land in India decreased? Coventry.....	319
Modern soil investigations, Björlykke.....	320
On the degree of consistency and stiffness in soils, Atterberg.....	320
Corrections in physical science, Narayana Rao.....	320
The moisture content of packed and unpacked soils, Shutt.....	320
Soil tank investigations, Blair.....	320
A study of alkali soils, Ladd and Johnson.....	321
Plant food lost in drainage from uncultivated peat soils, von Feilitzen et al....	321
Regarding humus acids of Sphagnum turf, Odén.....	322
The influence of carbon upon nitrification, Clark and Adams.....	322
The present status of soil inoculation, Kellerman.....	322
Azotogen, nitragin, and natural inoculating soil, Kühn.....	322
Azotogen, nitragin, or inoculating soil, Teisler.....	322
Inoculation experiments with nitragin for legumes, Shutt.....	322
Nitrogen enrichment of soils through the growth of clover, Shutt.....	322
Increasing the ammonia fixing power of soils, Lemmermann and Fresenius....	322
The active potash of the soil and its relation to pot experiments, Fraps.....	323
The feeding of plants with mineral matter through the leaves, Hiltner.....	324
Cooperative fertilizer tests on clay and loam soils, Abbott and Conner.....	324
The fixation of atmospheric nitrogen by the use of aluminum nitrid, Marre...	325
Phosphoric acid fertilization and moor culture, von Feilitzen.....	325
The fertilizing value of superphosphate, Klinkerfues.....	325
The use of phosphatic fertilizers in France, Hitier.....	326
The production of phosphate rock in 1911, Van Horn.....	326
The business aspect of the kelp proposition, Dewey.....	326
Potash lime, its preparation and use in agriculture, Möller et al.....	326
Carriers of lime, Ames.....	326
Sulphur as a fertilizer, Heraud.....	326
Some results obtained from the use of catalytic fertilizers, Bertrand.....	327
Argentina guano, Marotta.....	327
Fertilizing value of sewage sludge at Madison, Wisconsin.....	327
Commercial fertilizers, Jones, jr., et al.....	327

	Page.
Commercial fertilizers, Hite and Kunst.....	327
Fertilizing materials, Shutt.....	327
An act to regulate the sale of commercial fertilizers.....	327
The American fertilizer handbook, 1912.....	327
The world's consumption of fertilizers.....	328
Mineral fertilizers in Spain.....	328
Artificial fertilizer trade.....	328

## AGRICULTURAL BOTANY.

A text-book of botany.—II, Ecology, Coulter, Barnes, and Cowles.....	328
Types of British vegetation, edited by Tansley.....	328
The practice of agricultural bacteriology, Löhnis.....	329
One thousand fungi, McIlvaine and Macadam, revised by Millsbaugh.....	329
Seeds and plants imported from April 1 to June 30, 1911: Inventory No. 27....	329
Deciduous rootlets of desert plants, Cannon.....	329
Setting of fruit and seed by cultivated plants, Zacharias.....	329
Low temperatures with exclusion of air and viability of seeds, Clemens.....	329
Results of the germination of seed subjected to various solutions, Lesage.....	330
The effects of caffeine upon the germination and growth of seeds, Ransom.....	330
Water and light as factors in vegetation, Pfeiffer, Blanck, and Flügel.....	330
Relation of daily transpiration to the water content, Livingston and Brown....	331
Stimulation movements of plants, Pringsheim.....	331
Nitrogen assimilation under sterile conditions, Petrov.....	331
The assimilation of nitrates in plant cells, Loew.....	332
The physiological function of magnesia in green plants, Bernardini and Morelli.....	332
Injurious effects of illuminating gas upon greenhouse plants, Wilcox.....	332
The tarring of roads and its effect on the neighboring vegetation, Gatin.....	333
Chemical protection of plants against freezing, I, Maksimov.....	333
A new method of cultivating some higher plants in sterile media, Combes.....	333

## FIELD CROPS.

[Field crops work at the Canadian stations and farms in 1910], Saunders et al..	334
[Field crops at the Florida Station], Scott.....	335
Report on the agricultural stations in Central Provinces and Berar, 1910-11....	336
[Fertilizer and variety tests], Thompstone.....	337
[Crops and green fodder in winter], Marks.....	337
Cooperative experiments of the department of agronomy, Miller and Hutchison.....	337
Emergency crops for overflowed lands in the Mississippi Valley, Knapp.....	337
Top dressing grass lands.—The sowing of red clover, Grantham.....	337
Separation of Swiss cereals into different types, Martinet.....	338
[Small grain varieties recommended].....	338
Alfalfa seed production, Westgate, McKee, and Evans.....	338
[Alfalfa seed in color, germination, and structure], Mackinnon.....	338
Second generation of the cross between velvet and Lyon beans, Belling.....	338
Corn production, Roberts and Kinney.....	339
Cotton and cotton culture, Churchill and Wright.....	340
Experiments with varieties of cotton, Harper and Tarbox, jr.....	340
The seeding of cowpeas, Miller.....	340
Thousand-headed kale and marrow cabbage, Chapin.....	340
Changes in the oat plant as it approaches maturity, Keitt and Tarbox, jr.....	340
The assimilation of phosphorites by oats and buckwheat, Sazanow.....	340
A new basis for estimating the value of potatoes, Zolla.....	341
Rye selection at Svalöf, 1910, Ljung.....	341
The quality of grain in the season 1910-11, Schaffnit.....	341
The sugar beet in 1911, Saillard.....	341
Biometrical studies of tobacco varieties, Rinaldi.....	341
Early fertilization of tobacco seedlings and later development, Montemartini..	341
Field experiments with wheat, Ditzell.....	342
The effect of carbon bisulphid on the germination of wheat, Morettini.....	342
Plant breeding methods, Hummel.....	342
[Seed tests], Hammar.....	342
Studies with dodder.—I, Germinability; II, Infection studies, von Degen.....	342
Michigan weeds, Beal.....	343

## HORTICULTURE.

	Page.
[Horticultural work at the Canadian stations in 1910], Macoun et al.....	343
Beginners' guide to fruit growing, Waugh.....	344
Horticultural statutes of the State of California, 1912.....	344
Combating orchard and garden enemies, Chandler.....	344
Ampelography of the Crimea, Korshinsky.....	344
Statistics on the production of grapes and olives in 1911.....	344
Citrus experiments, Blair.....	344
A practical method of artificially ripening Japanese persimmons, Lloyd.....	344
Large scale experiments on processing Japanese persimmons, Gore.....	344
Covering almond trees for frost protection, McAdie.....	345
Cranberry bog management for Wisconsin, Malde.....	345
Ginseng and golden seal growers' handbook, Koehler.....	346
Status and prospects in ginseng industry, Kains.....	346
Lavender cultivation, Knight.....	346
Handbook of trees, shrubs, vines, and herbaceous perennials, Kirkegaard.....	346
Lawn soils and lawns, Schreiner, Skinner, Corbett, and Mulford.....	346

## FORESTRY.

Forest conditions in the northern Ozarks of Arkansas, Bennett.....	346
Notes on forest conditions in northwestern Nebraska, Pool.....	346
Trees of Omaha, Fullaway, jr., and Chapline, jr.....	346
The catalpas and their allies, Garman.....	346
Utah juniper in central Arizona, Phillips and Mulford.....	347
Quebracho wood and its substitutes, Mell and Brush.....	347
Cinchona in Java from 1872 to 1907, Van Gorkom, edited by Hooper.....	347
Castilla and its culture, Olsson-Seffer.....	347
A test of daily versus alternate daily tapping of Hevea, Van Hall.....	347
Notes on bark structure, Krueger.....	347
A sample dichotomous table for determination of coniferous species, Pardé.....	347
Operation of a Prussian seed extracting establishment, Recknagel.....	347
The economic returns from forestry, Martin.....	347
Assistance to private owners in the practice of forestry.....	348
Some permanent sample plat studies, Korstian.....	348
Method for determining effects of forests upon run-off in the Rockies, Garver.....	348
Effect of fires on trees and reproduction in southern New England, Buttrick.....	348
The need of fire protection in the Tropics, Fischer.....	348
Rainfall a factor of tree increment, Davis.....	348
Notes on winterkilling of forest trees, Hartley.....	348
A new method of constructing volume tables, Bruce.....	348
Sand blast tests of New South Wales timbers, Warren.....	348
On the durability of railroad ties, Havelik.....	348
Quantity and quality of creosote found in piles after long service, Bateman.....	348

## DISEASES OF PLANTS.

[Report of the botanist on plant diseases in 1910], Güssow.....	349
Report of plant pathologist, Fawcett.....	350
Report of plant physiologist, Floyd.....	350
Notes on some mildews, Foëx.....	351
The specialization of <i>Uromyces caryophyllinus</i> , Fischer.....	351
Corrosive sublimate as a treatment for winter grains, Hiltner and Gentner.....	351
A wheat head disease, Fron.....	351
Leaf roll of potato.....	351
The wart disease of potatoes, Middleton.....	351
Some fungus diseases of the prickly pear, Wolf.....	352
Beet nematodes ( <i>Heterodera schachtii</i> ), Fuchs.....	352
Tumor formation in sugar beets, Spisar.....	352
Melon or cucumber canker, Middleton.....	353
Collar blight and other collar and root diseases of the apple, Waite.....	353
Pear blight control, Gammon.....	353
American gooseberry mildew, Middleton.....	353
The rusts of wild grapes in India, Butler.....	353
A coconut disease of Mexico, Olsson-Seffer.....	353
A disease of Anthemis, Blin.....	354

	Page.
A new <i>Marssonina</i> on dill, Hegyi.....	354
Sweet pea diseases.....	354
The war on the chestnut blight, Detwiler.....	354
Protection of woods by solutions from injurious fungi, Rumbold.....	354
Studies in dry rot.—I, The biology of <i>Coniophora cerebella</i> , Wehmer.....	355

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Game, aquatic, and rapacious birds in relation to man, McAtee and Beal.....	355
Migration of the Pacific plover to and from the Hawaiian Islands, Henshaw.....	355
Third annual report of the state ornithologist, Forbush.....	355
Digest of the game, fish, and forestry laws, 1911, edited by Kalbfus.....	355
Notes on the mammals of the Lake Maxinkuckee region, Evermann and Clark..	355
Destruction of rats in Japan.....	356
Text-book of protozoology, Doflein.....	356
Observations upon the morphology of parasitic and cultural amoebae, Craig.....	356
Report of the dominion entomologist, Hewitt.....	356
Report of field entomologist, Weldon.....	356
Report of entomologist, Berger.....	356
Combating scale and other insects, Trabut.....	357
The insect enemies of the prickly pear, Tryon.....	357
Combating the insect enemies of the olive.....	357
The enemies of the coconut palm.....	357
Termite studies, Holmgren.....	357
Grasshopper disease, Sackett.....	357
The propagation of the Mexican locust epizootic in Argentina, D'Herelle.....	357
The destruction of locusts by Herelle's method, Guérin.....	358
How to fight the pear thrips, Merrill.....	358
Scale insects and black blight, Auchinleck.....	358
European elm scale in California, Woodworth.....	358
African scale insects, Lindinger.....	358
Control of the codling moth in Arizona, Morrill.....	358
Revision of the oriental Tipulidæ with descriptions of new species, Brunetti....	358
A revision of oriental species of the Tabanidæ other than <i>Tabanus</i> , Ricardo.....	359
The Mediterranean fruit fly in the Hawaiian Islands, Carnes.....	359
Another mango pest in the Philippines, Wester.....	359
A note on the habits of the narcissus fly, Chittenden.....	359
First annual report of the state inspector of apiaries, Gates.....	359
Pollination of red clover by bumblebees, Lindhard.....	359
The natural history of the solitary wasps of the genus <i>Synagris</i> , Roubaud.....	359
The Ichneumons of Great Britain, Morley.....	359
A study of the biology of <i>Limnerium validum</i> , Tiberlake.....	359
The southern corn root worm in South Carolina, Thomas.....	360
Locomotion of the larva of <i>Calosoma sycophanta</i> , Burgess.....	360
Collecting ladybirds (Coccinellidæ) by the ton, Carnes.....	361
Notes on the Ixodidæ of Brazil, De Beaufort, Aragão.....	361
Notes on <i>Rhipicephalus</i> , with the description of new species, Warburton.....	361
Notes on ticks.—II, New species, Nuttall.....	361

## FOODS—HUMAN NUTRITION.

Report of the commission on the cold storage of food and food products.....	362
Supplying a large city with foodstuffs, Lange.....	363
The preparation of Westphalian hams.....	363
A protein body in Liebig's meat extract, Mays.....	363
The chemical composition of human milk as shown by recent analyses, Schloss..	363
Influence of age on wheat and flour, Shutt.....	363
Analysis and composition of honey from Cuba, Mexico, and Haiti, Bryan et al..	363
The nitrogenous constituents of fungi, Reuter.....	364
The presence of glutaminic acid in preserved tomatoes, Monti.....	364
[Food inspection and other pure food and drug topics], Ladd and Johnson.....	364
Notice of judgment.....	365
Food values—practical tables, Locke.....	365
Directions for preparing diet for health and disease, Reymann.....	365
[Artificial feeding, poverty, and infant mortality], Greenwood and Brown....	365

	Page.
Influence of extractives of meat on digestibility of vegetable food, Wolff.....	365
Effect of polished rice on the nitrogen and phosphorus of the brain, Funk.....	365
The physiological effect of benzoic acid and sodium benzoate, Gerlach.....	365
Calorimetric observations on man, Macdonald.....	367
A new calorimeter for small warm-blooded animals, Hill.....	367

## ANIMAL PRODUCTION.

General review of zoology, I, Caullery.....	368
The mechanistic conception of life, Loeb.....	368
The comparative physiology of response in animals, von Uexküll.....	368
Behavior of chicken sarcoma implanted in embryo, Murphy and Rous.....	368
The structure of reproductive organs of domesticated animals, Schmaltz.....	369
The function of the accessory reproductive glands in male mammals, Iwanov.....	369
The origin of sexual differences, Kammerer.....	369
Recent work on the determination of sex, Doncaster.....	369
Studies on hair and hair colors in domesticated animals, Wiegmann.....	369
Hair and the hair coat system of mammals, Toldt, jr.....	369
Comparative anatomy of supernumerary digits in ungulates, Share-Jones.....	369
The continuous origin of certain unit characters, Osborn.....	369
The inconstancy of unit characters, Castle.....	369
Mendelian proportions and the increase of recessives, Ramaley.....	370
Mendel's laws and stock breeding, Wilson.....	370

# EXPERIMENT STATION RECORD.

VOL. XXVII.

SEPTEMBER, 1912.

No. 4.

The act making appropriations for the support of the Federal Department of Agriculture for the fiscal year ending June 30, 1913, is noteworthy for its continuance of the general policies of recent years. Despite a general tendency for retrenchment wherever possible in the public service, no line of work now under way by the Department has been discontinued. The great majority of its projects are maintained on their present basis. Opportunity for additional development has been provided in several cases, and a few new undertakings have been authorized. This outcome may be regarded as especially significant and encouraging, indicating a sustained interest by the people of this country in the work of the Department as a whole, and a widespread realization of the importance of its uninterrupted continuation.

The new appropriation act was not passed until August 10. During the interval of nearly six weeks which followed the termination of the preceding fiscal year on June 30, the maintenance of the Department, as well as of most other branches of the Government, was provided for by the passage of special resolutions extending the appropriations, under certain restrictions, on the basis of the act of the previous year.

The aggregate carried by the act is \$16,651,496, which exceeds that of any year except the one immediately preceding, when the total reached was \$16,900,016. In the absence of serious forest fires, however, the reduction as compared with 1912 will be more or less nominal, since there has been a diminution from \$1,000,000 to \$200,000 in the fund for fighting forest fires in the National Forests in cases of extraordinary emergency. If this item is disregarded, there is an actual increase of \$551,480 for the routine work of the Department, and a considerable increase over the original estimates submitted.

In its general form the law conforms closely to its immediate predecessor, but in addition to the provisions of a routine nature it contains considerable new legislation. This is particularly the case as

regards the National Forests. The Secretary of Agriculture is directed to select and segregate as soon as practicable all lands within the boundaries of such forests that may be opened to settlement and entry under the homestead laws applicable thereto. The sum of \$25,000 is appropriated for this purpose, together with \$35,000 additional for the survey and listing of lands within the reserves chiefly valuable for agriculture. Additional provision is also made for timber sales to settlers. The purchase of lands under the Appalachian Forest Reserve act of 1911 was aided by legislation making available until expended any balances remaining on June 30, 1912, and in succeeding years, and a new appropriation of \$32,590 was granted for the maintenance of forest lands acquired under that act.

It will be recalled that by a clause in the appropriation act of May 23, 1908, 25 per cent of all receipts from each forest reserve is paid to the State in which the reserve is situated, to be expended as the legislature may prescribe for the benefit of the public schools and public roads in the locality. An additional 10 per cent of the receipts is now to be expended by the Secretary of Agriculture for the construction and maintenance of roads and trails within the respective National Forests in cooperation, if deemed practicable, with the State authorities.

By another new clause the sanitary provisions of the meat-inspection act of 1906 are extended to include renovated-butter factories. The Department is authorized to undertake experiments in the breeding of horses for military purposes, and to study the rearing of fur-bearing animals. A national game preserve is established within the Wind Cave National Park, in South Dakota, as a permanent range for a herd of buffalo to be presented to the United States by the American Bison Society, as well as for other native game animals, and an initial appropriation of \$26,000 is made for buildings, fencing, and the procurement of a water supply. A similar reserve of 2,500 acres is provided in Wyoming as a winter refuge for elk, \$45,000 being made available for the purchase of land and its equipment and maintenance.

Provision is again made for the investigation of the cost of food at the farm and to the consumer. In addition the Secretary is directed to collect information as to cooperative and other systems of marketing farm products in vogue in this country, and to make recommendations regarding further investigations of these and related questions.

An appropriation of \$10,000 is provided for an exhibit by the Department illustrative of investigations, products, and processes relating to farming in the subhumid region, to be made at the next International Dry Land Congress, which will be held at Lethbridge,

Alberta, in October. An exhibit is also to be prepared for the Fifth International Corn Exposition, to be held at Columbia, S. C., from January 27 to February 9, 1913.

The continued spread of the chestnut bark disease, for combating which \$5,000 was granted last year, has led to an increase of the fund to \$80,000. It is provided that \$10,000 of this sum is to be expended in the study of the relation of insects to the disease.

Provision for rental of quarters in the District of Columbia is made in a special clause carrying \$95,329. A portion of this sum will be utilized for the rental of a modern six-story office building now nearing completion on ground practically adjoining the present laboratory buildings of the Department. The first four stories of this structure will be divided among several offices of the Bureau of Plant Industry which do not require laboratory facilities, and the remainder will be occupied by the Office of Experiment Stations, housing all of its activities except its nutrition investigations.

About one-tenth of the total appropriation is allotted to the Weather Bureau, which receives \$1,619,680, an increase of \$19,430. There is considerable readjustment of the various allotments, but it is expected that the increase will permit of additional employees and the more complete distribution of storm and frost warnings in connection with the protection of orchards and other crops. For the investigations in climatology and meteorology the previous allotment of \$120,000 is reduced to \$115,000.

The Bureau of Animal Industry also receives an enlarged appropriation, its total being \$1,670,316. This, of course, does not include the permanent appropriation of \$3,000,000 per annum provided for the Federal meat inspection in the act of 1906. The fund for inspection and quarantine work is slightly increased to provide for the maintenance of the recently acquired quarantine stations at the ports of Baltimore and Boston, and for the further extension of the work in the eradication of tuberculosis in domestic animals. The Dairy Division will receive \$177,900, this including a net increase of \$28,500 for the maintenance of the dairy work at the experimental farm at Beltsville, Md., the extension of the market milk and other educational work, and studies of the utilization of creamery by-products.

The allotment for cooperative experiments in animal feeding and breeding is doubled, the increase of \$50,000 being in connection with the new project for experiments in breeding horses for military purposes. Increasing difficulty is reported by the War Department in securing remounts of the special types desired. Under the plan proposed the Government will purchase stallions of suitable type for free service in a number of districts, retaining under these conditions an option for the War Department on the foals. The remaining ap-

appropriations of the Bureau are continued on essentially the present basis, \$52,180 being available for other investigations in animal husbandry, \$250,000 for the cattle tick eradication campaign, \$78,680 for the study of animal diseases, and \$16,500 for additional buildings at the Bureau farms.

The largest increase accorded to any bureau was received by the Bureau of Plant Industry, the total appropriation being \$2,323,580, as compared with \$2,061,686 in 1912. There is some readjustment of administrative details, but the majority of the projects are provided for much as before. The Congressional seed distribution, which is continued on the usual basis, will receive \$226,940, and \$58,740 will be available for the introduction of seeds and plants from foreign countries. There is also an appropriation of \$52,430 for the testing of special seeds and plants, of which \$40,000 is an increase for the purchase and distribution of drought-resistant field seeds, and \$23,530 is provided for seed inspection. The pathological work of the Bureau receives specific allotments of \$117,185, in addition to the appropriation for the chestnut bark disease already referred to.

The testing and breeding of fibrous plants has been extended to include work with flax straw in cooperation with the North Dakota College. Grain production and handling will receive \$136,405. The expenditure of \$8,000 for the purchase of spinning machinery is authorized in connection with studies of the ginning, handling, and grading of cotton. Other allotments are \$86,015 for pomological work, \$30,380 for studies in crop physiology, \$26,145 for soil bacteriology and plant nutrition investigations, \$33,300 for crop acclimatization work, \$46,930 for work with drug plants, poisonous plants, and tea culture, \$10,010 for crop technological and fiber plant studies, \$15,655 for physical investigations, \$26,630 for studies of methods of tobacco production and handling, \$20,000 for the improvement of forage crops, \$35,795 for work with sugar-producing crops, \$21,930 for grazing investigations, and \$49,930 for the maintenance of the greenhouses and the Arlington Experimental Farm.

The development of agriculture in the arid and semiarid regions was one of the objects to receive increased attention. The allotment for the study of dry-land methods was increased to \$125,000, of which \$50,000 will be available for the purchase and equipment of an experimental farm in the northern section of the Great Plains area to demonstrate the adaptability of agricultural and horticultural crops to the semiarid region. The studies in connection with the utilization of lands reclaimed under the Reclamation Act and similar areas were also continued with an allotment of \$69,600, and specific authority was given the Bureau to conduct investigations in connection with western irrigation agriculture. Provision was also made

for the continuance of studies undertaken several years ago of the methods of clearing logged-off lands, the testing of powders in clearing them, and the utilization of the by-products, \$5,000 being granted for the work. To investigate potato breeding and sugar-beet seed production for irrigated lands, a special appropriation of \$10,000 was made.

Great interest was also evinced by Congress in those phases of the Department's work dealing with farm management, and there was evident approval of efforts to extend to the country as a whole practical demonstrations of improved methods of farming. The well-known work inaugurated by the late Dr. S. A. Knapp in the South was continued with an appropriation of \$332,960, and its scope was so broadened that in future the entire cooperative demonstration enterprises of the Bureau in the South may be conducted under its auspices. In addition, appropriations were made aggregating \$300,000 to "investigate and encourage the adoption of improved methods of farm management and farm practice and for farm demonstration work." This appropriation is under the administration of the Office of Farm Management of the Bureau, and will more than double the funds at its disposal. It is announced that a portion of this large increase will be utilized in the extension and development of the investigation work of the Office, which is now covering a wide range of activity. The act itself provides that \$10,000 may be used in the investigation and utilization of cacti and other dry-land plants as food for stock, and other projects already under way or contemplated include the collection of data pertaining to the cost of various farm operations, the carrying on of farm surveys, the relation of climate to various farm enterprises, the effect of various types of farming on the maintenance of soil fertility, etc.

In the main, however, opportunity will be afforded to extend the demonstration phases of the work and thereby to establish closer relations with the individual farmer than ever before. Already, as is generally known, the Office has a well-developed system of organization, in which a State or group of States constitutes an administrative unit or district, in charge of an expert familiar with its needs in a broad way. In many cases cooperation with the agricultural colleges and experiment stations, county organizations, boards of trade and other commercial bodies, and many other agencies has permitted of numerous smaller divisions. The county unit has been established in several instances and has been found especially effective because of the opportunity for personal acquaintance and close familiarity with local conditions. Obviously little more than a beginning toward so detailed an organization as this can be expected, even with the enlarged appropriation, but the extension which will be possible

is expected to be of much assistance to the localities which can be reached thereby.

The largest allotment to any one bureau was made, as usual, to the Forest Service, although its appropriations show a reduction from \$5,533,100 to \$5,343,045. A cut of \$100,000 was made in the allotment for permanent improvements, for which \$400,000 will be available; one of \$90,920 in that for statutory salaries and one of \$43,080 for supplies, together with smaller reductions for several lines of investigation. The bulk of its appropriation will, of course, be expended in the maintenance of the National Forests, but there will also be available \$20,180 for range studies, \$165,640 for reforestation work in National Forests and experiments relating thereto, \$83,728 for silvicultural and dendrological experiments, \$31,360 for miscellaneous forest investigations and the preparation and dissemination of results, and \$170,000 for investigations of methods for wood distillation and preservation, timber testing, and wood utilization for paper making and other purposes. Special attention is to be directed to studies of the availability for distillation purposes of Douglas fir and other northwestern species of fir and timber. The appropriation of \$150,000 for fighting forest fires and similar emergencies was continued unchanged.

The appropriation of the Bureau of Chemistry was enlarged to \$968,940, of which \$25,000 represents an increase in connection with the enforcement of the Federal Food and Drugs Act of 1906. An additional inspection laboratory is being installed at San Juan, P. R.

The Bureau of Soils received an increase of \$41,520, mainly for soil surveys and fertilizer investigations, making its total \$301,420. The soil-survey work received \$165,000, and a provision carried in the last act restricting to 10 per cent expenditures in any one State was omitted. The investigations of the sources of natural fertilizers, begun last year and carried on with special reference to potash, were continued, and the appropriation was doubled, making \$25,000 available for the purpose. Studies of the relation of soils to drainage and seepage waters were also authorized, with an appropriation of \$5,000.

Although the estimates of the Bureau of Entomology called for \$601,920 as during the previous year, its appropriations reached a total of \$672,340. Of this increase \$35,000 was provided for a campaign against the much dreaded Mediterranean fly, which is causing considerable damage in Hawaii and much uneasiness to horticultural interests on the Pacific coast. The remaining increases were for studies of insects affecting cereal and forage plants, including the alfalfa weevil, and of insects affecting truck crops, sugar beets, and stored grains, and other products. The campaign against the gipsy and brown-tail moths was continued, no change being made in its appropriation of \$284,840.

The Biological Survey will receive \$191,400 as compared with \$139,700 in 1912, its increases being mainly for the administration of the additional game preserves already mentioned. A special allotment of \$3,000 is made for the destruction of ground squirrels in the National Forests in California. The general appropriation for biological investigations and the mapping of life zones was reduced from \$20,000 to \$10,000.

The various activities of the Office of Experiment Stations were continued, and in several cases with slightly enlarged appropriations. The total is \$1,871,700, of which \$1,440,000 is allotted to the State experiment stations under the Hatch and Adams Acts. Of the remainder \$58,240 is for statutory salaries, \$38,400 (a net increase of \$2,500) for general expenses, and \$15,760 (an increase from \$10,000) for the agricultural education service. The Alaska, Hawaii, and Porto Rico stations will again receive \$30,000 each, and the Guam Station \$15,000.

The nutrition and drainage investigations each received small increases, the former being allotted \$16,000 and the latter \$100,000. For irrigation investigations \$98,300 was granted, and a special investigation was directed of the feasibility and economy of irrigation by the reservoir system in western Kansas and Oklahoma.

The Office of Public Roads will have at its disposal \$202,120, an apparent increase of \$41,400. This increase will permit of additional assistance in meeting the rapidly growing demand for advice upon road construction and maintenance, and especially for additional field experiments in road making, road materials, and related questions.

A small increase is provided for the Bureau of Statistics, which will receive \$240,680. The inquiries already mentioned as to marketing methods are included in the allotments of this Bureau.

The work of the remaining branches was continued much as at present, but with small increases in each case. The Office of the Secretary is given \$292,280, the Library, \$41,280; the Division of Accounts and Disbursements, \$104,620; and the Division of Publications, \$219,700; and the fund for contingent expenses is \$106,066.

In connection with the appropriations included in the act itself reference should also be made to the funds derived in other ways. Mention has already been made of the permanent appropriation of \$3,000,000 for the meat-inspection work and to the annual appropriation of \$2,000,000 for the purchase of lands under the Appalachian Forest Reserve Act. There are also available until expended an appropriation of \$200,000 for the protection from fire of forested watersheds of navigable streams, to be expended in cooperation with the States upon request, and a small appropriation for the feeding

of elk in Wyoming. The appropriation for the Department printing and binding is carried in the appropriation act for sundry civil expenses, the allotment for 1913 being \$475,000, an increase of \$5,000. The Post Office appropriation act contains an appropriation of \$500,000 for expenditure by the Secretary of Agriculture in cooperation with the Postmaster General in studies of the possibilities of increasing the efficiency of the rural free delivery of mail by improving the condition of the roads, and conditional upon the raising by the States or local communities of double the Federal allotment. There should also be added \$25,000, included in an act approved August 20, 1912, providing for the inspection of imported nursery stock, a number of small deficiency appropriations, and an emergency appropriation of \$5,000, which went into effect July 30, for work in exterminating the army worm which has been causing considerable devastation to crops in the Southern States.

Eliminating the deficiency appropriations and the indefinite appropriations for watershed protection and elk feeding, the grand total for the Department and the State experiment stations becomes \$22,656,496. This is a considerable sum, although it will probably represent less than one-quarter of 1 per cent of the value of the farm crops of the year. When it is recalled that large appropriations will also be available for agricultural education in the land-grant colleges under the Morrill and Nelson Acts, for the rural education work of the Bureau of Education, demonstration work in agriculture among the Indians, certain phases of the census work of direct agricultural interest, and the payment of the country's quota toward the support of the International Institute of Agriculture, the wide extent to which the principle of Federal assistance to agriculture is being carried into practice becomes apparent. The further fact that most of the lines of work are provided for solely by annual appropriations and yet are being steadily continued, and in many cases still further augmented, indicates an increasing recognition of the benefits accruing to the country as a whole from a consistent and uninterrupted fostering of its agricultural development.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Studies on malic acid.—I. The transformation of malic acid to sugar by the tissues of the maple (*Acer saccharinum*), W. R. BLOOR (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 4, pp. 534-539).—With a view to determining whether the tissues of the maple tree were capable of transforming malic acid into sugar, tests were made with neutral calcium malate obtained by twice recrystallizing "sugar sand" acid calcium malate obtained by precipitating half the calcium from the neutral malate by means of oxalic acid and recrystallizing the product, malic acid obtained by removal of all the calcium from the crude neutral malate by oxalic acid (this product contained a small amount of cane sugar as an impurity), and pure malic acid obtained by precipitation of all the calcium from the neutral calcium malate. As it was believed that the transformation would be greatest in those parts of the tree showing signs of life at the time of the sap flow, viz, the swelling buds and shoots, aqueous extracts of these parts were made and the malic acid preparations added. Blanks were also prepared containing no malic acid, some solutions of the tissues were exposed to sunlight for certain periods of time, others kept in darkness, and other lots of tissues extracted with water or boiled. The amount of acidity and sugar was determined in each case.

The results showed that with the shoot tissues mixed with malic acid or malates and exposed to sunlight a diminution of acidity and an increase in reducing substances took place. This was interpreted as a transformation of malic acid into sugar. "A less pronounced change of the same kind is produced in darkness at 35°. The active principle which produces the change is somewhat soluble in water, is destroyed by boiling, and is therefore probably of enzym nature. The tissue of maple buds similarly treated brings about a decrease of reducing substance and an increase of acidity in solutions of malic acid or its salts."

The chemical composition of the substances contained in the birch, G. GRASSER (*Collegium*, 1911, Nos. 484, pp. 393-402; 485, pp. 405-412; 486, pp. 413-420; 487, pp. 421-425; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 24, p. 1462).—The author treated the residue obtained from the alcoholic extraction of 2 kg. of leaves from the white birch (*Betula alba*) with cold alcohol, ethyl ether, and dilute caustic potash solution and sulphuric acid, purified the constituents by further treatment, and observed their solubility in various liquids, together with their behavior with various reagents.

"The fraction of the extract dissolved by ether contained a wax-like, dark green mass of a resinous character, soluble in petroleum ether, which was found to have the composition  $C_{39}H_{68}O_2(OH)COOH$ , and yielded substitution products with metallic salts of the type  $C_{39}H_{68}O_2(OH)COO.Cu.CO(OH)O_2H_{68}C_{39}$ . The ethyl ester and also the acid chlorid and amid were prepared from it. By oxidation with fuming nitric acid, butyric acid was produced.

"The research showed that the substances which can be isolated unchanged from the young leaves of the birch consist principally of a resin, besides tannins of the pyrocatechol group and indifferent coloring matters. The absence of betulin and other glucosids in the leaves shows that these are derivatives of the compounds found and occur in older parts of the plant and particularly in the bark. The dry distillation of the resin from the leaves yields an odorous oil similar to that obtained from the bark, which shows that it has already the specific character of the birch product, its odor being similar to that conferred on Russian leather by tanning with birch bark."

In regard to the occurrence of formyl and acetyl groups in lignin, W. E. CROSS and B. TOLLENS (*Jour. Landw.*, 59 (1911), No. 2, pp. 185-196; *abs. in Chem. Ztg.*, 36 (1912), No. 9, *Reperl.*, p. 37).—This material has been substantially noted from another source (E. S. R., 25, p. 803).

Plant coloring matters, O. A. OESTERLE (*Schwiz. Wchnschr. Chem. u. Pharm.*, 50 (1912), Nos. 9, pp. 121-130; 10, pp. 137-141).—A review of the chemistry of the vegetable coloring matters.

In regard to chlorophyll, K. KAUTZSCH (*Naturw. Rundschau*, 26 (1911), Nos. 20, pp. 249-252; 21, pp. 261-264).—This is a review of present knowledge in regard to the chemistry of chlorophyll.

Colloid chemistry of foods and condiments, H. BECHHOLD (*Chem. Ztg.*, 35 (1911), No. 151, pp. 1401-1403).—Numerous examples are cited to support the hypothesis that the foundation of the preparation and judgment of foodstuffs and condiments lies in colloid chemistry.

Yearly reports in regard to the progress made in the examination of foods and condiments, H. BECKURTS, H. FRIEDRICHS and H. EMDE (*Jahresber. Untersuch. Nahr. u. Genussmit.*, 19 (1909), pp. 210; 20 (1910), pp. 166).—These are the reports for the years 1909 and 1910.

Determination of ustillaginous spores in wheat bran, G. GRÖH (*Kisérlet. Közlem.*, 14 (1911), No. 4, pp. 569-580, figs. 2).—Two methods are described for determining ustillaginous or smut spores in wheat bran.

In the first method the spores are washed from the bran with water. The starch which is carried over is dissolved and the fluid centrifuged. The protein precipitate, which settles with the spores, is removed by dissolving it with dilute sulphuric acid, and the spores are counted in an aliquot with a counting chamber. On the basis that 1 gm. of a clean sample of spores with a water content of 12 per cent contains 882,000,000 spores, the results can be expressed in percentages by weight.

In the second method 10 gm. of the bran is shaken with some water in a 100 cc. flask, the mixture made up to a bulk of 100 cc. with water, and the whole transferred to a beaker glass. After mixing the fluid thoroughly with a spoon a drop is taken from the surface of the fluid with a glass rod and placed in a counting chamber 0.1 mm. deep and with 16 squares 0.25 mm. on a side. On multiplying the average spore content of one preparation by 0.01133 the spore content of the bran is obtained in percentage by weight.

Inspection of foreign cyanogenetic haricot beans imported into France, GAUTIER and BORDAS (*Ann. Falsif.*, 4 (1911), No. 31, pp. 285, 286; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 7, p. 1757).—Only beans obtained from Burma are allowed to enter France, and these only when their hydrocyanic acid content does not exceed 20 mg. per 100 gm. An ordinary external examination was not found to be sufficient to detect cyanogenetic varieties, and accordingly the authors recommend a microscopic examination and a chemical analysis for hydrocyanic acid content.

A new method for calculating water in canned tomatoes and the detection of added water to canned tomatoes, L. A. CONGDON (*Jour. Indus. and Engin.*

*Chem.*, 3 (1911), No. 10, pp. 744-747).—The acidity of 46 out of 58 samples of canned tomatoes fluctuated between 50 cc. and 70 cc. of decinormal sodium hydroxid for 100 cc. of juice, and with an average of 59.7 cc. The average specific gravity of the juice from these 46 cans, strained through a cheese cloth of 40 threads to the inch, was 1.0202 at room temperature. The amount of water in the entire 58 samples varied from 90.44 to 96.18 per cent, and of the 46 samples was 93.95 per cent.

On the basis of the above figures the author evolved methods for determining the water in canned tomatoes and the detection of added water. For ascertaining the former the acidity of 100 cc. of juice, expressed in cubic centimeters of decinormal sodium hydroxid solution, is obtained. This figure is divided by 0.1 plus the specific gravity of the juice strained through cheesecloth, and the result (which is termed the ratio) subtracted from the acidity figure. The remainder is then taken from 100. In other words, 100 per cent minus the acidity, minus the ratio, equals the percentage of water.

The excess of water or added water in canned tomatoes is found by subtracting from the percentage of water found 90.44 per cent (the average percentage of water in canned tomatoes of the proper acidity). The highest amount of water added was found to be a little over 5 per cent. The excess water in the tomatoes was due to the addition of brine, used by some factories for conserving the tomatoes previous to canning. The average amount of salt in canned tomatoes was 0.14 per cent.

The above formulas can not be employed for cold packed tomatoes.

**Osmotic activity in the egg of the common fowl.** A. D. GREENLEE (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 4, pp. 539-545).—As a result of examining White Leghorn eggs at various periods during storage, and at temperatures varying from 32 to 80° F., it was found that the decrease in moisture in the white of the egg was not entirely due to evaporation by the external atmosphere. A certain portion of this moisture seemed to be transferred to the yolk, and this may be explained by the simple process of osmosis.

"The yolk, which contains a very high percentage of solids, is surrounded by a membranous tissue called the vitellin membrane, which in turn is surrounded by the egg white, a liquid much more dilute than the yolk. By osmosis the water passes through the membrane from the more dilute to the more concentrated solution until an equilibrium is obtained. In the egg this process continues until the vitellin membrane becomes so weak that it breaks, when the white and yolk begin to lose their identity. This action proceeds with such definiteness that by a process of calculation, knowing the original weight of the egg, the loss in moisture to the external atmosphere can be calculated with surprising closeness to the actual loss as shown by the balance."

As the change in water content increases its rate with the temperature, and diminishes with the time, it is possible by means of a rate formula which is given to predict the condition of the eggs at any temperature and at a given time within a reasonable storage period. Therefore, "the rate multiplied by the time gives the loss in weight, from which data it is a simple matter to find the percentage of moisture remaining."

The value of the guaiac tincture test for differentiating raw from boiled milk, RIEVEL (*Deut. Tierärztl. Wchnschr.*, 20 (1912), No. 11, pp. 161, 162; *Molk. Ztg. Berlin*, 22 (1912), No. 13, pp. 146, 147).—Tewes' statements (*E. S. R.*, 27, p. 13) in regard to the reliability of this test are not deemed valid under ordinary conditions. The chief reason for obtaining a positive reaction with some milks is that they have not been properly pasteurized or boiled.

**Better cream through grading.**—A new butter moisture test, G. H. BENKENDORF (*Wisconsin Sta. Bul.* 220, pp. 14, figs. 2).—In this bulletin the advantages

to be gained by grading cream are pointed out, and the establishment of 2 grades is recommended. The method of determining the acidity of cream by the use of alkaline tablets which is employed at the station is described.

"A new moisture test for butter [is also described, which] requires only 5 minutes for heating the butter, and is as accurate for practical purposes as the test made by the Wisconsin high pressure steam oven. The apparatus is a cast-iron oven  $3\frac{1}{2}$  by  $3\frac{1}{2}$  by  $1\frac{1}{4}$  in., with walls  $\frac{1}{8}$  in. thick set on a closed stand high enough to admit an alcohol lamp. The bottom of the sample dish is protected from excessive heat by a sheet of asbestos, while the conductivity of the iron supplies top heat to the sample and prevents foaming and spattering." Practical suggestions for using the test are given.

**The determination of moisture in butter, A. C. D. RIVETT** (*Chem. News*, 104 (1911), No. 2714, pp. 261-263, fig. 1).—An accurate method of determining the amount of moisture in butter is described, which depends on the action of water upon calcium carbide (E. S. R., 25, p. 410). Instead of measuring the acetylene evolved during the process the amount was found by determining the difference in weight before and after evolution. The apparatus used for the test is described and illustrated.

On comparing the results with those obtained by the ordinary heating method a difference of from 0.2 to 0.3 per cent was noted with butters having a moisture content of more than 12 per cent. These differences are probably due to the loss of volatile matter other than water brought about by direct heating.

**The refraction of the nonvolatile acids of butter, A. VAN RAALTE and F. A. J. LICHTENBELT** (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 3, pp. 81-98).—The purpose of this work was to determine the value of estimating the refraction of the nonvolatile acids of butter as an index for detecting adulteration. The authors conclude that in general the refraction of the nonvolatile acids of butter will give very little clue in determining whether a butter is pure or adulterated, very little more, in fact, than is obtained from the refraction of the butter fat itself or the Reichert-Meißl number.

**A modified butyrometer for determining the fat content of cheese, H. VAN GULIK** (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 23 (1912), No. 3, pp. 99-101, fig. 1).—This is a Gerber butyrometer so modified that it can be employed for determining the amount of fat in cheese.

In regard to the use of reversed filtration and the Weender methods for determining crude fiber, **J. SCHRÖDER** (*Jour. Landw.*, 58 (1911), No. 2, pp. 105, 106).—A polemic, in which the author points out that he has used the method of reversed filtration in conjunction with the Weender method for determining crude fiber for many years. He states that with the method a chemist can make from 12 to 16 single determinations of crude fiber within 8 hours.

**A micro-chemical test for digestible cellulose in feces, J. AMANN** (*Schweiz. Wehnschr. Chem. u. Pharm.*, 49 (1911), No. 48, pp. 697-700; *obs. in Chem. Abs.*, 6 (1912), No. 7, p. 875).—According to the author neither the Schmidt and Strasburger nor the Simon and Lohrlich methods, nor the direct microscopic examination of feces, will determine whether or not the residual cellulose present therein is digestible. For this purpose he proposes a micro-chemical reagent which is composed of 10 gm. of anhydrous zinc chloride, 2.5 gm. of potassium iodide, 0.25 gm. of iodine, and 10 gm. of distilled water.

"To apply the test, a small particle of fecal matter, or better, some of the sediment obtained by centrifuging a suspension of comminuted fecal matter in water, is put on a slide, a drop of the reagent cautiously added and the object at once examined under the microscope. Lignified or surface-hardened cell walls and other debris of indigestible cellulose are colored yellow or brown; merely thickened cell walls remain uncolored, but digestible cellulose is stained a char-

acteristic violet leaning more or less toward blue. This is seen, e. g., in the fecal débris of cellulose from bread or boiled potatoes. Simon and Lohrisch state that bread contains 0.2 to 0.4 per cent, potatoes 1.4 to 1.5 per cent of cellulose. Since starch and amylobacteria are turned more or less dark blue by this reagent, the latter detects and characterizes the 4 principles mentioned when they occur together. The observation should be made immediately, because upon prolonged contact with the reagent, thickened cellulose will also exhibit violet coloration."

**The canning of foods, A. W. BITTING** (*U. S. Dept. Agr., Bur. Chem. Bul. 151, pp. 77*).—This is a description of the methods followed in commercial canning enterprises. The object of the bulletin is to present in a popular form the methods in use in the better types of canning factories, to give teachers of home economics a more accurate idea as to this line of work, and to point out to the consumer what he may reasonably expect when purchasing canned goods, and finally what goes into canned goods. It deals with the early history and theories of preservation by canning; sterilization; modern factory equipment and methods; and detailed consideration of the various products, including fruits, vegetables, marine products, milk, and various specialties and soups.

**Peach drying in Chile** (*Bul. Mens. Off. Renseign. Agr. [Paris], 10 (1911), No. 6, pp. 707-710; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 7, pp. 1748, 1749*).—"The fruit-drying industry is widespread in Chile, especially in the province of Coquimbo, chiefly in the departments of Elqui and Ovalle, where the hot, dry climate and the high elevation promote rapid evaporation and make natural drying possible. There are two qualities of dried peaches. Those which are peeled and stoned before drying (*descarozados*), and those which are peeled and dried with the stones inside (*huesillos*)."

All varieties grown in Chile have adhering stones. Although the trees as a rule are not properly cared for, the average yield of irrigated, but not pruned, trees is about 220 lbs. of fruit per tree, varying from 110 to 660 lbs. The peaches are gathered before ripening, peeled by hand, sulphured, and exposed to the sun, wind, and dew for 3 days on wicker frames. After this the stones are removed with a short triangular-bladed knife (the smaller peaches are dried with the stone), and again placed on the wicker frames for a period of 3 days. This completes the process. Twenty-two lbs. of fresh peaches yield 4.4 lbs. of peels, 2.2 lbs. of stones, and 4.4 lbs. of dried fruit.

**[Converting low-grade vinegar into good vinegar]**, W. G. SACKETT (*Colorado Sta. Rpt. 1911, p. 21*).—This is a report of progress on a method by which low-grade vinegar (1 per cent acetic acid) can be converted into good vinegar conforming to the legal standard of 4 per cent acetic acid. This is accomplished by introducing a pure culture of yeast along with a culture of acetic acid bacteria, and by adding a 2 per cent cane-sugar solution to the low-grade product. In the experiments a product was obtained within 2 months which showed 5.7 per cent of acetic acid.

**Bacteria interfering with the malting process**, H. T. GÜSSOW (*Canada Expt. Farms Rpts. 1911, pp. 241-244*).—A description is given of a barley infected with *Bacterium herbicola rubrum* which was obtained from a virgin prairie field. On malting the barley the organism manifested itself by forming a pinkish growth which attacked the radicles and permeated the endosperm. On washing the grain with lime water before malting, no further trouble was experienced.

**The oil industry in Algiers**, J. FOUSSAT (*Gouv. Gén. Algérie, Dir. Agr., Inform. Agr. Bul. 12, 1912, pp. 132, pls. 7, figs. 44*).—This is a discussion of the economic situation, and the technology involved in the olive oil industry. It

also contains a short description of the methods for utilizing the by-products of the olive, the preparation of olive conserves, some chemical methods for examining olive oil, and plans illustrating the various types of oil factories.

The antiseptic effect of creosote oil and other oils used for preserving timber, J. M. WEISS (*Jour. Soc. Chem. Indus.*, 30 (1911), No. 23, pp. 1348-1353).—This work was done with pure cultures of *Bacillus subtilis*, *Saccharomyces glutinis*, and a species of *Penicillium* closely resembling the species described in Bulletin 118 of the Bureau of Animal Industry of this Department (E. S. R., 22, p. 531).

*S. glutinis* developed slowly on sterile wood, but after a few months showed its characteristic red color on the surface, and a microscopic examination of a thin section of the surface wood showed evidences of destructive action. The same was noticed with the bacillus, but neither seems to have a high degree of virility. The important feature seems to be that they make sound wood more susceptible to the attacks of higher fungi by a preliminary comparatively slight decomposition. The [*Penicillium*] grows very quickly on wood, and after 2 months the wood shows distinct signs of decay microscopically."

The materials investigated as regards the preservative action for wood were creosote oil with the bases, acids, and solid hydrocarbons removed, various materials added, water-gas tar distillates, pure phenol, cresol, naphthalene, anthracene, quinolin, and paraffin, and commercial creosoting oils. The results obtained are briefly summarized as follows:

"The neutral oils of creosote are strong antiseptics. The middle portion of these neutral oils from 235 to 270° is the strongest, the higher boiling oils are considerably weaker, the lower oils slightly so. High boiling bases of coal tar are strong antiseptics. The coal-tar acids are very strong antiseptics, their efficiency rising with the boiling point. The solid hydrocarbons, naphthalene and anthracene, have low antiseptic value. The addition of filtered tar in moderate amounts to creosote does not materially reduce its antiseptic value. Paraffin has no antiseptic qualities. Water-gas tar distillates have lower antiseptic value, and in this respect are decidedly inferior to the neutral coal-tar oils. Coal-tar creosote is in the highest degree superior as an antiseptic preservative to the water-gas tar distillates and petroleum residues, used for the same purpose."

Maize straw; its use for the manufacture of paper and fodder, B. DORNER (*English Patent* 8638, April 7, 1911; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 23, p. 1376).—"Maize stems are freed from dirt by treatment in a beating and dusting machine: they are then cut up, steeped in water, and shredded into fibers by special tubular refiners. The shredded material is boiled with a dilute solution of acetic acid (0.2 to 0.4 per cent) under a pressure not exceeding 3.8 atmospheres, the digesters being arranged in series so that the liquid from one may be used in the next on the counter-current principle. In this way 17 to 18 per cent of the straw can be extracted. The material is next boiled with lime-water, and, as this becomes neutralized, further small additions of alkaline liquid are made, e. g., milk of lime, a 0.2 per cent solution of sodium carbonate, or 0.1 per cent solution of sodium hydroxid. The end of the operation is indicated when neutralization of the alkali becomes slow. The acid and the alkaline extracts of the stems are evaporated separately to a sirupy consistency, then mixed and absorbed by finely ground maize stems to form a fodder. The extracted material is converted into paper pulp by digestion with sodium hydroxid, the pith cells being separated by treatment on sieves."

The sugar content of maize stalks, G. N. BLACKSHAW (*So. African Jour. Sci.*, 8 (1912), No. 8, pp. 269-273).—This article gives the results of an investigation of the Stewart method, which, briefly stated, consists of removing the

cobs from the corn stalk in the milk stage instead of allowing them to mature their grain. The object of doing this is to increase the saccharose content of the stalk until it practically becomes a sugar cane. Coincident with this, as a secondary result, it is claimed that there is very little deposition of the hard siliceous matter which forms the outer coating of the maize stalk and becomes incorporated with the peripheral fibers when the grain is allowed to ripen, thereby preventing the best of the fibrous matter from being utilized for the manufacture of pulp. In consequence of this, the whole substance of the stalk is resolvable into pulp, and cellulose of the finest quality for paper and for all the higher uses for which cotton cellulose is now employed may be obtained.

The author found, however, that "the sugar content of the cobbed and the uncobbed plants examined was practically the same; in other words, that the removal of the cob in the milky stage had no material influence upon the sugar content of the stalk."

See also previous note by Doby (E. S. R., 24, p. 707).

**The microscopy of certain paper pulps.** T. F. HANAUSEK (*Papier Fabrik.*, 9 (1911), No. 48, pp. 1464, 1465, figs. 2; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 24, p. 1446).—This is a description of the microscopical characteristics of paper pulps made from giant spear grass, which grows in the Terai district of India, and Kaing grass, which has its habitat in the Indian monsoon region.

**The microscopy of paper made from cane bagasse.** T. F. HANAUSEK (*Papier Fabrik.*, 9 (1911), *Sonderausgabe*, pp. 25-38, figs. 5; *abs. in Internat. Sugar Jour.*, 14 (1912), No. 157, pp. 55, 56, fig. 1).—A study of the microscopic characteristics of paper made from cane bagasse. The article is illustrated.

## METEOROLOGY—WATER.

**Meteorology.** W. I. MILHAM (*New York*, 1912, pp. XVI+549, pls. 14, figs. 143, charts 34).—This is essentially a text-book embodying a revision of the junior and senior elective course in meteorology delivered at Williams College during the past 8 years. "The book is also intended for the general reader of scientific tastes." Each chapter begins with a syllabus and ends with a list of references. A bibliography is given in an appendix.

The book "can hardly be called an elementary treatise, but it starts at the beginning and no previous knowledge of meteorology itself is anywhere assumed. It is assumed, however, that the reader is familiar with the great general facts of science." No attempt is made to discuss mathematical meteorology, meteorology applied to living things, meteorology and medicine, and the history of meteorology.

**On the estimation of humidity in agricultural meteorology.** M. NERUCEV (*Khozŭistvo*, 7 (1912), No. 4, pp. 89-95; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 862, 863).—Eleven years' observations on the relation of rainfall and yields of spring wheat gave inconclusive results, indicating the impossibility of drawing absolute conclusions from observations on a single factor. An important but often neglected factor is "the evaporating power of the soil and of plants, which is often two or three times as great as the atmospheric precipitation. . . . It is clear, therefore, how this factor must be regarded in calculating the balance of moisture in the soil available for plants. Zebediev has been led by his investigations to the opinion that the aqueous vapors which condense on the ground are of much importance, as they increase the reserve of subsoil water. Consequently, in studying the action of moisture on plant life, it is necessary to examine the conditions which, by accelerating or retarding the processes of condensation, determine the cir-

culation of aqueous vapor from the soil to the surrounding atmosphere, and again from the latter to the soil."

**Bulletin of the Mount Weather Observatory** (*U. S. Dept. Agr., Bul. Mount Weather Observ., 4* (1912), *pls. 4, pp. 183-304, figs. 38; 5, pp. 305-395, figs. 24; 6, pp. 397-456, figs. 13*).—These numbers contain the following articles:

*Part 4.*—Free Air Data: Sounding Balloon Ascensions at Indianapolis, Omaha, and Huron, by W. R. Blair.

*Part 5.*—Vertical Temperature Gradients in Hawaii, by A. J. Henry; Diurnal Variation of Pressure at Point Reyes Light, by J. Jones; The Temperature at Mount Weather and Adjacent Valley Stations (illus.), by A. J. Henry; and Free Air Data at Mount Weather for July, August, and September, 1911 (illus.), by W. R. Blair.

*Part 6.*—Dust Layers in the Atmosphere and Changes in the Neutral Points of Sky Polarization, by W. J. Humphreys; The Upper Atmosphere (illus.), by W. J. Humphreys; Echelon Clouds (illus.), by W. J. Humphreys; Review of Busch and Jensen "On the Facts and Theories of Atmospheric Polarization," by H. H. Kimball; and Free Air Data at Mount Weather for October, November, and December, 1911 (illus.), by W. R. Blair.

**Monthly Weather Review** (*Mo. Weather Rev., 40* (1912), *Nos. 1, pp. 1-162, pls. 10, figs. 3; 2, pp. 163-320, pls. 10, figs. 2*).—In addition to the usual climatological summaries, weather forecasts and warnings for January and February, 1912, notes on the application of upper-air observations to weather forecasting, January and February, 1912, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology, condensed climatological summaries, and climatological tables and charts, these numbers contain the following special papers:

*No. 1.*—Hydroelectric Development at Tallulah Falls, Ga., by C. F. von Herrmann; Climatic Charts of Savannah, Ga. (illus.), by J. deB. Kops; Winter Damage to Peaches, by J. W. Smith; The Climate of the City and Country Compared, by J. W. Smith; Notes on the Rivers of the Sacramento and San Joaquin Watersheds for January, 1912, by N. R. Taylor; A Study of Dry Seasons in San Diego, by F. A. Carpenter; Studies in Frost Protection—Effect of Mixing the Air (illus.), by A. G. McAdie; and Report on the January, 1912, Freshet in the Willamette River, by E. A. Beals.

*No. 2.*—Storm of February 22, 1912, at New York City, by C. D. Reed; The Average Stream Flow of the Coosa and Alabama Rivers, by C. F. von Herrmann; Smudging Against Frost; Storm of February 20, 1912, at Austin, Tex., by A. Deussen; The Cooperative Weather Bureau Observers of Utah, by J. C. Alter; Notes on the Rivers of the Sacramento and San Joaquin Watersheds during February, 1912, by N. R. Taylor; Weather at Fresno, Cal., during February, 1912, by W. E. Bonnett; Note on the Weather at Point Reyes Light, Cal., during February, 1912, by J. Jones; Effect of Abnormal Weather Conditions during the Construction of the Los Angeles Aqueduct, Abstracted from Report of the Engineers, by A. G. McAdie; and Covering Almond Trees for Frost Protection (illus.), by A. G. McAdie (see p. 345).

The weather of the past agricultural year, F. J. BRODIE (*Jour. Roy. Agr. Soc. England, 72* (1911), *pp. 418-424*).—The weather conditions for the British Isles during 1911 are summarized in the usual form and compared with the averages for previous years. The main characteristics of the weather of the year were a deficiency of rainfall and excess of temperature and sunshine.

The weather of Scotland in 1911, A. WATT (*Trans. Highland and Agr. Soc. Scotland, 5, ser., 24* (1912), *pp. 337-349*).—This report, like those of previous years, "consists of (1) a general description of the weather over the Scottish area from month to month; (2) a selection of rainfall returns, in which each

county in Scotland is represented by one or more stations. . . . The outstanding features of the year were the high level at which the barometer stood for long periods during the first 10 months, the large amount of mild or warm weather experienced, and the remarkable rainfall shortage in some eastern districts."

**The chemistry of rare rain** (*Lancet [London]*, 1912, I, No. 19, p. 1291).—Examinations of rain which fell in London after a 5 weeks' drought, the sample being taken about 1 hour after the rain began to fall, showed 0.525 gr. of ammonia per gallon of water. This is about seven times more than is found in rain collected under normal conditions.

**The fertilizing value of rain and snow**, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1911, pp. 200, 201).—This is a report on the fourth year's work on this subject (E. S. R., 24, p. 417), covering the year ended February 28, 1911. The precipitation during this year was 26.97 in., about 10 in. below the average for the locality. The total nitrogen per acre brought down by rain and snow was 5.27 lbs., about 84 per cent being furnished by the rain and 16 per cent by snow. Of the total nitrogen, 3.73 lbs. was in the form of free and albuminoid ammonia and 1.54 lbs. as nitrates and nitrites.

**Observations on the ground water level**, F. VOGEL (*Mitt. Dcut. Landw. Gesell.*, 27 (1912), No. 23, pp. 328-330, figs. 4).—The importance from the standpoint of water supply, drainage, etc., of systematic observations on the level of the ground water by means of tubes put down in the soil, and methods of making and interpreting such observations, are briefly discussed.

**Report of progress of stream measurements for the calendar year 1910**, P. M. SAUNDER (*Dept. Int. Canada, Sess. Paper No. 25d*, 1912, pp. 244, pls. 16).—Descriptions of the stream and creek basins are given, the methods of procedure outlined, and a large amount of tabulated data and stream measurements are given.

**The water supply of farm homesteads**, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1911, pp. 201-206).—Analyses of 130 samples of water are reported, of which 43 were considered wholesome, 36 suspicious, 33 seriously contaminated, and 18 saline.

**Sterilization of drinking water by ultraviolet light**, J. COURMONT (*Chem. Ztg.*, 35 (1911), No. 87, p. 806; *abs. in Jour. Soc. Chem. Indus.*, 30 (1911), No. 16, p. 1027; *Chem. Abs.*, 6 (1912), No. 9, pp. 1190, 1191).—"The author discusses the remarkable sterilizing power of the ultraviolet light from a quartz mercury vapor lamp. For sterilizing water, which is comparatively transparent to the radiation, it is sufficient to place the lamp in the axis of a cylindrical vessel 60 cm. in diameter. Liquids containing colloids (wine, beer, peptone solution, etc.) absorb the ultraviolet rays rapidly, and therefore sterilization is limited to the surface layer. It is therefore necessary that for greatest efficiency the water to be sterilized must be as clear as possible. The action of sterilization is in no way connected with ozone or hydrogen peroxid formation."

**Purification of water by Infusoria**, C. S. STOKVIS and N. H. SWELLENGREBEL (*Jour. Hyg. [Cambridge]*, 11 (1911), No. 4, pp. 481-486; *abs. in Chem. Abs.*, 6 (1912), No. 9, p. 1191).—The investigations here briefly reported are summarized as follows:

"Infusoria have the same bactericidal power as flagellates. Emulsions containing *Bacillus typhosus*, *Vibrio cholera*, *V. Dunbar*, *V. El Tor*, *B. megatherium*, and *Spirillum volutans*, to which *Colpoda cucullus* is added, are soon cleared. Before the clearance the Colpoda multiply actively.

"This bactericidal effect does not depend upon the production of toxic substances by the Infusoria. The fluid obtained from filtered cultures of the

Infusoria exerts no bactericidal effect. Only living Colpodæ are able to clear the emulsions.

"Direct sunlight does not prevent the clearing of the emulsions by the Infusoria, but temperatures below 10° C. and above 30° C. and absence of oxygen (anaerobic culture) are unfavorable to their exerting a bactericidal effect.

"The polluted water of the canals of Amsterdam slightly delayed the clearance of the emulsions; the sewage of starch factories and gas factories completely prevented this clearance.

"Consequently under natural conditions Infusoria will only play a part in purifying river water (1) if the temperature is above 10° and under 30° C., (2) if the aquatic vegetation is rich enough to supply the necessary quantity of oxygen, (3) if the water is not highly polluted by adjoining factories."

Sewage pollution of interstate and international waters with special reference to the spread of typhoid fever, A. J. McLAUGHLIN (*Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab. Bul. 83, 1912, pp. 296, charts 91, maps. 39*).—This report deals with Lake Superior and St. Marys River; Lake Michigan and the Straits of Mackinac; Lake Huron, St. Lawrence River, Lake St. Clair, and the Detroit River; and Lake Ontario and St. Lawrence River. See also a previous report (*E. S. R., 25, p. 720*).

It is shown that "there is an undue prevalence of typhoid fever in many cities and towns in the drainage basin of the Great Lakes. This excessive prevalence of typhoid fever, especially in the winter and spring months, is due in greatest measure to sewage pollution of interstate and international waters used as a source of public water supplies. Given the sewage pollution of the source of supply, the excessive prevalence is made possible by the use of such water unfiltered and untreated or by the faulty operation or poor efficiency of filter plants. Most of the cities with excessive prevalence of typhoid fever use unfiltered surface water as a public supply, although disasters have occurred where inefficient filtration was being depended upon to make a polluted water safe."

The suggested remedy for the conditions described is, therefore, the substitution of carefully filtered or treated supplies "for the present polluted or dangerous public supplies where adequate protection of such supplies against pollution is not feasible." Specific advice is given on this point.

The Berlin sewage farms (43,009 acres), H. A. ROEHLING (*Jour. Roy. Sanit. Inst., 33 (1912), No. 5, pp. 178-206*).—This is a more detailed account of the work of these farms during the year ended March 31, 1910, than that previously noted (*E. S. R., 26, p. 317*). An important practical fact emphasized in the article is that in addition to efficiently purifying the sewage the farms paid a net profit of \$2.66 per million gallons of sewage handled.

Irrigation with sewage (*Engin. Rec., 65 (1912), No. 3, pp. 82, 83*).—A plea is made for better utilization of the fertilizing matter of sewage, and the general proposition is advanced that better results from an economic standpoint could be obtained by quick handling of fresh sewage in a large number of small plants rather than by one large plant involving more or less decomposition and loss of fertilizing matter in the sewage. In an editorial, commenting on this proposal, the practical difficulties in the way of utilization of sewage for fertilizing purposes are concisely stated.

The struggle with sewage sludge, W. NAYLOR (*Surveyor, 41 (1912), No. 1064, pp. 818-821, fig. 1*).—The article reports a number of analyses of sludge and discusses its value as fertilizer, more particularly certain recently proposed methods for preparing the sludge in improved form for this purpose.

The most important improvement brought about by these methods is the reducing of the sludge to a light friable material free from excessive water

and grease, especially the latter. Analyses by the author of several samples of sludge show grease varying from 2.2 to 20.7 per cent on the basis of dry matter; also phosphoric acid from 1 to 6.3 per cent, and nitrogen from 0.8 to 3.8 per cent. Various processes of removing the grease are described, preference being accorded to the so-called Ekenburg wet carbonizing process originally designed for wet distillation of peat.

### SOILS—FERTILIZERS.

**Soils of the eastern United States and their use, XXXVI—XXXVII, J. A. BONSTEEL** (*U. S. Dept. Agr., Bur. Soils Circs. 63, pp. 16; 64, pp. 12*).—These circulars discuss 2 soil types with respect to geographical distribution, characteristics, surface features and drainage, use, improvement, and crop adaptations.

Circular 63 discusses the Volusia silt loam, of which a total of 821,184 acres have been surveyed and mapped by the Bureau of Soils. It "is an extensive type of soil developed at the higher altitudes in the glaciated northern portion of the plateau country which extends westward along the New York and Pennsylvania line from the vicinity of the Delaware River to the northeastern part of Ohio." The surface drainage is fairly well established, but "the internal drainage of the subsoil is poor over considerable areas, and numerous springs give rise to small swampy areas even upon some of the steeper slopes. Tile drainage is one of the chief requisites to the better farming of large areas of this soil." Oats, buckwheat, potatoes, and grass for pasture and hay are the principal crops. Corn is grown successfully only at the lower elevations except for silage, in which case it may be grown at higher altitudes, the flint varieties being best adapted.

Circular 64 discusses the Hagerstown clay, of which a total of 371,290 acres in 12 different areas in 7 States have been surveyed and mapped. This type "is an extensive limestone valley soil occurring throughout the valleys of the Appalachian Mountain region and of the blue-grass region of Kentucky. The soil is particularly well suited to the production of wheat and grass, and upon properly tilled areas corn is also an important and profitable crop. The topography of the type is usually rolling and sloping and the natural surface drainage is good."

**The soils of Prince George's County, J. A. BONSTEEL** (*In The Physical Features of Prince George's County, Baltimore: Md. Geol. Survey, 1911, pp. 151-184*).—This report was prepared under the supervision of the Bureau of Soils of this Department and describes the agricultural conditions, geological relationships, and physical and chemical characteristics of the leading soil types of the county.

The entire area, excepting a small part covered by the Cecil mica loam, lies within the Coastal Plain region of the State. The most important soil types are the Leonardtown loam, Susquehanna gravel, Windsor sand, Westphalia sand, meadow, Norfolk sand, Collington sandy loam, Susquehanna clay, and the Susquehanna clay loam, all "derived from the unconsolidated sediments belonging to the mesozoic and cenozoic portions of the geological column."

"The great variety of soils found in the county, the moderate climate and general healthfulness of the greater part of the county, its accessibility by rail and by water, all favor a greater specialization of agriculture and increased profits from the cultivation of the soil."

**Has the fertility of land in India decreased? B. COVENTRY** (*Agr. Jour. India, 7 (1912), No. 1, pp. 45-54*).—This article gives in synopsis form the replies of the agricultural directors of the various provinces of India to the question as to the relative fertility of agricultural land at present as compared with former

times. It is concluded that although there is no statistical evidence to show what change has taken place the reports would indicate that the fertility of Indian soils has been more or less in a stationary condition with a tendency to improve under better treatment. The low rate of production in India as compared with western nations is attributed mainly to the small amount of capital employed.

Modern soil investigations, K. O. BJÖRLYKKE (*Tidsskr. Norske Landbr., 1912, No. 2, Sup., pp. 60*).—A lecture delivered in January, 1912, being a general discussion of soil problems, the methods of soil investigations adopted in Germany, Hungary, Bohemia, France, England, and the United States, and the history of soil studies in Norway. A chapter on simple practical methods of investigation of soils is included at the close of the pamphlet.

On the degree of consistency and stiffness in soils, A. ATTERBERG (*K. Landtbr. Akad. Handl. och Tidskr., 51 (1912), No. 2, pp. 93-123, figs. 21*).—The author's method of classifying soils according to their physical characteristics as regards plasticity and firmness is given. Two forms of apparatus for the determination of firmness and plasticity figures are described and the results obtained are discussed for purposes of soil classification. See also a previous note (*E. S. R., 26, p. 220*).

Corrections in physical science, D. L. NARAYANA RAO (*Hyderabad, Deccan, India, 1912, pt. 1, pp. 17; pt. 2, The Rationale of Agriculture, pp. 31*).—These pamphlets deal particularly with physical factors controlling soil moisture and the relation of tillage operations thereto. Attention is called to the fact that soils have in many cases been shown to lose much more water by evaporation and transpiration from plants than is supplied by precipitation, an apparent yearly deficit of about 25 in. from the earth's surface being generally admitted. The author maintains that the deficit is supplied and proper moisture conditions maintained in the soil not by capillary rise from below, for "there is no such thing as capillarity" as the term is generally understood, but by absorption of aqueous vapor from the air which penetrates and permeates the soil in a so-called process of "breathing."

"For the vapor to be properly caught or for allowing every individual soil grain to breathe well, the grains or particles must present to the air as much of their surfaces as possible at the same time touching each other gently on all sides. It is only then that perfect breathing of soils takes place. Where such breathing is going on in nature the soils are highly fertile and centuries of constant cultivation are unable to exhaust their fertility. I can quote as instances almost all the new formations by geological actions. They are most fertile. Nature is always digging and plowing and draining and making new soils. The breathing of the earth is the greatest geological force in nature."

The moisture content of packed and unpacked soils, F. T. SHUTT (*Canada Expt. Farms Rpts. 1911, p. 172*).—Further observations (*E. S. R., 24, p. 421*) on the effect of subsurface packing in conserving soil moisture showed no very great advantage from this practice, although it appeared that the packed land started the season with slightly more moisture than that which had not been so treated.

Soil tank investigations, A. W. BLAIR (*Florida Sta. Rpt. 1911, pp. XXXII-XXXIX, figs. 4*).—Experiments on the effect of different combinations of fertilizers on the growth and health of orange trees growing in tanks at the station (*E. S. R., 25, p. 427*) are reported, with measurements of rainfall, determinations of moisture in the tank soils, and analyses of the drainage from the tanks and of soils from a number of orange groves.

The experiments have not proceeded far enough to give conclusive results. It appears to be clearly indicated, however, that the soils of orange groves are

likely to lose nitrogen rapidly and hence to be deficient in this constituent. The tank soils lost nitrogen, mostly nitrates, in the drainage at the rate of 910½ lbs. of sodium nitrate per acre from July 7 to May 23. The surface soil of the orange groves examined contained only about one-half as much nitrogen as that of virgin hammocks. The loss of phosphoric acid and potash in the drainage of the tanks was much smaller than that of nitrogen, and there was less difference in this respect between virgin and the orange-grove soils.

**A study of alkali soils, E. F. LADD and ALMA K. JOHNSON** (*North Dakota Sta. Spcc. Bul., 2 (1912), No. 4, pp. 55-58*).—The results of determinations of alkali salts in soils upon which the oat crop showed marked difference in productivity are reported, and correlated with crop yields in pot experiments with oats, timothy, and alfalfa with and without additions of gypsum and blood to the soil.

From the results of the analyses it is estimated that the poor soils contained 173,550 lbs. of water-soluble alkali salts per acre to a depth of 2½ ft. as compared with 18,600 lbs. in the good soils. The sodium carbonate content, however, was lower in the poor soils. Applications of gypsum gave slightly increased yields with oats and timothy. Blood also acted very favorably with these crops. In view of the fact that the soils were already well supplied with nitrogen it is believed that the beneficial effect of the blood may have been due to the incorporation with the soil of nitrifying organisms. Alfalfa was not benefited by the addition of either gypsum or blood.

**Plant food lost in drainage from uncultivated peat soils and from such soils growing different crops, H. VON FEILITZEN ET AL.** (*Scenska Mosskulturför. Tidskr., 26 (1912), No. 2, pp. 111-154, figs. 4*).—The results of 5 years' lysimeter trials at the Jönköping Experiment Station are reported.

Eight cement boxes (15 by 80 cm., 50 cm. deep) were placed in the ground and connected with bottles for collection of drainage waters. Each lysimeter was filled with about 94.5 kg. (about 207.9 lbs.) of a good quality of peat soil, containing about 60 per cent organic matter, 0.78 per cent lime, 0.66 per cent potash, 0.13 per cent phosphoric acid soluble in 12 per cent cold hydrochloric acid, and 2.15 per cent nitrogen. Two of the lysimeters were left unfertilized, while applications of superphosphate, superphosphate and 37 per cent potash salts, or the latter fertilization with nitrate of soda, were made to two lysimeters each. The amounts of fertilizers applied each year are given and the crops grown during the years 1906 to 1909, viz. oats, potatoes, and ruta-bagas. During the first year the soil lay fallow in all lysimeters. Complete data are presented as to amounts of precipitation, drainage water, and plant food (lime, potash, phosphoric acid, and nitrogen) removed in the drainage water and in the crops during each year. Analyses of the soil in all lysimeters in three different depths were made at the conclusion of the trials. The results obtained are discussed in some detail.

During the first year (fallow) considerable lime, nearly as much potash, and considerable nitric nitrogen were washed out, while the loss of phosphoric acid was insignificant. The losses were most marked in the case of the fertilized soil. During the 4 years when crops were grown on the soil the losses of lime were likewise largest, with potash and nitrogen following in the order given; the losses of phosphoric acid were small and of no practical importance. Much larger losses were sustained for lime and nitrogen on the unfertilized than on the fertilized soil, owing to the smaller crops grown thereon, while the losses for potash were about the same in all cases. The losses on the grass plats were considerably smaller than for the other crops. The soil analyses showed that in spite of the fertilizer applied the contents of lime, potash, and nitrogen were diminished during the 5 years' experimental period, while that

of phosphoric acid increased. The decrease was, however, small in proportion to the total amounts of the ingredients in the soil.

Regarding humus acids of *Sphagnum* turf, S. ODÉN (*Ber. Deut. Chem. Gesell.*, 45 (1912), No. 4, pp. 651-660; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 7, p. 350; *Chem. Abs.*, 6 (1912), No. 16, pp. 2275, 2276).—The author first reviews briefly different conceptions regarding the nature of humus acids, particularly as regards the question whether the reaction between alkali and humus acid results in a peptonization of the colloidal material or in a chemical precipitation of noncolloidal alkali compounds. He then describes a method of preparing solutions of ammonium humate free from colloids and from it, by precipitation with hydrochloric acid, humic acid in suspension free from salts, and reports studies of the reaction changes between humic acid suspensions and alkali solutions as determined by conductivity measurements.

The results of such measurements show that the interactions between ammonia solutions and humus acid really resulted in salt formation. The neutralization of sodium hydroxid with humic acid gave an equivalent of the acid of about 339. It appeared that humic acid is probably tribasic with a molecular weight of about 1,000. Purified humic acid when dried at 100° C. was converted into a hard mass which formed a black, lustrous powder. This powder did not go into suspension in water and was not soluble in alkali solutions immediately, but when treatment (with sodium hydroxid) was prolonged it gradually passed into solution yielding a brown liquid.

The influence of carbon upon nitrification, H. W. CLARK and G. O. ADAMS (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 4, pp. 272-274).—Experiments are reported which showed that the addition of easily assimilable carbohydrates like sugar and molasses to sewage filter beds checked nitrification but at the same time tended to clear the beds of organic matter.

The present status of soil inoculation, K. F. KELLERMAN (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 1-3, pp. 42-50, pls. 2).—This is the full text of a paper of which an abstract has already been noted (*E. S. R.*, 26, p. 520). An annotated bibliography of American studies on the subject is appended to the article.

Azotogen, nitragin, and natural inoculating soil, A. KÜHN (*Centbl. Bakt. [etc.]*, 2. Abt., 30 (1911), No. 21-24, 548-552).—The author takes exception to the conclusions of von Feilitzen (*E. S. R.*, 25, p. 123) regarding the relative efficiency of azotogen and nitragin.

Azotogen, nitragin, or inoculating soil, E. TEISLER (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 1-3, pp. 50-56).—The relative merits of these materials for inoculating purposes are discussed on the basis of the work of von Feilitzen (*E. S. R.*, 25, p. 123), A. Kühn (see above), and others.

Inoculation experiments with nitragin for legumes, F. T. SHUTT (*Canada Expt. Farms Rpts. 1911*, pp. 174-176).—As in previous years, there was no material benefit from the use of this material.

Nitrogen enrichment of soils through the growth of clover, F. T. SHUTT (*Canada Expt. Farms Rpts. 1911*, p. 173).—Further observations on this subject (*E. S. R.*, 22, p. 321) showed that the soil continues to increase in nitrogen under this treatment.

The increasing of the ammonia fixing power of soils under the influence of calcium carbonate, O. LEMMERMANN and L. FRESSENIUS (*Fühling's Landw. Ztg.*, 61 (1912), Nos. 7, pp. 240-253, fig. 1; 8, pp. 274-285).—It was found, in these experiments that the addition of calcium carbonate to soil in pots to the extent of 1 per cent reduced the volatilization of ammonium carbonate and increased the absorptive power of the soil for ammonia. Caustic lime had the

opposite effect. Calcium sulphate and chlorid reduced loss solely by their direct action on the ammonium carbonate.

The chlorid was the only salt of magnesium which reduced loss of ammonia. Potassium and sodium chlorids, sulphates, and carbonates, as well as kainit and Thomas slag, reduced the absorptive power of the soil. Treatment with alcohol was without effect. On the other hand steaming, and especially igniting, had a marked effect.

The effect on absorption was dependent not only upon the bases but upon the nature of the acids with which they were combined. The absorptive power of the soil appears to be dependent mainly upon the exchange of bases in the zeolite compounds. The more rapid the aeration the greater was the loss of ammonia. The character of the soil exerts a great influence not only on the absorption of ammonia but on the action of lime on the absorption, rendering the addition of lime favorable, unfavorable, or without effect. See also previous notes (E. S. R., 21, p. 417; 26, p. 320).

The active potash of the soil and its relation to pot experiments, G. S. FRAPS (*Texas Sta. Bul.* 115, pp. 39, figs. 3).—The results of studies of the active potash in soils as measured by the solubility in fifth-normal nitric acid are reported, and the analytical data compared with crop yields in pot experiments with different crops on a large number of Texas soils. During the course of the work a study was made of the solubility of potash of a number of minerals which may be present in the soil. The method of conducting the pot experiments was substantially the same as that employed in studies of the active phosphoric acid (E. S. R., 23, p. 423). The author summarizes his results as follows:

“The potash of nephelite, leucite, glauconite, biotite is completely extracted by strong hydrochloric acid. About one-third of the potash of muscovite is extracted and only a small percentage of the potash of microcline and orthoclase. Practically no potash is removed from orthoclase and microcline by fifth-normal nitric acid, less than 10 per cent from glauconite and biotite, and from 15 to 60 per cent from muscovite, nephelite, leucite, apophyllite, and phillipsite.

“Potash dissolved by fifth-normal nitric acid from soils represents a portion of the potash in the easily decomposed minerals. From 36 to 100 per cent of the potash absorbed from aqueous solution by certain minerals was extracted by fifth-normal nitric acid. Two per cent ammonia dissolved from 9 to 45 per cent of the potash absorbed by minerals.

“The potash extracted represents the difference between the potash dissolved and that fixed from the solution. The fixation of potash from fifth-normal nitric acid is much less than the fixation of phosphoric acid from the same solvent. The potash extracted from the soil by successive treatments with fifth-normal nitric acid at first represents easily soluble potash, and is finally reduced to the small amount of potash dissolved from highly insoluble minerals. Increasing the quantity of potash mineral to a fixed amount of solvent increases the quantity of potash extracted, but the percentage of the potash extracted decreases.

“The quantity of potash extracted by fifth-normal nitric acid below 50 parts per million represents 1 to 2 per cent of the potash of highly insoluble silicates. The quantity extracted in excess of approximately 50 parts per million represents a comparatively large percentage of a much smaller quantity of more easily soluble potash.

“The potash extracted by fifth-normal nitric acid from the soil is not necessarily in the same form of combination in different soils and does not necessarily have the same value to plants. . . .

"The percentage of crops which show an increase in growth caused by the addition of potassium fertilizers, decreases from 86.7 with soils containing less than 50 parts per million of active potash to zero in soils containing 800 to 1,000 parts per million of active potash. The effect of the potash decreases with the active potash in the soil.

"The percentage of crops injured by the potash increases with the quantity of active potash in the soil.

"The effect of the addition of potash to the soil upon the average weight of the crop in the pot experiments decreases with the quantity of the active potash in the soil. When the soil contains more than 200 parts per million of active potash, addition of potash does not increase the average weight of the crop, but often decreases the crop.

"The average percentage of potash contained in 235 crops increased with the percentage of active potash in the soil. The average quantity of potash removed from the soil by the crops increases with the quantity of active potash in the soil. Relatively enormous quantities of potash are removed by the crops in these pot experiments. Expressed in terms of bushels of corn equivalent to the potash removed, the quantity averaged 58.6 bu. in soils containing less than 50 parts per million of active potash and 413.8 bu. in soils containing 600 to 800 parts per million.

"Deficiency of plant food is a relative term and depends upon the growth which can be made under the conditions of the experiment. Soils containing less than 50 parts per million of active potash were deficient in 87 per cent of the pot tests and the average crop without potash is 67 per cent of that with potash, and yet these soils gave up enough potash to the crop to produce 58 bu. corn to the acre, on the average.

"There is a loss of active potash consequent upon the cropping of the soil. The loss is approximately one-half of the potash taken up by the plant when the active potash exceeds 100 parts per million. When the active potash is between 50 to 100 parts per million, the loss is about one-fifth of the potash taken up by the plant. When the active potash is about 50 parts per million or less, there may be no observed loss."

The feeding of plants with mineral matter through the leaves, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 10 (1912). No. 1, pp. 6, 7, fig. 1; Deut. Obstbau Ztg., 1912, No. 7, pp. 143, 144, fig. 1*).—A brief account is given of the growing of rape plants in sterile sand practically free from potash, certain of the plants receiving no application of potash while in other cases a 2 per cent solution of potassium sulphate was painted upon the leaves from time to time but no potash was applied to the soil. The plants grown in sterile sand without potash made practically no growth while those on which the potash solution was applied to the leaves grew and matured normally.

Results of cooperative fertilizer tests on clay and loam soils, J. B. ABBOTT and S. D. CONNER (*Indiana Sta. Bul. 155, pp. 99-132, figs. 7*).—During the past 8 years about 225 cooperative fertilizer tests on clay and loam soils have been undertaken by the station, mainly with corn and wheat, but also including oats, potatoes, cannery tomatoes, and one or more experiments with each of 15 other crops of less general importance. Such of the results of the corn, wheat, oats, potato, and tomato experiments as are deemed of value, one timothy experiment, and a few miscellaneous experiments, are included in this bulletin.

The results of these experiments are summarized as follows:

"In the corn fertilization experiments, complete fertilizer gave the largest average increase, but phosphoric acid and potash gave the largest average profit. In the amounts used on corn, nitrogen caused a small average increase and was used at a loss, potash caused a larger average increase and was used

at a profit, and phosphoric acid caused the largest average increase and was used at the greatest average profit per acre.

"In the wheat fertilization experiments the complete fertilizer gave the largest average increase, and the greatest average profit per acre. In the amounts used on wheat, each element was profitable, and they stood in the same order of importance as in the corn fertilization experiments. The use of 200 lbs. of fertilizer per acre on wheat proved more profitable than the use of 100 lbs. per acre.

"Phosphoric acid and potash gave a greater profit, per dollar invested in fertilizer, than complete fertilizer, on both corn and wheat. Fertilizer gave a greater average profit per acre on wheat than on corn, and was profitable in a much larger percentage of the experiments.

"Fertilization increased the yield of oats about the same number of bushels per acre as in the case of wheat.

"In the potato fertilization experiments, complete fertilizer gave the greatest average increase, but the amount used was apparently too large to give the greatest immediate profit. The formula used for potato fertilization, 4:8:10, was found to be relatively too low in phosphoric acid content in proportion to nitrogen and potash. In the amounts used for potato fertilization, nitrate of soda was not as effective as dried blood. Muriate and sulphate of potash were equally effective in increasing the yield, but in some cases sulphate produced potatoes of better quality.

"In the tomato fertilization experiments, complete fertilizer gave the largest average increase and the largest average profit. It was more profitable to use 500 lbs. of fertilizer per acre on tomatoes than to use 250 lbs. per acre. Nitrogen derived partly from nitrate of soda and partly from dried blood gave better results on tomatoes than nitrogen derived wholly from dried blood, or wholly from nitrate of soda. Fertilization of tomatoes in the hill gave better results than broadcast fertilization.

"The use of complete fertilizer gave better results on timothy than the use of nitrate of soda alone, particularly the second year.

"Nitrogen derived from peat was not as effective as nitrogen derived from dried blood in any case. The purchase of nitrogen in large amounts for corn and wheat fertilization did not prove profitable.

"Heavy applications of fertilizer showed a lasting effect comparable to that of manure. Rock phosphate did not give appreciable results until the second year after application.

"In nearly all experiments with all crops on clay and loam soils phosphoric acid was found to be the most effective of the fertilizer elements."

The fixation of atmospheric nitrogen by the use of aluminum nitrid, F. MARRE (*Génie Civil*, 61 (1912), No. 2, pp. 30-33; *Engrais*, 27 (1912), No. 21, pp. 577-581; *abs. in Chem. Abs.*, 6 (1912), No. 15, p. 2130).—The history, theory, and the practical operation of this method of fixation of free nitrogen are discussed. The process is of special agricultural importance because of the high nitrogen content (33 to 35 per cent) and cheapness of production of the nitrid. Its direct action as a fertilizer has, however, not been fully investigated.

On phosphoric acid fertilization and its importance in moor culture, H. VON FEILITZEN (*Svenska Mosskulturför. Tidskr.*, 26 (1912), No. 2, Sup., pp. 64, figs. 30).—A treatise on the subject, based largely on the results of recent investigations and practical experiences in the cultivation of moor soils. The results show the predominant need of phosphatic fertilizers on these soils.

The fertilizing value of superphosphate, F. KLINKERFUES (*Zentbl. Kunstdünger Indus.*, 16 (1911), p. 376; *abs. in Chem. Ztg.*, 36 (1912), No. 4, Repert., p. 19).—The changes which phosphate undergoes in the process of treatment

with acid and during the "ripening" (and reversion) of the superphosphate on standing are discussed in relation to the availability of the phosphoric acid to plants. It is claimed that the "ripened" superphosphate is readily available and is less subject to leaching in the soil.

The use of phosphatic fertilizers in France, HITIER (*Bul. Soc. Encour. Indus. Nat. [Paris]*, 115 (1911), No. 6, pp. 848-855; *abs. in Nature [London]*, 88 (1912), No. 2204, p. 429).—The amount and character of phosphates used in France, as well as the factors affecting the price of phosphatic fertilizers during recent years, are discussed in this article.

It is shown that large amounts of basic slag and superphosphate, but little rock phosphate, are used in France. "More than a quarter of a million tons of basic slag are used annually on the grass land, especially where the soil is derived from granite and schists, while about one and a half million tons of superphosphate are used annually on the arable land, and a good deal of phosphate is also contained in the guano applied as fertilizer."

It is stated that the price of superphosphates has usually been lower in France than in England, but now that the French deposits of rock phosphate are giving out it is necessary to look elsewhere for supplies of this material, and the price is therefore increasing. At the same time the price of pyrites, from which the sulphuric acid used in the manufacture of superphosphates is made, has also increased.

Discussing the effect of phosphates on the quality as well as the quantity of farm products, it is pointed out that Müntz has shown that dairy products, particularly butter of the finest quality, are obtained only from pastures exceptionally rich in phosphates, and that Paturel has shown a clear connection between the quality of wine and the supply of phosphates.

The production of phosphate rock in 1911, F. B. VAN HORN (*Amer. Fert.*, 36 (1912), No. 11, pp. 21-28).—In 1911 the total marketed production was 3,053,279 long tons, valued at \$11,900,693, as compared with 2,654,988 long tons, valued at \$10,917,000, in 1910. "This increase was almost entirely in Florida land pebble, though Tennessee also showed a good gain. The average price of all rock showed a falling off, being \$3.90 in 1911, as compared with \$4.11 in 1910."

The business aspect of the kelp proposition, F. P. DEWEY (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 4, p. 311).—This article emphasizes especially the difficulty and cost of gathering and drying the kelp in the preparation of potash salts from this source. Assuming the possibility of in time reducing the cost of gathering to 25 cts. per ton and of air-drying to 15 cts. per ton, and that the iodine will pay the cost of all operations on the air-dried kelp, it is estimated that a ton of potassium chlorid from kelp will cost, laid down on the Atlantic coast, \$28.

Potash lime, its preparation and use in agriculture, MÖLLER ET AL. (*Deut. Zuckerindus.*, 37 (1912), No. 22, pp. 481-483).—Experiments on beets and oats with this material, which is prepared by treating lime with the waste solution from the manufacture of potash, and which contains according to the analysis reported about 48 per cent of lime and 1.4 per cent of potash, are briefly reviewed, indicating a decided fertilizing value. See also a previous note (E. S. R., 26, p. 526).

Carriers of lime, J. W. AMES (*Ohio Sta. Circ.* 123, pp. 135-142).—"A general description of the several forms and of the by-product materials containing lime is presented in this circular."

Sulphur as a fertilizer, A. HERAUD (*Petite Rev. Agr. et Hort.*, 18 (1912), No. 419, pp. 112, 113).—This is a brief article based upon the experiments of Chanerlin and Desriot (E. S. R., 25, p. 519), Boullanger (E. S. R., 27, p. 27), Demolen

(E. S. R., 26, p. 819), and Degruilly, indicating a distinct fertilizing effect of sulphur.

Some results obtained from the use of catalytic fertilizers, G. BERTRAND (*Bul. Assoc. Chim. Sucri. et Distill.*, 29 (1912), No. 10, pp. 681-688).—Plat experiments with various crops indicated beneficial effects from the use of manganese compounds. Aluminum nitrate and sulphate and boric acid were also tested to a limited extent but without decisive results.

Argentina guano, F. P. MAROTTA (*Rev. Indus. y Agr. Tucumán*, 2 (1912), Nos. 8, pp. 363-374; 9, pp. 399-409).—This guano is shown to be low grade, containing only 1.13 per cent of nitrogen and 1.11 per cent phosphoric acid. Its composition is compared with that of guanos from many different sources.

Fertilizing value of sewage sludge at Madison, Wisconsin (*Engin. and Contract.*, 36 (1911), No. 16, pp. 498, 499).—An analysis of dried sludge from the sewage disposal works of this city is reported, showing moisture 1.61, nitrogen 2.23, phosphoric acid 0.67, and potash 1.76 per cent. It is estimated that this sludge has a fertilizing value of \$8 per ton.

Commercial fertilizers, W. J. JONES, JR., ET AL. (*Indiana Sta. Bul.* 156, pp. 135-232, fig. 1).—This bulletin summarizes the Indiana fertilizer law, discusses the fertilizer trade in the State and the results of inspection, and reports analyses of fertilizers examined during 1911 as compared with those of previous years.

It is estimated that the sales of fertilizers in the State in 1911 amounted to 179,829 tons valued at \$1,352,269.27. There is shown to be an extension of the use of fertilizers in the State and a growing tendency to use high-grade fertilizers, to purchase on the plant-food basis, and to use more potash and fine-ground phosphate. The quality of the fertilizers offered for sale were the best since the amended fertilizer law went into effect.

A list of firms offering raw materials for home mixing is given.

Commercial fertilizers, B. H. HITE and F. B. KUNST (*West Virginia Sta. Bul.* 138, pp. 229-273).—This bulletin reports the results of analyses of commercial fertilizers inspected during the year 1911. The report shows "very few really serious failures to use materials of the quality guaranteed.

Fertilizing materials, F. T. SMYTH (*Canada Expt. Farms Rpts.* 1911, pp. 183-198).—Analyses of ground rock, limestones, lime, marl, gypsum, mud, muck, peat, crematory ashes, soot, wheat straw ash, seaweed, and dogfish scrap are reported and discussed.

An act to regulate the sale of commercial fertilizers (*Massachusetts Sta. Circ.* 32, pp. 4).—This is the text of the law approved May 3, 1911. The principal new features of this law as compared with the old are provisions for inspection of agricultural lime; for guaranty of available phosphoric acid in Thomas slag by the Wagner method; an analysis fee of \$8 instead of \$5 each for nitrogen, phosphoric acid, and potash in fertilizers, and \$12 for agricultural lime; registration and payment of fee on or before January 1 instead of May 1; and the retention of duplicate samples by the station for one year.

The American fertilizer handbook, 1912 (*Philadelphia, 1912*, pp. 306, figs. 19).—This is an up-to-date compendium of useful information regarding the fertilizer business, including directories of the fertilizer trade and allied trades, as well as a review of patents relating to the production of fertilizers from 1830 to 1910, and special articles on the following subjects: The National Fertilizer Association; phosphate rock deposits of the United States and statistics of production, consumption, and price of phosphate rock; statistics of production, consumption, and price of potash salts, nitrate of soda, sulphate of ammonia, tankage and blood, and cotton-seed meal; the construction of a modern fertilizer

factory; reviews of the fertilizer materials markets in the United States and statistics of the consumption of fertilizers in the United States as a whole and in the different States; statistics of farm expenditures for fertilizers; the home mixing of fertilizers; a list of the state fertilizer controls; and numerous useful tables giving conversion factors, temperature corrections for hydrometer readings of sulphuric acid, fertilizer formulas, etc.

The world's consumption of fertilizers (*Rev. Sci. [Paris]*, 50 (1912), I, No. 1, pp. 22, 23).—This is a brief note on statistics published by Schneider elsewhere.

The figures are for 1908 and indicate the production in that year of 10,000,000 metric tons of phosphatic fertilizers, the greatest consumers of which were, in the order named, Belgium, Germany, Italy, and France; potash fertilizers corresponding to 500,000 tons of pure potash, the order of consumption of which by countries was Germany, Belgium, United States, France, and Austria; and nitrogenous fertilizers, including both sodium nitrate and ammonium sulphate, 2,500,000 tons, the order of consumption by countries being Belgium, Germany, England, France, and Italy.

Mineral fertilizers in Spain (*Engrais*, 27 (1912), No. 2, pp. 44-46).—It is shown that the use of mineral fertilizers is increasing in Spain, especially in Catalonia, and in 1909 amounted to 292,436,874 kg. (321,680 tons) valued at 47,818,017 pesetas (\$9,228,877.28). The larger proportion of the fertilizers used is imported from England, France, Belgium, and Germany. A few fertilizer factories have been established, of which three in Barcelona are of some importance.

Artificial fertilizer trade (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 100, pp. 369-373).—This is a brief review of the fertilizer trade in Russia, Denmark, Italy, China, Canada, and the West Indies.

## AGRICULTURAL BOTANY.

A text-book of botany.—II. Ecology, J. M. COULTER, C. R. BARNES, and H. C. COWLES (*New York, Cincinnati, and Chicago, 1911, vol. 2, pp. X+485-964+a-q, figs. 535*).—This is the second and concluding volume of the text-book of botany from the Hull Botanical Laboratory of Chicago University (*E. S. R.*, 24, p. 626). The plan outlined in the first volume has been maintained, the work being largely developed from courses in undergraduate study, though in the present volume the authors have included many recent observations and some new points of view.

This new text-book should prove especially adapted to the training of undergraduate students, as it contains the essentials for a foundation for work in almost any field of botany. The authors state that "it is not intended for reading and recitation," but it will doubtless prove suggestive to teachers and will aid students in correlating their observations with each other and with the known facts.

Types of British vegetation, edited by A. G. TANSLEY (*Cambridge, 1911, pp. XX+416, pls. 36, figs. 22*).—This book is the result of the work of the committee founded in 1904 to carry on a survey and study of British vegetation. An effort is made to recognize and describe the different types of plant community existing in the natural vegetation of the British islands, and to trace their relations to climate and soil and to one another. It is believed that the statements made about the relation of soils to the different types of vegetation, which are partly based on analysis and partly inferred, are essentially accurate and afford a sound basis of classification.

The practice of agricultural bacteriology, F. LÖHNIS (*Landwirtschaftlich-bakteriologisches Praktikum. Berlin, 1911, pp. VII+156, pls. 3, figs. 40*).—This book is intended to give a basis for investigations and demonstrations in agricultural bacteriology. An introduction to bacteriological technique is given covering work in the bacteriology of air, water, and feeds; of milk, butter, and cheese; of various fertilizing materials; and of soils. The appendix contains a key to common species of bacteria and practical suggestions for the laboratory. The work concludes with an index.

One thousand American fungi, C. McILVAINE and R. K. MACADAM, revised by C. F. MILLSPAUGH (*Indianapolis, 1912, rev. ed., pp. XXIX+749, pls. 71, figs. 174*).—This book gives descriptions of about 1,000 species of toadstools, mushrooms, and other fungi, with notes on their distribution, habitat, poisonous or edible qualities, etc. Chapters are also given on toadstool poisoning and its treatment, recipes for cooking and preparing mushrooms for the table, raising mushrooms, etc.

Seeds and plants imported during the period from April 1 to June 30, 1911: Inventory No. 27 (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 242, pp. 99*).—This inventory gives the usual data relating to seeds and plants introduced by the Office of Foreign Seed and Plant Introduction during the period indicated. About 900 numbers are included, much of the material having been collected by F. N. Meyer in western China.

Deciduous rootlets of desert plants, W. A. CANNON (*Science, n. ser., 35 (1912), No. 903, pp. 632, 633*).—A study of the roots of many perennials and a few annuals in the vicinity of Tucson, Ariz., showed that they have two sorts of rootlets, which have similar functions but usually an unlike fate.

A description is given of the root system of a desert shrub, *Franseria deltoidea*, in which, it is stated, the superficial roots bear, in addition to the usual type of rootlets, numerous adventitious rootlets in groups of about one-half dozen. These are formed during the moister season of the year and die during the succeeding dry period, seldom, if ever, persisting to form permanent roots. They are designated by the author as deciduous rootlets, and it is assumed that they are perhaps the first absorbing organs to function after the beginning of the rainy season. The rapid formation of these rootlets increases enormously the absorbing surface of the plants without increasing the distance of water transport. The importance of this in the physiology of the plant is quite evident. Nearly all perennials examined as well as some annuals exhibited a somewhat similar condition.

Setting of fruit and seed by cultivated plants, E. ZACHARIAS (*Ztschr. Bot., 3 (1911), No. 12, pp. 785-795*).—The author discusses some of the factors operative in the setting of fruits and seeds by plants under cultivation and the transmissibility of characters acquired during this process. Among such factors the following are mentioned: (1) Stimulation due to rubbing of stamens by insect visitors, declared to be necessary to the production of pollen in some plants; (2) the stimulating effect of pollen from a different plant of the species, carried by insects or wind; (3) a proper balance between vegetative and reproductive activity; and (4) the relations existing between graft and stock. Degeneration and other aspects of heredity are also discussed.

Low temperatures with exclusion of air and viability of seeds, CLEMENS (*Naturw. Ztschr. Forst u. Landw., 9 (1911), No. 9, pp. 402-409*).—The author investigated seeds of the fir, pine, cypress, oak, beech, maple, and ash. The seeds were divided into two series, of which one was kept from the air at a temperature of from 2 to 3° C., the moisture and carbon dioxide being removed as formed. Those of the other lot were kept in a dry room, subject to vari-

ations of temperature comparable to those outside. After varying periods of time portions of these lots were tested as to comparative power of germination in blotting paper, sand, and humus.

The treatment so far as tried showed favorable results, as compared with those from the exposed seeds, in preserving the viability of the seeds of the fir, oak, beech, and maple. The other seeds gave inconclusive or negative results.

**The results of the germination of seed subjected to the action of various solutions, P. LESAGE** (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 13, pp. 826-829).—A brief account is given of experiments with seed of the common garden cress to determine the effect of various solutions on germination. Seed were placed to germinate after soaking in varying strengths of alcohol for periods of from 1 to 50 hours.

The results show that in very concentrated solutions the seed retained their vitality to a considerable extent, while in more dilute ones they were destroyed. In still greater dilutions of alcohol no injury was noted.

A table is given showing the effect of treating seed in from 0.5 to 12.5 per cent solutions of absolute alcohol, the exposure varying from 1 to 50 hours. The strongest solution, even when employed for 50 hours, destroyed only 3 out of 10 seed, while after 6 hours in the 0.5 per cent solution none germinated and only 2 remained alive in the lot that was treated that long. For the 1 per cent solution none germinated after 3 hours' soaking, nor did any germinate after 2 hours' treatment in the 2 per cent solution, but as the strength of the solution was increased the period of soaking could be likewise increased without apparent injury.

The author discusses at length the curve which shows the relation between the strength of solution and the length of exposure, and thinks that possibly some data can be secured on the sterilization of seed without appreciably injuring their vitality. Other experiments are briefly noted in which cress and radish seeds were subjected to solutions of common salt and comparable curves were obtained.

**The effects of caffeine upon the germination and growth of seeds, F. RANSOM** (*Bio-Chem. Jour.*, 6 (1912), No. 2, pp. 151-161).—Caffein in aqueous solutions, varying in strength from 1 to 0.0001 per cent, was applied to various seeds before planting in order to test its effects in retarding or stimulating germination and growth.

The results obtained quite uniformly attest the injurious effects of caffeine. At 1 per cent concentration, germination was entirely prevented in some instances, and both germination and growth were greatly retarded by strengths as low as 0.01 per cent. The only exception, that in case of nasturtium, was ascribed to the density of the seed covering which was supposed to limit the access of caffeine. More dilute solutions of caffeine alone or in association with other substances had no perceptible accelerating effect. The investigations are being continued.

**Water and light as factors in vegetation, T. PFEIFFER, E. BLANCK, and M. FLÜGEL** (*Landw. Vers. Stat.*, 76 (1912), No. 3-6, pp. 169-236, figs. 4).—These investigators carried out in the spring of 1910 a series of 112 experiments on the effects of water and light on growth products of oats, the more significant results of which may be summed up as follows:

The water content of the soil bears a more important relation to the formation of crop products than has yet received adequate recognition. The nitrogen content of the crop is increased with the addition to the soil of this nutritive substance. The establishment of maximum values for the profitable utilization of plant food is considered to be of importance as regards agricultural products. Self-shading through luxuriant growth interferes with the results of other

variant factors, preventing their full expression in augmented crops. The point where this interference begins is difficult to determine. The law of minimum is a straight line function only so long as optimal vegetative factors operate. Larger water utilization affects the relative solid content of crops negatively. About 364 gm. of water was used per gram of dry substance formed above ground.

**Relation of the daily march of transpiration to variations in the water content of foliage leaves.** B. E. LIVINGSTON and W. H. BROWN (*Bot. Gaz.*, 53 (1912), No. 4, pp. 309-330).—Attention was called in a previous publication (*E. S. R.*, 18, p. 328) to differences existing between the time of the maximum evaporating power of the air and the maximum transpiration in certain plants. From a study of the relation of transpiration to variation in the water content of leaves the authors conclude that there can remain little question that green plants when subjected to relatively great diurnal evaporation intensity frequently exhibit a marked fall in foliar moisture content by day and a corresponding rise by night.

The experiments reported were made in Arizona and the authors were unable to compare the conditions with those of more humid and cooler regions. It is stated that, so far as evidence is at hand, it is probable that the cause of this diurnal minimum in foliar moisture rests in the phenomenon of incipient drying, brought about wherever the ratio of water loss to water supply in the leaves is rendered less than unity. Although the experiments would seem to indicate that the external factor which controls this diurnal fall of leaf moisture is evaporation intensity, the true controlling condition, the authors believe, is more probably the ratio of water supply to water loss. The structure of the plant, the moisture conditions of the soil, and the intensity of evaporation and of solar illumination appear to make up the controlling environmental complex.

It is thought probable that the diurnal, nonseasonal retardation of the escape of water vapor from green leaves in sunlight is the effect of a lower vapor tension within the internal atmosphere of the leaves and over their surfaces. This lower vapor tension is brought about by the increased surface tension and decreased evaporation surface which accompanies a lowered water content of the internally and externally exposed cell walls.

The authors think that in the diurnal minimum in the water content of foliage leaves a criterion can be established that may prove of importance to scientific agriculture, in arid regions at least. By this it may be possible to determine indirectly and somewhat simply the status of the water relations of the plant and to foresee the need of increased soil moisture long before the cessation of growth or actual wilting becomes manifest.

**Stimulation movements of plants.** E. G. PRINGSHEIM (*Die Reizbewegungen der Pflanzen.* Berlin, 1912, pp. VIII+326, figs. 96).—This book is intended as an introduction to the study of the physiology of stimulation in plants, being somewhat more full than the treatment usually given in text-books but not so detailed and specialized as that found in more technical treatises. Free movement, protoplasmic streaming movements, growth and turgor movements, and the various tropisms receive separate and proportional discussion. The work concludes with a somewhat full bibliography and an index.

**Nitrogen assimilation under sterile conditions of plants from nitrates, ammonium salts, and asparagin.** G. G. PETROV (*Izv. Moskov. Selsk. Khoz. Inst.* (Ann. Inst. Agron. Moscow), 17 (1911), No. 4, pp. 141-178, figs. 3).—The investigator cultivated maize plants on nets suspended in sterile tubes in a stream of carbon dioxide over nutritive solutions of (1) calcium nitrate, (2) ammonium sulphate, and (3) asparagin. Both stalks and roots were analyzed, and determinations were made of the total nitrogen content, also of that found as

albumin, asparagin, and ammonia. On the basis of the findings from these experiments, in connection with the data of related literature, he reaches the following conclusions:

In the plant tissues the nitrates are reduced to ammonia during the oxidation of carbohydrates. The ammonia so produced taken on the forms of various amid compounds, in some parts, of asparagin; while that absorbed from outside passes over in large part into asparagin. Asparagin is absorbed by the plant and appears as a good source of nitrogen in this series of experiments.

The assimilation of nitrates in plant cells, O. LOEW (*Chem. Ztg.*, 36 (1912), No. 7, pp. 57, 58).—Considering the questions of (1) what is the first transformation product of the nitrates in the manufacture of protein and (2) what factors are operative in the reduction of such nitrates, the author takes the negative view as to the formation of hydroxylamin and the necessity for light as a source of energy for the reduction process. The results of several investigations are presented with his views, in brief as follows:

Previous experiments conducted, supervised, or cited by the author are claimed to show that (1) contact with platinum sponge is sufficient in the absence of light to reduce magnesium nitrate with glucose in an over-saturated solution of potassium hydrate or to reduce potassium nitrate in solution with dextrose; (2) here is a process analogous or similar to one that goes on in the living cell; (3) absence of light did not prevent, nor did access of light accelerate, the reduction of sodium nitrate in the development of *Penicillium glaucum* cultures in a nutrient medium with glycerin; (4) in various roots kept growing in a cool and totally dark chamber the nitrates were steadily decreased in quantity with corresponding increase of protein; and (5) in case of young etiolated barley plants kept 7 days in a nutrient solution containing 0.2 per cent of sodium nitrate, and then for an equal time in cane sugar solution, maintained at 10 per cent strength and at from 10 to 20° C. and half saturated with calcium sulphate, every trace of the nitrate disappeared from the plants in complete darkness with increase of protein, while the control plants showed strong nitrate reaction. It is held that (6) the light energy which breaks up nitric compounds, for example, nitric acid with evolution of nitric peroxid, has its parallel and equivalent in energy developed by the so-called intramolecular (anaerobic) respiration; (7) if hydroxylamin were formed from nitrates through reduction, its toxic influence upon cells, even in highly dilute solutions, would reveal its presence, the same being true also of some other suggested products; (8) the proteins of living cells are so labile that the least disturbance originates a series of changes which extend throughout the protoplasm; (9) the kinetic energy of the living protoplasm, lowering to more stable groupings, is sufficient for the more difficult work of reducing sulphates; and (10) most roots are obliged to utilize their nitrates in the absence of light and they are probably not carried to the leaves for reduction before utilization.

The physiological function of magnesia in green plants, L. BERNARDINI and G. MORELLI (*Rend. Soc. Chim. Ital.*, 2. ser., 3 (1912), No. 13, pp. 349-353; *Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 21 (1912), I, No. 5, pp. 357-362).—In continuation of work previously noted (*E. S. R.*, 21, p. 30; 22, p. 433), the authors here report their conclusion that magnesium probably plays an important rôle in plant development by its combining with phosphoric acid in the formation of both storage and utilization materials. This is said to be evidenced by the behavior of the chlorophyll in relation to changes in the magnesium phosphate and the germination of seeds in the presence of light.

Injurious effects of illuminating gas upon greenhouse plants, E. M. WILCOX (*Ann. Rpt. Nebr. State Hort. Soc.*, 42 (1911), pp. 278-285, figs. 11).—A descrip-

tion is given of the injury to plants in greenhouses at Omaha, Nebr., which is attributed to the effect of gas from a break in a gas main across the street from the greenhouses. Carnations were particularly attacked, and some peculiar manifestations are described.

In the variety Scarlet Glow 3 weeks after the original injury the styles were found projected from the tips of the buds, which did not show any tendency to open. In other varieties the buds that had commenced to open remained closed and the calyx dried over the apparently dead corolla within. Flowers that were open at the time were killed outright.

Defoliation did not occur on carnations, although on many other plants this was the most characteristic symptom noted. Roses, coleus, and geraniums were more or less defoliated and the terminal shoots often destroyed. Considerable injury was noted on different varieties of lily as well as other plants. It is stated that carnation rust was much more abundant on plants subject to the injury than on others, and it is thought that the effect of the gas rendered them less resistant than normally to the attack of parasitic fungi.

The tarring of roads and its effect on the neighboring vegetation, C. L. GATIN (*Ann. Sci. Nat. Bot.*, 9, ser., 15 (1912), No. 2-4, pp. 165-252, pl. 1, figs. 12).—As secretary of the commission appointed to investigate this subject, the author reports at length upon their investigations, experiments, and conclusions. A study was made of the different substances used for the surface treatment of roads, most of them having coal tar as a basis. The literature of the subject is reviewed, and the results of extended series of observations and experiments are given. Some of the features of the investigation have already been noted (*E. S. R.*, 25, p. 128; 26, p. 432).

All the results tend to show that many trees, shrubs, garden plants, and flowers suffer injury from the fumes given off by the tar and also from the dust arising from the treated roads. The injury seems to be proportional to the distance from the road, the amount of travel, percentage of phenol in the compound, and the insolation of the plants. The effect on the plants is shown in the fading of the leaves, which are spotted and blackened. The cells are plasmolyzed, the chlorophyll disappears, and in its place are found drops of oil and tannin. The whole plant becomes stunted, the development of fibrovascular tissues is reduced, and the formation of reserve starch checked. Marked differences in resistance to injury on the part of some plants is noted, those with thick epidermal cells being less injured than others.

Chemical protection of plants against freezing, I. N. A. MAKSIMOV (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 2, pp. 52-65).—From a series of experiments instituted by the author and not yet complete, preliminary conclusions are drawn in substance as follows:

The introduction of organic substances of nutrient character (carbohydrates, alcohols, acetone) into the plant cell may markedly heighten its resistance to cold, even in case of tropical plants. This protective effect is not in direct proportion to the osmotic pressure and the lowering of the freezing point; it is considerably more rapid than the latter change. Different substances protect in different degrees. The sugars stand highest; then come glycerin, the alcohols, and acetone; mannite stands very low in this scale. The removal of the protective contents restores the original degree of resistance.

A new method of cultivating some of the higher plants in sterile media, R. COMBES (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 14, pp. 891-893, figs. 2).—The author illustrates and describes a form of apparatus devised for growing plants, in which the roots are kept in a sterile medium throughout the entire period of the experiment while the aerial organs remain free in the air.

## FIELD CROPS.

[Field crops work at the Canadian experiment stations and farms in 1910], W. SAUNDERS, J. H. GRISDALE, W. T. MACOUN, C. E. SAUNDERS, F. T. SHUTT, H. T. GÜSSOW, J. A. CLARK, R. ROBERTSON, J. MURRAY, A. MACKAY, W. A. MUNRO, W. H. FAIRFIELD, G. H. HUTTON, T. A. SHARPE (*Canada Expt. Farms Rpts. 1911*, pp. 7-9, 21-24, 33, 34, 37-50, 84-100, 122-128, 131, 132, 143-159, 165-168, 177-181, 262-267, 272-274, 295-306, 317-333, 352-380, 397-413, 435-440, 443-474, 480-502, 505, 506, 511-519, pls. 5, figs. 2).—This continues work already noted (E. S. R., 24, p. 432).

The various farms conducted variety tests of corn, oats, 2- and 6-rowed barley, spring, winter, and durum wheat, emmer, spelt, flax, spring and winter rye, millet, peas, grasses, clovers, mangels, turnips, carrots, sugar beets, potatoes, field peas, and field beans. Mixed sowings of peas and various small grains were also tested. Tables state the yields obtained in these tests and the more important cultural and varietal data obtained from some of them.

Dates of sowing and ripening in Alberta of varieties of spring wheat, oats, 2- and 6-rowed barley, peas, carrots, turnips, sugar beets, mangels, potatoes, and corn are reported in tables, together with yields and other data on the crops obtained.

Tables state some of the results of tests of 1,547 samples of wheat, barley, oats, rye, peas, beans, flax, grass, maple, and ash seeds from different Provinces. They were tested to determine the climatic conditions favorable to the production of seed of high vitality, and to test the influence of the character of the season on vitality. Tests of the decrease of vitality of grains through age indicated that the loss is retarded by low temperature. Winter wheat retained a high germinating power longer than spring varieties, but after the sixth year the specimens in both warm and cold storage had almost entirely lost their germinating power. The decrease was striking in the fourth year, and still more marked in the fifth year. Oat varieties showed fairly good vitality for 5 years, but were quite low in the sixth and seventh years.

The results of rotation and fertilizer tests are tabulated as in previous years. The corn, oats, clover hay rotation again gave the highest profit, \$9.34 per acre.

Potato spraying and change of seed experiments gave results in harmony with those of previous years. Seed of 11 varieties grown at Indian Head produced yields averaging 368 bu. 30 lbs. per acre, as compared with 96 bu. and 42 lbs. secured from Ottawa-grown seed of the same 11 varieties.

In the sixth year's work on the effect of soil moisture on the composition of grain it appeared that irrigated barley had a low protein content as compared with that from dry farming plats. Wheat was probably less affected in this particular.

Analyses of turnips, mangels, and sugar beets are reported. Eleven years' analyses of 2 varieties of mangels indicate that their composition is largely controlled by heredity, as the relative position of the 2 varieties always remained unchanged. Among 11 varieties of turnips tested at the Prince Edward Island station, 55 per cent of the roots of Magnum Bonum were affected by club root as compared with from 73.5 to 100 per cent in case of the other varieties.

At the Nova Scotia farm, the addition of 300 lbs. of artificial fertilizers per acre to manure applied to each of a number of turnip varieties gave financial returns ranging from losses of \$4.56 to a gain of \$1.84 per acre as compared with returns obtained from the plats which received only the manure. Similar tests with mangels showed gains ranging from 44 cts. to \$6.60 per acre.

Wheat grown at the Brandon farm from smutty seed treated with either formalin or bluestone by sprinkling or dipping was entirely free from smut,

while the untreated seed produced a crop with 19 per cent of the heads smutted. Home-grown seed of 1 variety of mangels produced over  $1\frac{1}{2}$  times as great a crop as did commercial seed of the same variety, but there was little difference in case of another mangel variety and 2 turnip varieties.

At the Indian Head farm an unpacked acre produced 1 bu. 32 lbs. more peas than did soil packed once with subsurface packer. The oat yield was apparently raised from 81 bu. 21 lbs. to 88 bu. 17 lbs. by packing once, and the barley yield from 64 bu. 28 lbs. to 69 bu. 28 lbs. Barley on soil packed twice yielded over a bushel less than on soil packed only once. The first year's results of a series of rotation tests on summer fallowed land are reported.

On the nonirrigated farm at Lethbridge, land harrowed April 9 yielded 18 bu. 48 lbs. of winter wheat per acre as compared with 16 bu. 15 lbs. on that not harrowed. Wheat sown September 1 and 15 produced heavier yields than that sown on other dates ranging from July 15 to December 1. Sowing at the rate of 75 lbs. per acre resulted in a higher 3-year-average yield than did any of the 7 other rates tested ranging from 15 to 120 lbs. In case of spring wheat 105 lbs. gave the highest 3-year-average yield. From 60 to 105 lbs. of oats and from 75 to 105 lbs. of barley appeared to be the best rates of sowing. Higher potato yields followed planting in rows  $2\frac{1}{2}$  or 3 ft. apart than  $3\frac{1}{2}$  or 4 ft. apart, and 2 ft. apart in the row invariably excelled 1 ft. apart.

On the irrigated farm at Lethbridge, in rate of seeding tests, the highest 3-year-average yields followed sowings of from 75 to 105 lbs. of spring wheat, from 90 to 105 lbs. of oats, and from 45 to 60 lbs. of barley. Alfalfa seeded at the rate of 10 lbs. per acre produced about the same yield as when sown at higher rates up to 30 lbs. per acre. Spring and fall irrigated winter wheat yielded 18 bu. 5 lbs. and 21 bu. 40 lbs. per acre, respectively. A mixture of alfalfa, timothy, and rye grass produced a little higher 2-year-average yield than a mixture of alfalfa and rye grass, and about 0.8 ton per acre more than a mixture of alfalfa and timothy. Soil-inoculated clover produced more than twice as much as that not inoculated and over  $1\frac{1}{2}$  times as much as that inoculated with a laboratory culture.

At the Lacombe farm, in 1910, the highest yield obtained in rate of sowing tests followed sowings of 2 bu. of winter wheat,  $2\frac{3}{4}$  bu. of spring wheat,  $2\frac{1}{2}$  bu. of oats and from  $2\frac{1}{2}$  to 3 bu. of barley. The results of date of sowing tests are also reported, and a table states the yields secured in a rather inconclusive test of acid phosphate, muriate of potash, and nitrate of soda in various mixtures for spring wheat. The use of a surface soil packer apparently increased the barley yields by about 5 bu. per acre. Among 8 varieties or strains of alfalfa, spring sown in 1909, *Medicago falcata* and Grimm from Excelsior, Minn., showed in 1910 that about 100 and 95 per cent of their plants, respectively, had survived the winter as compared with from 20 to 92 per cent among the others tested. Alfalfa inoculated with soil and with a commercial culture yielded 9,216 and 7,552 lbs. of green material per acre, respectively.

[Field crops at the Florida Station], J. M. SCOTT (*Florida Sta. Rpt. 1911*, pp. XX-XXVI, figs. 2).—In a test of 8 varieties of cowpeas, each of which was sown broadcast and also planted in rows and cultivated, Brabham, Peerless, and Iron produced the highest yields. Brabham and Iron were the only varieties found to be resistant to root-knot. Broadcast sowings gave greater yields in the case of 3 varieties, but averaged much lower when all varieties were considered. Broadcasting required 50 per cent more seed but gave a better quality of hay for horses and mules because it was mixed with crab grass.

Among 80 soy bean varieties tested Mammoth, Black, Neilson, Yellow, Canton, and Edwards are noted as worthy of further trial. The Yokohama bean

ripened its seed much earlier than the velvet or Lyon bean and is recommended as a cover crop in citrus groves because it does not produce so rank a growth.

Japanese cane cultivated 2, 4, and 6 in. deep yielded 16.6, 16.5, and 18 tons of green material per acre, respectively, as compared with 17 tons on a plat cultivated 6 in. deep at first and 2 in. deep afterwards. In a test of 8 applications of fertilizers (E. S. R., 24, p. 733), in 1909 much the highest calculated yield of sirup followed an application of 112 lbs. dried blood, 84 lbs. sulphate of potash, and 224 lbs. of acid phosphate. This plat also produced one of the highest yields in 1910.

Hand-selected Lyon bean seed yielded 11.9 bu. per acre as compared with 10.96 bu. in case of seed taken as it came from the huller. The kudzu vine yielded about 2½ tons of cured hay per acre at 2 cuttings, but as the vines made almost no growth after the second cutting, the author believes that 2 cuttings per season is more than the plant will stand. This vine has not given promising results thus far.

The fourth consecutive crop of velvet beans yielded 13.9 bu. of shelled beans per acre as compared with 21.76 bu. on an adjoining plat which had not previously grown velvet beans. White velvet beans yielded 15.23 bu. of shelled beans per acre. Hand-selected seed yielded 11.98 bu. as compared with 16.1 bu. in case of seed taken as it came from the huller.

In a test of 9 varieties of corn, the Station, Evans, Poorland, and Rawls varieties gave the highest yields in 1910. Winter frost injured the guinea grass tested. Guinea grass fertilized with nitrate of soda, muriate of potash, and acid phosphate yielded 3,370 lbs. of cured hay per acre, whereas a plat in which dried blood was substituted yielded but 2,341 lbs. Para grass yielded 2,400 lbs.

Report on the agricultural stations in the Central Provinces and Berar for the year 1910-11 (*Rpt. Agr. Stas. Cent. Prov. [India], 1910-11, pp. 115, pls. 2*).—This is a report of work at the experimental farms at Powarkhera, Nagpur, Akola, Raipur, Telinkheri, Nawagaon, Ramtek, Bhandara, Chanda, and Chhattisgarh, with results largely in harmony with those already noted (E. S. R., 26, p. 232).

At the Powarkhera farm the use of 20 lbs. of nitrogen applied in calcium cyanamid or calcium nitrate was followed in each case by a much higher wheat yield than the same amount of nitrogen applied in saltpeter, ammonium sulphate, a mixture of the two, oil cake, or farmyard manure; by sorghum yields of 778 and 840 lbs. of grain per acre as compared with 570 lbs. on the check plat; and by yields of seed cotton of 221, 204, and 144 lbs. per acre, respectively. A somewhat higher hay yield followed the application of a mixture of 41½ lbs. of superphosphate and 25 lbs. of ammonium sulphate, than the same mixture in addition to 10 lbs. of sulphate of potash, or various other mixtures.

In a variety test of peanuts, Chinese No. 2 and Egyptian produced the highest yields, and the latter is reported as entirely free from the "Ticca disease," which slightly affected 3 varieties. Other work at this farm included work with various implements, oats, wheat, gram (*Cicer arietinum*), rye, sugar cane, soy beans, velvet beans, flax, sesame, pigeon peas, Jalalia, and other crops.

At the Akola farm applications of night soil after the Meagher system applied every third year, bone dust and saltpeter, or 1-year-old pondrette, in amounts supplying 20 lbs. of nitrogen per acre, were followed by 5-year average rice yields decreasing in the order named. Other applications tested were castor cake, dried leaves of trees, calcium cyanamid, cattle dung, and 640 maunds (about 26.28 tons) of tank silt per acre. Equal applications of the same materials were used in other tests with rice, with rather similar results. Planting single seedlings in holes 6 in. apart produced much higher yields than when bunches were planted.

At the Raipur farm the application of 20 lbs. of nitrogen in night soil after the Meagher system was followed by greater yields of rice and higher profits than followed applications of 1-year-old poudrette, castor cake, dried leaves, cattle dung, or a mixture of bone dust and saltpeter. Financial losses followed the use of calcium cyanamid, bone dust, and a mixture of bone dust and sulphate of ammonia in this experiment. The application of 30 lbs. of nitrogen to irrigated wheat resulted in financial losses in each case except when a night soil was used, although the use of castor cake and of 4 applications of calcium nitrate to irrigated wheat was followed by substantial increases in yield.

Applications of 20 lbs. of nitrogen per acre in night soil, bone dust, a mixture of bone dust and saltpeter, and 1-year-old poudrette were followed by greater 5-year average yields of transplanted rice under irrigation than when dung, castor cake, dried leaves, calcium cyanamid, or a mixture of bone dust and sulphate of ammonia were used. Two other tests of the same fertilizers on transplanted rice under irrigation gave somewhat similar results. In case of plantings of 1, 2, or 3 seedlings or bunches of rice seedlings in holes 6 in. apart both the yield and the profit decreased as the number of seedlings per hole was increased.

[Fertilizer and variety tests], E. THOMPSTONE (*Dept. Agr. Burma, Rpt. Mandalay Agr. Sta., 1910-11, pp. 38*).—In a test of bone meal, nitrate of soda, saltpeter, cotton cake, and farmyard manure in various amounts and mixtures as fertilizers for rice, the 3 highest grain yields were produced by the plats to which farmyard manure was applied. In 2 different localities higher grain yields were produced when the paddy straw was plowed under than when it was burned, but still higher yields were secured when 12,000 lbs. of cattle manure per acre was applied. An application of 6,000 lbs. of cattle manure per acre was followed by much greater grain and straw yields than when hemp, jute, or dhaincha were plowed under as green manures.

A greater yield was obtained after dhaincha than after San hemp or indigo used as green manures.

The results of tests of 16 sorghum varieties, 13 peanut varieties, 6 soy bean varieties, 4 cotton varieties, and of a number of miscellaneous crops are reported.

[Crops and green fodder in winter], G. MARKS (*Agr. Gaz. N. S. Wales, 23 (1912), No. 2, pp. 148-155, pls. 2, figs. 3*).—This article reports the results of variety tests of wheat, oats, rye, and barley on 5 farms. The use of 1½ cwt. of superphosphate per acre apparently doubled the yield of oats and almost doubled the yield of a mixture of wheat and vetch.

Cooperative experiments of the department of agronomy, M. F. MILLER and C. B. HUTCHISON (*Missouri Sta. Circ. 54, pp. 151-162, fig. 1*).—This circular gives directions for the use of farmers who cooperate with the station in fertilizer and inoculation tests of alfalfa, variety tests of corn, oats, wheat, and barley, tests of grass and clover mixtures for the Ozark upland, fertilizers for potatoes, and the adaptation of crimson clover and vetch to Missouri conditions are also discussed.

Emergency crops for overflowed lands in the Mississippi Valley, B. KNAPP (*U. S. Dept. Agr., Bur. Plant Indus. Doc. 756, pp. 8*).—A brief review of agricultural problems growing out of the flood of 1912 is followed by suggestions for producing field and garden crops under the unusual conditions following the flood.

Top dressing grass lands.—The sowing of red clover, A. E. GRANTHAM (*Delaware Sta. Bul. 95, pp. 7*).—Suggestions are given on the spring sowing of clover seed and the top dressing of grass land.

In tests at the station, poor land seeded to a mixture of red clover, alsike clover, and timothy in September was top dressed during each of the two succeeding years with nitrate of soda, acid phosphate, and muriate of potash, singly or in various combinations and amounts. Nitrate of soda gave the largest returns when used singly or in combination, and no application without nitrogen paid for the fertilizers used.

Separation of Swiss cereals into different types, G. MARTINET (*Ann. Agr. Suisse, 12 (1911), No. 4, pp. 223-258, figs. 5*).—The author states that Swiss cereals are mixtures of types because of variation, mutation, and hybridization. He states in detail the observations made and the data gathered in separating types of oats, barley, and wheat during the period 1906-1910.

[Small grain varieties recommended] (*Agr. Gaz. N. S. Wales, 23 (1912), No. 2, pp. 137-140*).—These pages present lists of the varieties of wheat, oats, barley, and rye recommended by the department of agriculture of New South Wales. The recommendations were made by experimentalists and managers of the farms of the department in conference with others.

Alfalfa seed production, J. M. WESTGATE, R. MCKEE, and M. W. EVANS (*U. S. Dept. Agr., Farmers' Bul. 495, pp. 36, figs. 14*).—This publication is intended to set forth the best known methods for the successful production of alfalfa seed. The topics discussed include the soil, climatic, and other conditions affecting alfalfa seed production, methods of managing fields, harvesting the seed, utilizing the straw, cultivating in rows for seed, weeds, seed adulteration, and the commercial aspects of seed production, together with notes by F. M. Webster on the insect enemies of alfalfa seed.

The authors have found that the most successful crops of alfalfa seed are produced when a relative shortage of soil moisture accompanies comparatively high temperatures while the seed is maturing. The soil moisture must be sufficient to permit the setting of seed but not great enough to start new vegetative growth for the succeeding crop. This narrow margin is the principal cause of the great uncertainty in the alfalfa seed crop.

Seed 1, 5, and 10 years old gave germination tests of 93, 68, and 44 per cent, respectively. The following table summarizes the results of 5-day tests of seed about 3 months old conducted to determine the proper stage at which to cut for seed:

*Condition of seed as affected by stage of maturity.*

Stage of maturity.	Dead.	Alive.	Hard.	Capable of sprouting promptly.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Pods green and not yet fully filled out.....	94	6	0	6
Pods green but full size.....	73	27	12	15
Pods just turning from green to a light-straw color; plump...	17	83	58	25
Pods turned to a light brown; plump.....	11	89	69	20
Pods turned brown; fully matured.....	9	91	68	23

[Alfalfa seed in color, germination, and structure], E. MACKINNON (*Agr. Gaz. N. S. Wales, 22 (1911), No. 12, pp. 1058-1063, fig. 1*).—The author summarizes earlier work on this subject giving numerous citations to authorities quoted. Yellow seed averaged 92 per cent in germination tests as compared with 44 per cent for brown seed, 9.3 for yellow hard seeds, and 4 per cent for brown hard seeds.

Second generation of the cross between velvet and Lyon beans, J. BELLING (*Florida Sta. Rpt. 1911, pp. LXXXII-CIV, figs. 17*).—The characters of the

first hybrid generation have already been noted (E. S. R., 25, p. 436). From data herein presented on the characters of the second hybrid generation, the author draws conclusions which follow:

Out of 316 plants, 43 were distinctly earlier in flowering than either the Lyon or velvet beans grown in the same field, while 44 were much later. This character evidently segregates. The pods and beans of some plants were much larger than those of the Lyon bean, while those of other plants were smaller than in case of the velvet bean. This character segregates, possibly with two factors.

The hairs on the shoots segregated into dark, velvety, and other mixed or lighter classes which were not readily separable in the field. The ratio of lighter to dark velvety hairs was 256:51. Dark velvety shoots were more or less closely coupled with smooth convex leaves, dark velvety pods, partly with late flowering, and in some cases with abnormal flowers in small bunches, dropping of flowers, few pods to the bunch, and few seeds to the pod. The purple color of the wings and, to a less degree, of the standard segregated in the ratio of 3:1. The hairs on the pods segregated into long stiff, short stiff, and long dark weak hairs with some intermediates.

The lengths of the 5-seeded pods gave a curve divided in the ratio of 3:1. The opening of pods appeared to be a dominant character. The ratio of plants with all closed pods to those with one or more open pods was 1:3. The average weight of one seed reckoned as a percentage of the average weight of a 5-seeded hull gave a number for use in comparison of the proportion of hulls to seeds. This figure is low in the Yokohama bean, higher in Lyon, and highest in the velvet bean. Among 115 segregates it gives a curve with two maxima, one beyond the velvet bean. The average number of beans in the velvet and Lyon pods were about the same, but the plants of the second generation hybrid varied greatly in both directions in this respect.

The crops of good seeds produced by the segregates showed much more variation than did those produced in the same field by parent strains of Lyon and velvet beans. Some plants produced seed which appeared more subject to mold than was the case with either Lyon or velvet, and the same was perhaps true of wrinkled seed. Seeds from different plants, presumably of the same pure line, showed greater variation in average dimensions than did different pickings from the same plant. Bean length was correlated with pod length and segregated in the ratio of 3:1. Breadth and thickness did not visibly segregate independently of the lengths, but the shorter beans were broader and thicker relatively to their lengths than were the long seeds. The average breadth was about the average of the Lyon and velvet strains. Mottling perhaps resulted from 3 independent factors, and the ratio of mottled to unmottled beans was apparently 63:1.

A statement of the technique used in the crossing of stizolobiums is followed by brief notes on pure lines of velvet beans, some corn crosses, and analyses of the juice of West Indian sugar canes. B. 208 stood highest in Brix reading and in percentage of sucrose as indicated by the polariscope.

**Corn production.** G. ROBERTS and E. J. KINNEY (*Kentucky Sta. Bul. 163, pp. 173-200, figs. 4*).—Directions are given for corn production in Kentucky, including soils and fertilizers, seed improvement, cultural methods, and harvesting. Census figures showing the yield of corn in Kentucky in 1909, by counties, are appended.

The results of a test of rates of seeding and methods of planting are regarded as indicating "that in a favorable season 3 stalks per hill will give a higher yield than 2 stalks, and that drilled corn yields better than corn planted in

hills when the rates of seeding are equal." When the corn was drilled, however, planting 12 in. apart, equivalent to 4 stalks per hill, gave a still higher yield in 1910.

Cotton and cotton culture, O. O. CHURCHILL and A. H. WRIGHT (*Oklahoma Sta. Bul. 97, pp. 3-23, figs. 7*).—This bulletin is intended to furnish practical information on cotton culture under Oklahoma conditions. It is based on experimental work at the station, and variety tests are reported.

In 1911, Simpkin Prolific, English Ounce Boll, and Extra Big Boll produced the highest yields and Texas Storm Proof stood rather low, although it stood quite high in average yield among the varieties tested during the period 1903-1910. It is the only variety whose yield is reported for each year during this period.

Directions for cotton production in Oklahoma are followed by a discussion of insect pests and by maps showing the cotton producing area of the State, the average rainfall at the various recording stations, and the dates of the last spring and first fall killing frosts.

Experiments with varieties of cotton, J. N. HARPER and F. G. TARBOX, JR. (*South Carolina Sta. Bul. 162, pp. 3-8*).—Notes on 27 varieties of cotton tested during 1911 are presented.

The seeding of cowpeas, M. F. MILLER (*Missouri Sta. Circ. 53, pp. 147-150*).—Directions for seeding, harvesting, and threshing cowpeas in Missouri.

Thousand-headed kale and marrow cabbage, L. J. CHAPIN (*Washington Sta. Bul. 6, spec. ser., pp. 8, fig. 1*).—The feeding value, culture, and seed production of these crops are discussed, with methods of combating the root maggot. See also a previous note (*E. S. R., 23, p. 436*).

Changes in the composition of the oat plant as it approaches maturity, T. E. KEITT and F. G. TARBOX, JR. (*South Carolina Sta. Bul. 163, pp. 16*).—Analyses of samples taken almost daily from May 11, when the heads were part in bloom and part in boot, until May 26, when the grain was hardening, indicate the changes in composition of the oat plant during that period. The data obtained are presented in tables, from which the following conclusions are drawn:

During the last few days of maturity of the plant the increase in total dry matter was rapid. Prior to that time it was regular but not rapid. From the beginning of blooming to the time of hardening, the seed increased from 17 to 39 per cent of the entire plant by weight, and the leaves decreased from 47 to 28 per cent of the plant. The straw percentage reached its maximum when the oat was in the milk stage. The protein in the seed glume, leaf, and straw increased until the milk stage after which it decreased rapidly. The water content remained high and rather constant during the blooming period, decreased suddenly at the beginning of the milk stage and then remained very constant until the oat began to turn when it again decreased. The ash reached its maximum for the entire plant when the protein reached its maximum. Very little starch formed before the first signs of milk, the carbohydrates being present before that time as invert and reducing sugar, mainly the latter. The sugar percentage decreased during the milk stage but increased slightly with the approach of maturity.

In order to obtain a nitrogenous forage, cutting should be done in the early milk stage, but if a forage high in carbohydrates is sought the grain should be cut at the beginning of the dough stage, since there is a rapid decrease in feeding value after this time in spite of the continued increase of starch in the seed.

The assimilation of phosphorites by oats and buckwheat, V. I. SAZANOW (*Izv. Moskov. Sclsk. Khoz. Inst. (Ann. Inst. Agron. Moscow), 17 (1911), No. 1, pp.*

100-112, figs. 4).—These pages report the phosphoric acid contents of phosphorites from different regions. Pot tests to determine their assimilability by oats and buckwheat on sand and clay soils were conducted, and tables present the data obtained.

A new basis for estimating the value of potatoes, D. ZOLLA (*Rev. Gén. Sci.*, 22 (1911), No. 22, p. 887).—The author suggests the use of the microscope in determining the value of potatoes for specific purposes. Fine grained potatoes should be planted for the table crop. Starch potatoes for manufacturing purposes differ histologically from table potatoes in that their tissues are less compact and their cells large and rich in starch.

Rye selection at Svalöf, 1910, E. W. LUNG (*Sveriges Utsädesför. Tidskr.*, 21 (1911), No. 6, pp. 321-323).—These pages briefly summarize the results of 21 comparative experiments. A table states the grain and straw yields secured, the weight per bushel and per 1,000 kernels, the date of harvest, and the degree of resistance to lodging.

The quality of grain in the season 1910-11, E. SCHAFFNIT (*Illus. Landw. Ztg.*, 31 (1911), No. 99, pp. 911, 912).—Analyses of many rye samples of an abnormal orange-yellow color showed that they were higher in protein content than the usual brown seeds. In germination they tested 98 per cent or over but in growing tests only about 79 per cent.

During this same dry season red, yellowish-red, or even violet-colored straw occurred. It was attributed to the accumulation of carbohydrates or tannic substances due to disturbed metabolism. The violet straw contained 5.8 per cent protein and 1.6 per cent of fat as compared with 3.1 and 1.3 per cent, respectively, in the ripe yellow straw.

The sugar beet in 1911, E. SAILLARD (*Jour. Agr. Prat., n. ser.*, 22 (1911), No. 44, pp. 562-564).—Tables state the chemical composition of sugar beets during each year of the period 1907-1911.

The 1911 crops contained more amid, ammoniacal, and injurious nitrogen than those of preceding years, and the alkalinity during evaporation was less pronounced. Analyses during 1907-1910 indicate that when the ratio of nitrogen to sugar is highest, that of albuminoid nitrogen to total nitrogen is lowest.

Biometrical studies of tobacco varieties, G. RINALDI (*Bol. Tec. Colliv. Tabacchi [Scafati]*, 10 (1911), No. 6, pp. 331-366).—Tables state in full the data gathered in studies comparing some of the principal tobacco varieties throughout the vegetation period. The amount of water required for germination, the amounts retained in the different organs of the plant, and the amounts contained in the plants at different periods of growth are also reported.

The weight of topped plants was greater than that of the untopped plants of the Kentucky, Havana, and Brazil varieties, and was about equal in Herzegovina or Sumatra plants, but in case of Erbasanta and Chinensis, which represented *Nicotiana rustica*, the plants with ripe seed excelled in weight. The author found that Erbasanta and Chinensis had at first a higher dry matter percentage than plants of the 5 varieties of *N. tabacum* studied, but during later vegetation periods they stood below the Havana and Sumatra varieties in this respect.

The early fertilization of tobacco seedlings and their later development, L. MONTEMARTINI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 10, pp. 794-796).—These pages state the results obtained by sowing tobacco seed in April in sand-filled earthen vessels. Different artificial fertilizers were added to the 5 pots in the test and the plants were transplanted late in May. They were set in 2 beds, one of which was well fertilized and exposed to the sun, while the other was shaded and rather sterile.

At the time of transplanting the plants, those that had received Wagner salts seemed best developed, while those that had received a mixture of nitrate of potash and nitrate of ammonia came next, followed by those that had received potassium phosphate. The plants that had been given only nitrate of ammonia lived but a short time after transplanting. Those that had received calcium phosphate appeared weak when transplanted but by August they excelled the others of both beds in height and in size of leaf. The author regards these results as substantiating his earlier conclusions on the value of calcium phosphate as a fertilizer for solanaceous plants when they are making their first growth.

Field experiments with wheat, F. DITZELL (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 2, pp. 122-136).—These pages report rotation, fertilizer, cultural, and method of seeding tests with wheat at the Cowra experiment farm of the department of agriculture of New South Wales.

The effect of carbon bisulphid on the germination of wheat, A. MORETTINI *Staz. Sper. Agr. Ital.*, 44 (1911), No. 5-6, pp. 417-422).—Experiments on 2 varieties of wheat indicated that the use of carbon bisulphid at the rate of 35 gm. per hectoliter did not injure the germinating power unless its action was concentrated on one part of the heap, as when it was poured directly on the grain.

Plant breeding methods, A. HUMMEL (*Fühling's Landw. Ztg.*, 60 (1911), No. 22, pp. 761-780, figs. 6).—The author deals with the relative advantages of mass selection, individual selection, and continued individual selection, and reports tests of these methods in 1910-11 at Neustettin where he worked on the time of flowering of rape and turnips.

Mass selection changed the time of flowering about 1 day, and a combination of individual and mass selection advanced the time of blooming from 1 to 3 days. Tables and curves state in detail the results obtained.

[Seed tests], S. HAMMAR (*Ber. Verks. Skara Kem. Stat. Frökontrollanst.*, 1911, pp. 19-26).—Tables state the results of purity tests and mechanical analyses of seeds of small grains, legumes, and grasses.

Studies with dodder.—I. The germinability of the seeds. II, Infection studies, A. VON DEGEN (*Landw. Vers. Stat.*, 77 (1912), No. 1-2, pp. 67-128, figs. 6).—The author studied in the first series of experiments the germination of the seeds of *Cuscuta trifolii* and *C. suarcolens* as regards time of sprouting under favorable conditions, and in the second the ability of the seeds of *C. suarcolens* to endanger crops by producing plants under the conditions existing in the open fields. The more significant results are as follows:

The germinability of *C. suarcolens* is higher than that of *C. trifolii*, the two being in the experiments made 67.6 and 47 per cent, respectively, of the seeds tested. Both these dodders show a protracted energy of germinability. The greatest percentage of germination occurred in the month of seeding, but thereafter there was a steady decrease to mere sporadic appearances during the 27 or 28 months of observation, and at the end of this time there remained, having neither sprouted nor rotted, 12.5 per cent of the seed of the first and 6 per cent of that of the second species. This delayed germination constitutes a continuous source of danger from these parasitic vines. It is, however, decreased by the fact that germination is retarded by the shading due to luxuriance of the host crops, and is lessened by deep planting, while shallow seeding and the more abundant light after harvest tend to sprout the seeds at such times.

The results obtained in the second series led to the conclusion that clover seed containing not more than 3 seeds of dodder per kilogram is entirely safe for planting, as very few of the parasitic plants may be expected to develop

from such seed. Planting at from 2½ to 4 cm. in depth below the surface is considered sufficient protection in case of clover seeds containing as high as 10 seeds of dodder per kilogram. This species of dodder is a southern plant and is sensitive to low temperatures.

Michigan weeds, W. J. BEAL (*Michigan Sta. Bul.* 267, pp. 277-458, pl. 1, figs. 248).—This bulletin is a companion to Bulletin 260, already noted (E. S. R., 23, p. 439). It describes briefly and illustrates the more important weeds of Michigan, and is intended to aid students and farmers in recognizing some of them. Methods of eradication are briefly discussed.

## HORTICULTURE.

[Horticultural work at the Canadian experiment stations and farms in 1910], W. SAUNDERS, W. T. MACOUN, F. T. SHUTT, ET AL. (*Canada Expt. Farms Rpts.* 1911, pp. 25-28, 101-122, 128-139, 133-135, 198-200, 307-313, 337-340, 388-394, 414-424, 474-476, 502-505, 506, 507, 519-524, 525-530, pls. 3).—This is the customary report on the breeding and cultural experiments with fruits, vegetables, forest and ornamental trees, and herbaceous plants being conducted at the Central Farm, Ottawa, and at the various branch experiment stations and farms in Canada (E. S. R., 24, p. 440).

A number of seedling apples received at the Central Farm for examination are described and descriptions are also given of 13 additional seedling apples originated on the farm. Thus far a total of 720 trees from seeds sown in 1898 and later have fruited. Descriptions of these fruits, whatever their character, have been made and a large amount of data has been thus accumulated. Certain characteristics of 581 seedlings of 11 varieties are presented in tabular form and compared. There appears to be considerable variation between seedlings from the same female parent, the male parentage of the seedlings not being definitely known.

To throw some light on the fruit-yielding possibilities of different varieties of apples, a table is given showing the yields of the best yielding tree of a number of varieties from the third to the twenty-second year after planting. To illustrate the individuality of the trees, yields for the period 1899 to 1910 are also given of a number of individuals of the same variety of apples. Trees grown practically under the same conditions have shown a wide variation in yield.

One of the most promising seedling plums fruiting during the year was the Dara, which is here described. The downy leaved cherry (*Prunus tomentosa*), a bush cherry, is found to be hardier than the tree cherries and promises to be a very useful fruit for the colder parts of Canada. The King red raspberry is proving to be one of the hardiest varieties in the prairie Provinces.

A list is given of the varieties of vegetables which have proven to be most successful in the farm tests. The work of selecting tomato seed to develop superior early strains was continued. The results, as here tabulated, show that all of the selections have progressed in the direction in which the selection was made. In the selection for large early production, the yield has increased each year and the tomatoes selected for earliness have ripened earlier than those selected for productiveness and uniformity without regard to earliness. Improvement in uniformity has not yet been marked.

In the forest belts on the Central Farm, the trees which were planted 5 by 5 ft. apart in plats of single species are in most cases making the best trees from a timber standpoint since the side branches are soon killed out. It is suggested that this distance might be reduced with advantage to 4 by 4 ft. Growth measurements for the period 1907 to 1910 are given for a number of trees planted in various soils and at different distances.

The work at the branch stations and farms consisted largely of variety tests. Analyses of lime-sulphur washes and arsenate of lead are also reported.

**Beginners' guide to fruit growing**, F. A. WAUGH (*New York and London, 1912, pp. 120, pl. 1, figs. 62*).—This work is offered as a simple statement of the elementary practices of propagation, planting, culture, fertilization, pruning, spraying, etc. It also includes chapters on varieties of fruit for different sections and orchard renovation.

**Horticultural statutes of the State of California, 1912** (*Sacramento: State Com. Hort., 1912, pp. 146*).—This comprises the horticultural statutes with court decisions and legal opinions relating thereto, also state quarantine and county ordinances relating to horticulture, and a list of state and county horticultural officers corrected to February 1, 1912.

**Combating orchard and garden enemies**, W. H. CHANDLER (*Missouri Sta. Bul. 102, pp. 239-290, figs. 37*).—The more important insect pests and fungus diseases of fruits and vegetables are briefly described, and directions are given for their control as well as for the preparation of fungicides and insecticides and for protecting trees against rabbits and mice.

**Ampelography of the Crimea**, S. KORSHINSKY (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.), 3 (1910), No. 9-10, pp. 323-478; 4 (1911), Nos. 8-9, pp. 267-458; 10, pp. 465-570, pls. 67, figs. 102*).—A descriptive account of the cultivated varieties of grapes in the Crimea, based on studies conducted in the period 1898 to 1900. A number of self- and cross-pollination experiments conducted with 23 Crimean grape varieties are also described.

The text is accompanied by a number of illustrations showing the character of the fruit and foliage of different species.

**Statistics on the production of grapes and olives in 1911** (*Estadística de las Producciones Vitícola y Olivícola en el Año 1911. Madrid: Govt., 1912, pp. 9*).—A statistical review of the production of grapes, wine, olives, and olive oil in the regions and Provinces of Spain for the year 1911.

**Citrus experiments**, A. W. BLAIR (*Florida Sta. Rpt. 1911, pp. XXVII-XXXI, figs. 3*).—This comprises a progress report on the fertilizer experiments with citrus fruits previously noted (E. S. R., 25, p. 427). Measurements have been made of the trees on each plat 3 times a year and tabular data are given showing the average gain in diameter of the trees on each plat from June 7, 1909, to June 21, 1911.

The experiment thus far does not indicate any marked growth increase in favor of any particular fertilizer used. The clean culture plats on the whole are slightly above the general average in appearance, and some of the trees in the plat which has received no fertilizer are beginning to indicate by a yellowing of the leaves a need of nitrogen. Considerable die-back was observed in the grove in 1910, but no relationship was found between the fertilizers used and the presence or absence of die-back.

**A practical method of artificially ripening Japanese persimmons**, F. E. LLOYD (*Proc. Ala. State Hort. Soc., 9 (1912), pp. 57-63*).—The author reviews Gore's experiments in ripening persimmons with carbon dioxide (E. S. R., 25, p. 744), and summarizes the results secured in his own work at the Alabama College Station during 1911 (E. S. R., 26, p. 327).

**Large scale experiments on the processing of Japanese persimmons; with notes on the preparation of dried persimmons**, H. C. GORE (*U. S. Dept. Agr., Bur. Chem. Bul. 155, pp. 20, figs. 3*).—In previous experiments conducted cooperatively by the Bureaus of Chemistry and Plant Industry (E. S. R., 25, p. 744) it was found that upon keeping unripe persimmons for several days in an inert gas, such as carbon dioxide, they become nonastringent while remaining firm. During the season 1911 these experiments with carbon dioxide were

extended to a semicommercial scale in order to determine the value of the method when applied to the commonly grown varieties of Japanese persimmons. The method used in this work is described in detail and an account is given of experiments in the application of the method to persimmons in Florida and at Washington, D. C. A laboratory method of drying persimmons which has given an excellent product in appearance and flavor is also described.

All of the varieties processed became nonastringent when kept in carbon dioxide, the time required for processing ranging from 1½ to 7 days, depending on the variety. The varieties processed in Florida were subjected to a shipping test. With one exception (the yellow-fleshed Zengi) processing greatly injured the naturally excellent shipping qualities of the fruit, but the Tane-nashi variety was less seriously affected than many of the others.

Contrary to the results noted in the previous experiments, no undesirable effects were produced by high humidity while in process. Processing required a longer time in Washington than in Florida, presumably on account of the lower temperatures. It was found that the softening of the fruit after processing can be considerably retarded by keeping at refrigerator or cold storage temperatures.

The results as a whole indicate that the carbon dioxide ripening process can be recommended generally for treating persimmons for local distribution. Processing may also be successfully employed after shipment.

Covering almond trees for frost protection. A. G. MCADIE (*Mo. Weather Rev.*, 40 (1912), No. 2, pp. 282, 283, figs. 2).—Some experiments in covering almond trees with paper at the university farm, Davis, Cal., during February and March, 1912, are reported and discussed.

The paper used was a weatherproof manila and was first put on at 5 p. m. February 19, and removed at 9 a. m. February 21. It was again put on at 5 p. m. February 25, and removed at 8 a. m. February 26, then again put on at 6 p. m. on February 26 and left on until 8 a. m. March 1. Temperatures were taken both under the cover and outside.

A minimum temperature of 19° F. occurred a little after 8 a. m. on February 26, whereas under the cover the temperature fell to 24°. In general the temperature curves were quite similar, the temperature under the cover being higher in every case. The loss of heat, however, while retarded by the cover, was not sufficiently decreased to warrant extensive use of the method in its present form. Likewise, while there was a difference between the inside and outside rates of warming after sunrise, the rate of warming under the cover was still too rapid. It is suggested that a more effective barrier to insolation can be made by using a double cover with an intervening air space.

Although the almonds were lost the author infers from the experiment that with proper care and improved methods fruits can be protected from the strains incident to rapid loss of temperature and rapid heating, within moderate limits.

Cranberry bog management for Wisconsin, O. G. MALDE (*Wisconsin Sta. Bul.* 219, pp. 3-25, figs. 13).—In a previous bulletin of the station the principles and methods of establishing cranberry bogs were described (E. S. R., 26, p. 841). The present bulletin considers the management of a cranberry bog from the time of planting up to the time of harvesting. The subject matter is discussed under the following general headings: Care of new planting, care of bearing cranberry vines, destroying the weeds, fertilizers for cranberries, protecting bogs from frosts, protection from insects, reclaiming old cranberry bogs, and marketing vines for planting.

Tabular data, based on a circular letter sent out in 1910, showing the average acreage, cost of handling, yield, and profits on Wisconsin cranberry bogs,

are given. The net earnings on clean, sanded bogs were 5 times as great as on semiwild bogs, the increase in yield 4 times as great, and there was a great decrease in the cost of harvesting.

**Ginseng and golden seal growers' handbook**, J. H. KOEHLER (*Wausau, Wis., 1912, pp. VII+116, pls. 41*).—A popular handbook of information relative to the history, uses, market, commercial value, culture, diseases, and insects of ginseng, with briefer reference to the golden seal. The subject matter is based upon the author's experience as a grower as well as on the investigational literature on the subject.

**Status and prospects in ginseng industry**, M. G. KAINS (*Amer. Agr., 89 (1912), No. 24, p. 755*).—A note on the present status of ginseng culture in the United States.

**Lavender cultivation**, J. KNIGHT (*Jour. Dept. Agr. Victoria, 10 (1912), No. 5, pp. 316-321, figs. 5*).—A popular account of lavender culture and the oil extraction in Victoria.

**A practical handbook of trees, shrubs, vines, and herbaceous perennials**, J. KIRKEGAARD (*Boston, 1912, pp. 407, pls. 60, figs. 3*).—The larger part of this work, which is offered primarily as a reference book of hardy ornamental trees and plants, is given up to a tabular description and classification of species, including notes on their important characteristics, uses, and treatment. In addition to the descriptions many of the uncommon or partially known species and varieties are illustrated. Other features of the work include planting lists and plans, general information relative to planting operations, and notes on rose culture and lawn making, together with lists of trees and plants for special purposes.

An article by H. T. Fernald on 'The Insect Pests of Shade Trees and Shrubs' is also included.

**Lawn soils and lawns**, O. SCHREINER, J. J. SKINNER, L. C. CORBETT, and F. L. MULFORD (*U. S. Dept. Agr., Farmers' Bul. 494, pp. 48, figs. 19*).—This comprises an adaptation with revisions of the subject matter in Farmers' Bulletin 248 (E. S. R., 17, p. 976) and Bureau of Soils Bulletin 75 (E. S. R., 24, p. 712).

## FORESTRY.

**Forest conditions in the northern Ozarks of Arkansas**, W. W. BENNETT (*Forest Club Ann. [Univ. Nebr.], 4 (1912), pp. 61-67*).—A descriptive account of forest types occurring in the northern Ozarks.

**Notes on forest conditions in northwestern Nebraska**, R. J. POOL (*Forest Club Ann. [Univ. Nebr.], 4 (1912), pp. 51-60, pls. 3*).—A descriptive account of forest types occurring in northwestern Nebraska.

**Trees of Omaha**, S. V. FULLAWAY, JR., and W. R. CHAPLINE, JR. (*Forest Club Ann. [Univ. Nebr.], 4 (1912), pp. 24-38*).—A contribution to the knowledge of the native and exotic trees of Nebraska, consisting of a list of 171 species, of which 38 are native to the State. The scientific and common name, the maximum diameter and height, and the native habitat of each species are given.

**The catalpas and their allies**, H. GARMAN (*Kentucky Sta. Bul. 164, pp. 203-223, pls. 9, figs. 8*).—The author calls attention to the characteristics distinguishing the western catalpa (*Catalpa speciosa*) from the southern catalpa (*C. bignonioides*). Consideration is also given to the importance of the western catalpa as a wood for fence posts and railway ties, propagating and growing the trees, rate of growth, characteristics of the wood, and enemies of the catalpa. Brief descriptive notes are also given of some related species, including the trumpet creeper (*Tecoma radicans*), the cross vine (*Bignonia*

*capreolata*), and the Japanese catalpa (*C. kammerseri*), together with an account of the trumpet creeper leaf miner (*Octotoma plicatula*) and its control.

Utah juniper in central Arizona, F. J. PHILLIPS and W. MULFORD (*U. S. Dept. Agr., Forest Serv. Circ. 197, pp. 19, pls. 2, fig. 1*).—The Utah juniper (*Juniperus utahensis*), which is considered the most important tree of the woodland forest of central Arizona, is here discussed relative to its distribution, climatic requirements, botanical characteristics, silvical characteristics, growth, volume, yield, utilization, and management.

Quebracho wood and its substitutes, C. D. MELL and W. D. BRUSH (*U. S. Dept. Agr., Forest Serv. Circ. 202, pp. 12, pls. 2, fig. 1*).—This circular discusses the uses and distinguishing characteristics of the quebracho (*Quebrachia lorentzii*), a South American wood yielding a valuable tanning extract, and of the principal woods substituted for the quebracho, and presents a key for their identification.

Cinchona in Java from 1872 to 1907, being extracts translated from the *Scheikundige Bijdragen tot de Kennis der Java-kina, 1872 to 1907*, K. W. VAN GORKOM, edited by D. HOOPER (*Agr. Ledger, 1911, No. 4 (Veg. Prod. Ser. No. 115), pp. 35-106*).—An English translation of the author's pamphlet, abridged and rearranged with special reference to its application to the cinchona industry in India. It comprises a historical account of the botanical, cultural, and chemical investigations which have been conducted in connection with the cinchona industry in Java.

Castilla and its culture, P. OLSSON-SEFFER (*Dept. Landb. Suriname Bul. 27, 1912, pp. 66, pls. 7*).—The late author's English manuscript on the culture and preparation of Mexican rubber is here translated into the Dutch language by J. Kuijper, and a summarized account of Castilla rubber in Surinam is appended, in which Castilla rubber is considered relative to its botany, distribution, species and varieties, cultural details, tapping, preparation of the rubber, and marketing.

A test of daily versus alternate daily tapping of Hevea, C. J. J. VAN HALL (*Teysmannia, 23 (1912), No. 2, pp. 92-99*).—Two lots of 300 trees each were tapped from March 15 to December 14. In the first period lot A was tapped daily and lot B every other day. The tapping was reversed in the second period, resumed in the third period, and again reversed in the fourth period.

The data as here tabulated indicate that daily tapping produces a much higher yield of rubber than tapping every other day.

Notes on bark structure, T. KRUEGER (*Forest Club. Ann. [Univ. Nebr.] 4 (1912), pp. 142-156*).—As a result of a preliminary study of bark structure in a large number of American forest trees, the author presents tentative keys showing the more prominent bark characteristics of each genus as indicated by the limited number of species studied.

A sample dichotomous table for determination of coniferous species, L. PARDÉ (*Rev. Eau et Forêts, 51 (1912), No. 11, pp. 340, 341*).—The author presents a specimen dichotomous key for the purpose of soliciting criticism and suggestions as to improvement.

The equipment and operation of a Prussian seed extracting establishment, A. B. RECKNAGEL (*Forestry Quart., 10 (1912), No. 2, pp. 229-234, figs. 2*).—A descriptive account, based on a personal inspection of a Prussian seed extracting establishment and offered as supplementary to a previous article by Wiebecke on the same subject (*E. S. R., 23, p. 445*).

The economic returns from forestry, with special reference to the Prussian state forests, MARTIN (*Tharand. Forstl. Jahrb., 63 (1912), Nos. 1, pp. 40-58; 2, pp. 79-142*).—A critical study of the construction and application of yield

tables, with special reference to the spruce, pine, and beech, based on an examination of tables prepared by various authorities. The study is discussed under the following general headings: Contents of yield tables, the conception of normal stand, application of yield tables, and the future returns from yield investigations.

Assistance to private owners in the practice of forestry (*U. S. Dept. Agr., Forest Serv. Circ. 203*, pp. 8).—This circular supersedes Circular 165 (E. S. R., 21, p. 444). It discusses the aims and nature of assistance given and contains the regulations governing cooperation with private owners, together with sample application forms.

Some permanent sample plat studies, C. F. KORSTIAN (*Forest Club Ann. [Univ. Nebr.]*, 4 (1912), pp. 115-127, pls. 2).—The author describes in detail some permanent sample forest plat studies which are being conducted by the Forest Service of the U. S. Department of Agriculture in the Sierras.

A method for determining the effects of forests upon run-off in the Rockies, R. D. GARVER (*Forest Club Ann. [Univ. Nebr.]*, 4 (1912), pp. 68-73).—The author outlines a plan for the determination of the effects of forests upon streams.

The effect of forest fires on trees and reproduction in southern New England, P. L. BUTTRICK (*Forestry Quart.*, 10 (1912), No. 2, pp. 195-207, fig. 1).—This paper discusses the factors influencing the resistance of trees to fire, the after effects of a single fire, the effect of recurring fires, fire in relation to sprouting, the effect of forest fires on reproduction, and the effect of age on resistance.

The need of fire protection in the Tropics, C. E. C. FISCHER (*Indian Forester*, 38 (1912), No. 5, pp. 191-221).—A review of the literature on this subject.

Rainfall a factor of tree increment, F. DAVIS (*Forestry Quart.*, 10 (1912), No. 2, pp. 222-228, fig. 1).—Finding that the work of several European investigators appeared to show a correlation between tree increment and the amount of annual rainfall, the author studied tree specimens, principally from New England and the Eastern States, in conjunction with the monthly rainfall records. The results as here tabulated and discussed indicate that rainfall is a great factor in tree increment.

Notes on winterkilling of forest trees, C. P. HARTLEY (*Forest Club Ann. [Univ. Nebr.]*, 4 (1912), pp. 39-50).—This comprises notes on the occurrence and nature of winter injury to forest trees as observed in district 2 of the Forest Service of the U. S. Department of Agriculture, including Colorado, Kansas, Nebraska, part of South Dakota, and Wyoming.

A new method of constructing volume tables, D. BRUCE (*Forestry Quart.*, 10 (1912), No. 2, pp. 215-221).—The author describes a method of constructing volume tables which involves the use of what is termed the "frustum" form factor.

Sand blast tests of New South Wales timbers, W. H. WARREN (*Jour. and Proc. Roy. Soc. N. S. Wales*, 44 (1910), pt. 4, pp. 620-630, pls. 5, figs. 4).—The tests here described were conducted in order to obtain the relative values of timbers for wood paving, flooring, and similar purposes.

On the durability of railroad ties, K. HAVELÍK (*Centbl. Gesam. Forstw.*, 33 (1912), Nos. 3, pp. 105-115; 4, pp. 172-182; 5, pp. 224-233, figs. 5).—This is a review of recent investigations along this line, with conclusions based on a study of the results as a whole.

Quantity and quality of creosote found in two treated piles after long service, E. BATEMAN (*U. S. Dept. Agr., Forest Serv. Circ. 199*, pp. 8, pl. 1, fig. 1).—This circular gives the results of analyses of creosote found in 2

treated piles which had been in the teredo infested waters of the Gulf of Mexico for about 30 years.

One of the piles was perfectly sound, whereas the other had been attacked, particularly at the water line. No treating records were available. The analyses showed that the creosote in the perfectly preserved pile originally contained at least 40 per cent of naphthalene fractions, a large portion of which remained in the wood. The creosote in the less perfectly preserved pile contained little or no naphthalene.

## DISEASES OF PLANTS.

[Report of the botanist on plant diseases in 1910], H. T. Güssow (*Canada Expt. Farms Rpts. 1911, pp. 239, 240, 244-260, pls. 4*).—During the year many diseases have been dealt with, among them rust of grains, mildew of wheat, bitter pit, anthracnose, black rot, bitter rot, rust, and sooty mold of apples, a bacterial blight of English walnut observed at Agassiz, B. C., diseases of plums, cherries, and small fruits, onion mildew, leaf spot of tomatoes, club root of crucifers, also the following which are given especial notice:

A frost injury to wheat is reported to occur on frosty nights on unevenly ripened grain lying freshly cut. The grains shrivel, becoming lighter in weight and darker in color than sound ones, and their germination is found to be lower and more uneven as to time, thus perpetuating the trouble.

A discoloration of the grains in wheat from several widely separated regions is described. The embryo is darkened, and the plant seems to lack vigor. Further investigations in this connection are contemplated.

A peculiar belling of pears with a band of russet corky cells was studied, and is attributed to chilling when young, these parts having been found to lack the coat of fine hairs claimed to give a measure of protection when present.

A new contagious disease of peaches has been observed in the Niagara district, extending into New York State. It manifests itself by cankers on trees of all ages and varieties, attacking and weakening any part so that large branches may be lost through breaking. The disease spreads rapidly, and has quickly become very serious.

Strawberries and raspberries are said to suffer injury during cold nights when in bloom, the frost killing some of the styles and thus causing the fruit to be malformed when matured. Protection by means of hedges or cheese cloth and by smudge fires, also spraying with cold water in early mornings, have been found useful as preventives of this injury.

Potato scab experiments having previously led to results apparently inconsistent, a series of annual tests was entered upon to determine the relative value of the treatments usually prescribed. The crops obtained by planting uniformly but not badly scabbed seed potatoes showed 54.8 per cent of scabby tubers from the untreated seed, 54.5 per cent from the carbonate of soda treatment (10 oz. in 10 gal. water), 53.3 per cent from the corrosive sublimate (1:2,000), and 38.4 per cent from the formalin solution (1 lb. in 30 gal. water). No conclusions are drawn.

Internal spotting of potatoes externally sound, caused by discoloration of the vascular bundles near the stem end, is reported. The trouble appears to be identical with that known as "sprain" in England and as "Eisenfleckigkeit" in Germany. Observers are not unanimous as to its cause. See also another note (E. S. R., 21, p. 447).

Leaf spot of elm (*Dothidella ulmea*) was found to extend back upon the petioles to the tips of the young shoots. These twist downward and are finally

killed, none recovering so far as observed. Removal and burning of all such parts in autumn is recommended.

Other parasitic fungi the occurrence of which is recorded are *Entomosporium mespili* on English hawthorn from Nova Scotia, *Lophodermium nervisequum* on *Abies* sp. from New Brunswick, and *Dasyyscypha willkommii* from Nova Scotia.

**Report of plant pathologist, H. S. FAWCETT** (*Florida Sta. Rpt. 1911, pp. LVIII-LXVII, figs. 3*).—This report summarizes investigations carried on during the fiscal year, the principal studies being made on diseases of citrus trees and in part previously noted (E. S. R., 25, p. 456; 26, p. 449). A number of experiments to control stem-end rot were conducted, but none of the treatments gave beneficial results.

*Diplodia natalensis* has been found to cause gummosis of peach and orange trees. In addition to these host plants, inoculation experiments have been made with the cultures of the organism on 18 species of native trees. The following 6 species produced gum with the killing of tissue: Wild plum, wild cherry, cherry laurel, prickly ash, sweet gum, and sumac. Four additional species showed bleeding with killing of tissue, but no gum. These were basswood, red bud, hackberry, and mulberry. Iron wood and water oak showed slight killing of tissue without any bleeding, while hawthorn, hickory, magnolia, holly, ash, and huckleberry were apparently not affected by inoculation with the fungus.

Brief notes are given on black rot due to *Alternaria citri*, blue mold rot caused by *Penicillium italicum* and *P. digitatum*, scab or verrucosis due to *Cladosporium citri*, and on the brown fungus of the white fly (*Aegerita webberi*).

**Report of plant physiologist, B. F. FLOYD** (*Florida Sta. Rpt. 1911, pp. LXVIII-LXXXI, figs. 5*).—The principal work in the laboratory of plant physiology has consisted of a study of the nutrition and malnutrition of citrus plants, attention being given to some of the diseases that are supposed to be due to malnutrition. Among these are die-back, melanose, yellow spotting, and frenching.

Experiments are in progress with organic nitrogenous fertilizers to determine their effect, especially on die-back and melanose, and in conjunction with these experiments studies are being made on the maximum fertilization of citrus trees, particularly the nitrogen fertilization. Heavy fertilizing has been found to cause disturbances in the nutrition of citrus trees, resulting in the falling of the leaves and fruit, but experiments thus far indicate that the chemical injury shows itself only in the weaker parts of the plants.

Experiments on die-back have been begun in the citrus experimental grove near Tavares to determine the effect of certain fertilizers on the chemical and physical properties of the soil, upon the trees, and upon the quality and quantity of the fruit, and also to study the relation of the fertilizers to insect pests and diseases. The die-back, so far as the plot experiments have gone, seems to be independent of the fertilizers that have been used.

An extended report is given of the investigations on melanose, a disease of citrus trees which is distributed throughout Florida and is also known to occur in a number of other regions. In Australia the disease is claimed to be due to the fungus *Cladosporium brunneo-atrum* (E. S. R., 12, p. 655), but American investigators have never been able to isolate any fungus in cultures made from diseased material. Melanose seems to affect all varieties of citrus trees in Florida, the greatest injury being done to the fruit. The gross and microscopic characters of the disease are described, and the author concludes that it is probable that melanose is not caused by unfavorable growth factors,

but that it is a disease due to some unknown organism. If this organism is a fungus, it is thought that it probably exists only in a vegetative condition, and that its hyphae are very diminutive, making it difficult to distinguish in the host tissue.

Notes on some mildews, E. FOËX (*Ann. École Nat. Agr. Montpellier, n. ser., 11 (1912), Nos. 3, pp. 246-248, fig. 1; 4, pp. 249-264, pl. 1, figs. 5*).—Notes are given on the formation of conidiophores of species of Erysiphaceae; on the presence of two kinds of conidiophores in *Oidiopsis taurica*, a parasite of sainfoin; and on *Oidium alphitoides*, the mildew that has been so abundant in Europe on the oaks within the past few years.

The specialization of *Uromyces caryophyllinus*, E. FISCHER (*Mycol. Ccutbl., 1 (1912), No. 1, pp. 1, 2*).—In continuance of previous work (E. S. R., 24, p. 346), the present brief preliminary report states that the author tested the supposition that this fungus falls into several species living on different hosts. It is claimed that in repeated tests this fungus was successfully cultivated on *Tunica prolifera* but not on *Saponaria ocyroides*, and the conclusion is reached that here are two forms biologically distinct.

Corrosive sublimate as treatment for winter grains, L. HILTNER and GENTNER (*Prakt. Bl. Pflanzbau u. Schutz, n. ser., 9 (1911), No. 9-10, pp. 117, 118*).—In pursuance of studies by the senior author on corrosive sublimate as protection from attacks of *Fusarium*, resulting from infected seed (E. S. R., 25, pp. 548, 652), observations were made on the crop of 1911.

It is stated that the percentage of attack was found not less than in the previous year, notwithstanding it is probable that more sublimate was used in 1911, but the authors claim that the degree of infection was lower. The reports show that in case of early sowings of rye a better stand of plants was obtained from the seed that had been first soaked in the sublimate solution. A later report on this subject is promised.

A wheat head disease, G. FRON (*Jour. Agr. Prat., n. ser., 23 (1912), No. 11, pp. 340-342, figs. 2*).—Illustrations and a brief description are given of a disease of wheat in France said to have been known there for about 30 years, but now becoming serious in some sections. The disease attacks the head. In some cases, only the middle portion is affected, but in severer cases the whole head is deformed and dwarfed, the chaff being flecked with black spots or covered with a dark mycelium which prevents development of all grains except possibly those at the ends of the spike. The affection is ascribed to the fungus *Dilophia graminis*. The author urges further studies of the disease.

Leaf roll of potato (*Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 7, pp. 911-915, pl. 1, fig. 1*).—This is the third report of the committee appointed for the study of this disease. The symptoms are fully described in order to prevent confusion between this and somewhat similar affections. Such means of combating the disease as chemical treatment of seed tubers, disinfection of the soil, and use of special fertilizers, are stated to have been found thus far of negative or at best of doubtful utility. Early removal from the field of tubers from diseased plants and careful culling of seed tubers are recommended as practical measures that are in a degree protective.

The wart disease of potatoes, T. H. MIDDLETON (*Bd. Agr. and Fisheries [London], Ann. Rpt. Intel. Div. 1910-11, pt. 2, pp. 38-54, maps 2*).—The wart disease of potatoes, due to *Synchytrium endobioticum*, is present over a large area covering the west and northwest of England, parts of Wales, and a part of Scotland.

Experiments with about 50 different varieties were carried on in 1910 in different localities to determine their resistance to the disease, with gratifying results. The varieties Langworthy, Conquest, and Golden Wonder were not

at all or only slightly attacked by disease, although the potatoes were planted in soils in which susceptible varieties would not have produced a sound plant. Other varieties contained a certain amount of disease, and the majority were either entirely destroyed or produced very few sound tubers.

Another series of experiments is reported upon in which different soil treatments were tested for the control of the disease, the fungicides used being sulphur, copper sulphate, iron sulphate, Strawsonite, potassium sulphid, etc. In no single plat did the potatoes escape disease, and the number of plants affected was so great that it was not considered worth while to attempt to determine the proportion of affected tubers.

Another experiment was carried on to determine the value of the process of greening the seed potatoes in relation to the disease. It was found that sprouted tubers when planted in soils infected by the fungus were more liable to produce a smaller crop of tubers and were more subject to disease than un-sprouted tubers.

Some fungus diseases of the prickly pear. F. A. WOLF (*Ann. Mycol.*, 19 (1912), No. 2, pp. 113-134, figs. 8).—The author has during the past 3 years made a study of the common diseases of the prickly pear (*Opuntia lindheimeri*), which is used to some extent in south and southwest Texas as a forage crop. The present report considers the structure, cultural characteristics, and life history of the fungi themselves, also the symptomology and the pathological morphology of the prickly pear.

The fungi most common are stated to be *Sphaerella opuntiae*, causing in its conidial stage (called *Glaeosporium lunatum*) an anthracnose; *Perisporium wrightii*, causing the black spot disease; and *Hendersonia opuntiae*, causing the sun scald of prickly pear. Several other disease-causing fungi of less destructive nature are mentioned.

Infection with *S. opuntiae* takes place only following the rainy season in the spring, causing a serious rotting of the new and tender joints. *P. wrightii* is the least common and causes the least injury of these three. *H. opuntiae* is very abundant and destructive. Segments of all ages are affected. The mycelium spreads within the epidermal system, closing the stomata and developing its pycnidia from these stomatal plugs. The scalded appearance is due to the development of suberized tissue as protection from desiccation.

Beet nematodes (*Heterodera schachtii*). O. FUCS (*Ztschr. Landw. Versuchsiv. Österr.*, 14 (1911), No. 7, pp. 923-952).—An account is given of the author's studies on the biology and control of eelworms which attack beets and several other plants. These are said to be migratory and to be carried far and wide in wet weather by moving water, circumstances which increase the difficulties of combating their ravages. The Kühn method of trap-plants is favored but is said to be subject to the drawback that the larvæ remain in the soil to renew the disease thus temporarily checked. Chemical measures have thus far been found ineffective. The plan of heating the soil to the depth usually occupied by the roots to a temperature of 63° C. is said to prove beneficial, but subject to such drawbacks as expense, difficulty of application, etc. A brief bibliography is given.

Tumor formation in sugar beets, K. SPISAR (*Ztschr. Zuckerindus. Böhmen*, 36 (1911), Nos. 1, pp. 1-17, figs. 6; 2, pp. 57-72, figs. 5).—This presents the more important results of the author's continuation of previous work (E. S. R., 24, p. 47). The experiments were undertaken with plants in a less advanced stage of development, with a view to testing his assumption, previously stated, that the tumors result from mechanical injury to the roots.

It is claimed that the attempts to produce the tumors by wounding were successful, that these structures develop from wounds in the cambium, and that

the wounded surfaces develop a callous tissue in which may be differentiated the cambium and vascular elements which grow in relation to the corresponding portions of the roots. The tumors require much nutriment, thus hindering the growth of the plant, while these portions, containing little sugar, are either of little or no value or of positive disadvantage to the crop.

**Melon or cucumber canker**, T. H. MIDDLETON (*Bd. Agr. and Fisheries [London], Ann. Rpt. Intcl. Div. 1910-11, pt. 2, pp. 54-56*).—The canker of melons and cucumbers, due to *Mycosphaerella citrullina*, has become quite serious in greenhouses in England, although the disease does not appear to attack outdoor plants to any particular extent. The results of the investigations thus far conducted on the spread of the disease and the means for its control have been very unsatisfactory, and, according to the author, these points require additional investigation. There seems to be evidence that the fungus gains entrance to plants through wounds, and one of the worst cases reported occurred on plants that had been topped. In other cases the infection seemed to follow insect punctures.

It is believed that thorough disinfection of houses in winter and spraying with Bordeaux mixture might prove efficient in controlling the trouble.

**Collar blight and other collar and root diseases of the apple**, M. B. WAITE (*Rpt. W. Va. Bd. Agr., 1912, No. 25, pp. 66-74*).—The author discusses a form of pear blight attacking the apple at the thickened portion of the tree just above and below the ground line. For this form of the disease the name collar blight is given. Methods for the control of the disease are described and attention called to some other diseases resembling this trouble in some respects. One of the most common forms of the disease is due to winter injury, which favors the attack of wood rot fungi and hastens the death of the tree.

Brief notes are also given on the crown gall, woolly aphid, and the fungus root rot.

**Pear blight control**, E. A. GAMMON (*Mo. Bul. Com. Hort. Cal., 1 (1912), No. 2, pp. 37-41, figs. 3*).—The results of 7 years' active effort in the control of pear blight in a large orchard in California are given. They indicate the necessity of careful pruning and thorough disinfection.

**American gooseberry mildew**, T. H. MIDDLETON (*Bd. Agr. and Fisheries [London], Ann. Rpt. Intcl. Div. 1910-11, pt. 2, pp. 4-27, maps 6*).—The present status of the American gooseberry mildew in Great Britain is discussed. The author states that while this disease is prevalent in certain places in which gooseberry growing is carried on as a commercial industry and has caused serious damage in limited areas, it has not yet spread over the whole kingdom or caused great loss. It is claimed that it may be held in check if proper precautions, such as prompt measures in pruning and spraying, be taken by owners of gooseberry bushes.

Attention is called to the apparent periodicity of the disease in some localities, a severe epidemic one year being followed by a year with little of the disease. This is attributed to the fact that the resting spores of the fungus possibly fail to germinate and carry over to a second season.

**The rusts of wild grapes in India**, E. J. BUTLER (*Ann. Mycol., 10 (1912), No. 2, pp. 153-158, fig. 1*).—Two species of rusts, said to occur on wild grapes in India, are discussed. One is said to agree closely in description with the previously known *Phacopsora vitis*; the other, claimed to be new, is described under the name *Chrysonomyra vitis*. The first is deemed a very active parasite and a possible source of danger to cultivated vines.

**A coconut disease of Mexico**, R. OLSSON-SEFFER (*Rev. Trop. Agr., 2 (1912), No. 4, pp. 295, 296*).—Attention is called to a bud rot disease due to a fungus, said to be *Pythium palmivorum*, which kills the coconut trees in patches of 3

or 4, never on a hillside and always on yellowish clay land. The fungus produces two kinds of spores; one suited to very rapid propagation but short lived, the other capable of surviving for months and infecting distant trees. Cool weather with accompanying rain, fog, and dew favor infection; hence outbreaks occur usually and most freely after such seasons.

The treatment recommended is early destruction of all diseased buds and prompt application of fungicides to points of new infection.

A disease of *Anthemis*, H. BLIN (*Rev. Hort. [Paris]*, 83 (1911), No. 16, pp. 382-384).—A disease of *Anthemis* is reported in France which is said to cause considerable losses to the growers in certain regions.

The foliage first turned yellow, then black: finally the stem was affected and the plant withered and died. The roots were found to be more or less covered with nodules ranging in size from that of a pea to that of a plum, and containing 2 nematodes, *Heterodera schachtii* and *H. radicolica*. The dead and dying leaves were covered with a fungus, said to be *Alternaria tenuis*, which, however, is thought to be a weak saprophyte.

The precise nature and cause of the disease are not yet definitely determined. As treatments, disinfection of the soil with carbon bisulphid, also resting the soil, considerable spacing between the plants, etc., are recommended for the eelworms. For the fungus, Bordeaux mixture applied to the aerial portions is suggested.

A new *Marssonina* on dill, D. HEGYI (*Kisérlet. Közlem.*, 14 (1911), No. 4, pp. 595, 596).—The author describes a disease studied by him on stems, leaves, and flowers of *Anethum graveolens*. He considers it a new species and describes it under the name *M. kirchneri*.

Sweet pea diseases (*Gard. Chron.*, 3. ser., 51 (1912), Nos. 1308, p. 36; 1309, pp. 52, 53; 1311, pp. 84, 85).—The author discusses the disease of sweet peas known as the "streak" disease, due to attacks of *Macrosporium solani*. It is believed that the fungus is carried by seed and that the heavy application of fertilizers used to force sweet peas tends to cause the plants to be more susceptible to attacks of the fungus. The reduction of the large amount of nitrogenous fertilizers, better attention to the preparation of the soil, and the use of sound seed are recommended as means for the prevention of the trouble. Spraying may be resorted to in severe cases, but the foliage sheds the fungicide badly. Treating seed with a potassium permanganate solution is also advised.

The war on the chestnut blight, S. B. DETWILER (*Country Gent.*, 77 (1912), No. 13, pp. 8, 27, fig. 1).—A résumé is given of the papers and discussions at the interstate conference held at Harrisburg, Pa., in February to consider the best methods of dealing with the chestnut bark disease. Delegates were in attendance from Maine, Massachusetts, Connecticut, Rhode Island, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, West Virginia, Ohio, Tennessee, North Carolina, and the Dominion of Canada. Resolutions were adopted recommending prompt and vigorous methods for locating and stamping out the disease in each State so far as practicable. It was also recommended that a quarantine be maintained and that the utilization of diseased chestnut timber be stimulated.

Protection of woods by solutions from injurious fungi, and studies on forms of *Ceratostomella* and *Graphium*, CAROLINE RUMBOLD (*Naturw. Ztschr. Forst u. Landw.*, 9 (1911), No. 10, pp. 429-467, pls. 3; *abs. in Mycol. Centbl.*, 1 (1912), No. 3-4, pp. 115, 116).—In continuance of previous work with wood-injuring fungi (*E. S. R.*, 25, p. 755), the author gives tabulated results of tests of several solutions found to be protective at different strengths. Descriptions are given also of *Ceratostomella* and *Graphium* as affected by different life conditions. Great variations are said to be observable and are pointed to as

presenting difficulties in identification of the species, or in recognition of development stages thereof.

**Studies in dry rot.**—I, **The biology of *Coniophora cerebella*, C. WEHMER** (*Mycol. Centbl.*, 1 (1912), No. 1, pp. 2-10, figs. 4).—This important fungus is of very luxuriant growth, especially in quiet, moist air. It attacks wood of several sorts besides conifers, notably the beech (but not oak), and many other materials, as linen, paper, cotton, etc., which serve as a basis for its development. Its physical characteristics, modes of growth, nutrient relations, and descriptions of its spores are given in some detail.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Some common game, aquatic, and rapacious birds in relation to man, W. L. McATEE and F. E. L. BEAL (*U. S. Dept. Agr., Farmers' Bul.* 497, pp. 30, figs. 14).—Attention is called to the fact that water birds, such as grebes, gulls, and terns, are of greater economic value and do less harm than is ordinarily supposed, while some species, like Franklin's gull and the black tern, are markedly beneficial by their destruction of insects. It is also pointed out that many birds of prey are exceedingly valuable to the farmer, although the opposite is true of Cooper's hawk, the sharp-shinned hawk, and the goshawk, all of which should be destroyed as the determined foes of poultry, game birds, and most of the smaller insectivorous species.

Those here dealt with are the prairie chicken (*Tympanuchus americanus*), California quail (*Lophortyx californica*), ruffed grouse (*Bonasa umbellus*), introduced pheasants (*Phasianus torquatus* and *P. colchicus*), upland plover (*Bartramia longicauda*), killdeer (*Oxyechus vociferus*), horned grebe (*Colymbus auritus*), Franklin's gull (*Larus franklini*), terns (*Sterna maxima*, *S. forsteri*, *S. hirundo*, *S. antillarum*, and *Hydrochelidon nigra surinamensis*), Cooper's hawk (*Accipiter cooperi*), rough-legged hawk (*Archibuteo lagopus sanctijohannis*), sparrow hawk (*Falco sparverius*), long-eared owl (*Asio wilsonianus*), and screech owl (*Otus asio*).

"All the shore birds are strikingly beneficial in their food habits, and the slaughter of these game birds deprives the farmer of valuable allies against some of the worst crop pests. . . . The gallinaceous game birds, as quail, grouse, and pheasants, take far less insect food than the shore birds, yet all of them do a certain amount of good. . . . The hawks and owls have a bad name, but for the most part it is undeserved, and indiscriminate persecution of these birds is a serious mistake."

**Migration of the Pacific plover to and from the Hawaiian Islands, H. W. HENSHAW** (*Auk*, 27 (1910), No. 3, pp. 245-262; *Ann. Rpt. Smithsn. Inst.*, 1910, pp. 545-559).—This paper presents facts relating to the migration of the Pacific plover (*Charadrius dominicus fulvus*), which were gathered in the Hawaiian Islands from 1894 to 1904, together with certain deductions therefrom.

**Third annual report of the state ornithologist, E. H. FORBUSH** (*Agr. of Mass.*, 58 (1910), pp. 165-197, pl. 1).—Among the subjects considered in this report are the following: Destruction of song birds by aliens; birds feeding on the eggs of the gipsy moth; European methods of attracting birds; and the starling in Europe and America, its food, increase and dissemination, habits of driving certain native birds from their nests, etc.

**Digest of the game, fish, and forestry laws, 1911, edited by J. KALBFUS** (*Harrisburg, Pa.: State, 1911, pp. 290*).—This digest includes indexes to the laws.

Notes on the mammals of the Lake Maxinkuckee region, B. W. EVERMANN and H. W. CLARK (*Proc. Wash. Acad. Sci.*, 13 (1911), No. 1, pp. 34).—Observations of 31 forms in the region of Lake Maxinkuckee, a glacial lake about 2½ miles long and 1½ miles wide in the southwest corner of Marshall County, Ind., are here reported.

Destruction of rats in Japan (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 82, p. 86).—A bounty of 2½ cts. gold per head offered by the city of Kobe was claimed for 354,291 rats killed during 1911.

Text-book of protozoology, F. DOFLEIN (*Lehrbuch der Protozoenkunde. Jena. 1911, 3. Aufl. ed., pp. XII+1043, figs. 951; rev. in Amer. Nat., 46 (1912), No. 545, pp. 308, 309*).—A third enlarged edition (*E. S. R.*, 23, p. 357).

Observations upon the morphology of parasitic and cultural amebæ, C. F. CRAIG (*Jour. Med. Research*, 26 (1912), No. 1, pp. 1-37, pls. 2).—The author finds that the organisms here considered, namely, *Entamoeba coli*, *E. histolytica*, *E. tetragena*, and *Amoeba lobospinosa* n. sp., differ greatly in morphology and life history, and that each possesses characteristics which entitles it to specific rank.

Report of the dominion entomologist, C. G. HEWITT (*Canada Expt. Farms Rpts. 1911, pp. 207-235, pls. 3, figs. 3*).—This report includes the text and regulations of the destructive insect and pest act of 1910 and accounts of the brown-tail and gipsy moths, fumigation with hydrocyanic acid gas, insects affecting live stock, particularly the warble fly (*Hypoderma lineata*) and ticks (*Dermacentor albipictus*) on horses, thrips (thought to be *Anaphothrips striatus*) attacking cereals, the white-marked tussock moth, and the narcissus fly (*Merodon equestris*). The narcissus fly is now a serious pest in British Columbia, some 50,000 narcissus and daffodil bulbs having been destroyed near Victoria during the year. The author states that he has found the larvæ of this pest present in bulbs imported into Ontario from Holland.

Brief notes on the more important insects reported to the division of entomology during the year are arranged under the headings of insects affecting field and root crops, fruit and fruit trees, forest and shade trees, and garden and greenhouse. The apicultural work of the year is also noted.

The discovery in 1911 of winter webs of the brown-tail moth at Pomeroy Ridge, Charlotte County, New Brunswick, is said to be the first conclusive evidence of the establishment of this pest in New Brunswick.

Report of field entomologist, G. P. WELDON (*Colorado Sta. Rpt. 1911, pp. 32-34*).—In experiments at Rifle both fall and spring applications of lime-sulphur while the trees were dormant controlled the peach twig borer. The tobacco preparations Blackleaf and Blackleaf 40 were also used in the experiments but proved to be of little value in controlling this pest.

Arsenite of zinc is said to have given promising results in the control of the codling moth, in some cases doing better work than arsenate of lead. Experiments indicate that but little can be accomplished in applying a fall spray for the green peach aphid, unless the application be made very late in the season after the eggs have all been deposited.

*Trichogramma pretiosa*, which was found in abundance the previous year and parasitized as high as 90 per cent of the codling moth eggs, is said to have almost totally disappeared during the season of 1911.

Report of entomologist, E. W. BERGER (*Florida Sta. Rpt. 1911, pp. XL-LVII*).—The author first gives a brief report of the status of fungus diseases of white fly during the year, based on observations at Gainesville, New Smyrna, De-Land, Winter Park, St. Petersburg, the Sub-Peninsula, etc. This is followed by brief accounts of the culture of red *Aschersonia*; germination tests of red and yellow *Aschersonias*; the preservation of fungus in cold storage; soap and

spraying mixtures; weight of white fly pupæ; the woolly white fly; migration of white fly; and scale insects.

Whale-oil soap was found to be a satisfactory agent for use in softening water for use with kerosene emulsion, white fly formula IV, a proprietary emulsion, and a proprietary miscible oil. Some good results were obtained from the use of sodium carbonate in softening water, especially when the mixture of water and soda was allowed to stand for about one-half hour. Borax gave no beneficial results, the oil rising to the surface as readily as when no softening agent had been added.

Applications of lime-sulphur and soda sulphur 1:30 to white fly larvæ in all stages proved ineffective. Tests of the effect of various insecticides on white fly eggs are reported in tabular form. In order to obtain a more adequate idea of the actual drain of the white fly upon the trees, weighings of the nearly mature pupæ were made during March. It is estimated that 1,000,000 pupæ would weigh 67.8 gm. and that this number of larvæ would excrete in a month 15 lbs. of honeydew.

The rufous scale (*Aspidiotus articulatus*) was found to infest a grove near Largo.

Combating scale and other insects, L. TRABUT (*Bul. Agr. Algérie et Tunisie*, 16 (1910), Nos. 7, pp. 149-158; 10, pp. 225-234; 12, pp. 281-293; 16, pp. 377-388; 17, pp. 401-412; 22, pp. 517-528; 17 (1911), Nos. 7, pp. 163-172; 8, pp. 186-202; 9, pp. 224-236; 10, pp. 255-265; 14, pp. 353-360, figs. 127).—This article is devoted largely to the Coccidæ, but also briefly considers thrips, red spiders, and other mites, Aleyrodæ, etc., their parasitic and predaceous enemies, and artificial means of control.

The insect enemies of the prickly pear, H. TRYON (*Queensland Agr. Jour.*, 27 (1911), No. 2, pp. 80-83).—A brief account of the Australian and extra Australian insect enemies of *Opuntia* spp.

Combating the insect enemies of the olive (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 11 (1912), No. 1, pp. 29-38, pl. 1, figs. 3).—This is a report of experiments conducted by the Oleaculture Service in combating the olive fly (*Dacus oleæ*), the olive miner (*Tinea oleæ*), and the olive scale (*Lecanium oleæ*.)

The enemies of the coconut palm (*Bul. Agr. Congo Belge*, 2 (1911), Nos. 3, pp. 512-528, figs. 15; 4, pp. 723-731, figs. 4).—This is a brief account of the insect and other animal enemies and of the diseases of the coconut palm.

Termite studies, N. HOLMGREN (*K. Svenska Vetensk. Akad. Handl.*, 44 (1909), No. 3, pp. 215, pls. 3, figs. 76; 46 (1911), No. 6, pp. 86, pls. 6, figs. 6).—The first part of this work is devoted to the gross and microscopic anatomy and embryology of termites; the second part deals with the classification of the families Mastotermitidæ, Protermitidæ, and Mesotermitidæ.

Grasshopper disease, W. G. SACKETT (*Colorado Sta. Rpt.* 1911, p. 20).—In experiments carried on with a fungus disease, which has appeared sporadically with more or less varying degrees of virulence and has been prevalent among grasshoppers in Colorado, attempts to infect artificially failed. In these experiments grasshoppers were fed with the fungus, a pure culture was spread upon their bodies, and healthy individuals were placed in breeding cages with grasshoppers suffering from or dead of the disease. Pure cultures of the supposed causal fungus have been isolated and attempts have been made to produce on culture media some unusual form of the fungus with which to infect grasshoppers the following season.

On the propagation of the Mexican locust epizootic in Argentina, F. D'HERELLE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 9, pp. 623-625).—Cultures of *Coccobacillus acridiorum* n. sp., the bacterium that was found to destroy locusts (*Schistocerca gregaria*) in Yucatan, as previously noted

(E. S. R., 26, p. 246). have been used by the author with success in destroying crickets and locusts (*S. paranensis*) in the Province of Santa Fé, Argentina. The epizootic spreads with remarkable rapidity, the disease having been reported from a radius of 50 km. (about 31 miles) about the district first infected within a few days after the first infestation.

It is stated that the Argentine government has decided to employ this means of combating locusts in all the infested territory.

The destruction of locusts by Herelle's method, R. GUÉRIN (*Jour. Agr. Trop.*, 12 (1912), No. 129, pp. 70-72).—This paper relates to the investigations noted above.

How to fight the pear thrips, G. E. MERRILL (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 2, pp. 51-59, figs. 3).—This is a general account of the pear thrips, its life history, injury, and control measures.

Excellent results are said to have been obtained from the application of a spray of whitewash, consisting of from 75 to 100 lbs. of lime to each 100 gal. of water. It is stated that the cost of the spray should not exceed more than 1 ct. per gallon of prepared material. Care should be taken to secure first-class lime and to see that it is well slaked. The spray should be applied just as the buds begin to separate and the entire surface of the tree should be covered, one application being sufficient.

Eight times as many pears were obtained from trees sprayed in this way as from unsprayed trees.

Scale insects and black blight, G. AUCHINLECK (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. [etc.] Grenada, 1910-11, p. 15*).—The shield scale fungus (*Cephalosporium locanii*) was found early in 1910 destroying *Coccus mangiferae* in the botanic gardens in Grenada. It has since been distributed throughout the island on mango leaves. The spread of *Cephalosporium* in 1910 and the earlier part of 1911 is reported to have been extraordinarily rapid and it is now present in nearly all the districts of the island, it being difficult to find a mango tree in Grenada on which the scales are not parasitized by this fungus, or which is not clean of black blight.

The red headed fungus (*Sphaerostilbe coccophila*) has been used in connection with scales on citrus trees but so far without success.

European elm scale in California, C. W. WOODWORTH (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 3, p. 191).—This species is said to occur in great abundance in Stockton, Colusa, Palo Alto, Santa Clara, San José, and Ukiah.

African scale insects, L. LINDINGER (*Jahrb. Hamburg Wiss. Anst.*, 26 (1908), *Beiheft* 3, pp. 13-46, figs. 24; 27 (1909), *Beiheft* 3, pp. 33-48, pls. 4; 28 (1910), *Beiheft* 3, pp. 1-38, pls. 3, figs. 16; *Stat. Pflanzenschutz Hamburg [Ber.]*, 11 (1908-9), pp. 13-46, figs. 24; 12 (1909-10), pp. 33-48, pls. 4; pp. 1-38, pls. 3, figs. 16).—Four papers are presented, namely, (1) Diaspidæ from Kamerun, including descriptions of a new genus (*Cryptodiaspis*) and 20 new species; (2) a South African diaspid resembling the San José scale, namely, *Aspidiotus pectinatus* n. sp.; (3) Coccidæ from East Africa, with descriptions of a genus (*Cryptaspis*), 10 species, and 1 variety, all new to science; and (4) Coccidæ of the Canary Islands, a contribution to the fauna of the islands. Thirty-nine species of scales are recorded from the Canaries of which 12 are described as new to science.

Control of the codling moth in Arizona with special reference to the Upper Gila Valley, A. W. MORRILL (*Ariz. Hort. Com. Circ.* 15, 1910, pp. 8).—This circular briefly describes methods of dealing with the pest.

Revision of the oriental Tipulidæ with descriptions of new species, E. BRUNETTI (*Rec. Indian Mus.*, 6 (1911), No. 5, pp. 231-314).—This work includes descriptions of 8 genera and more than 50 species new to science.

A revision of the oriental species of the genera of the family Tabanidæ other than *Tabanus*, GERTRUDE RICARDO (*Rec. Indian Mus.*, 4 (1911), No. 8, pp. 321-397, pls. 4).—"The genera found in the oriental region, besides the large genus of *Tabanus* proper, are: *Hæmatopota*, Meigen, small flies with peculiarly marked wings; *Udenocera*, Ricardo, formed for a species from Ceylon with the long antennæ situated on a tubercle; *Diachlorus*, Macquart, including chiefly species from South America, distinguished by the simple antennæ not situated on a tubercle, by the brown or yellowish markings of the wings and by the curved dilated fore tibiæ, and slender build. One species described from the Philippines is unknown to me. A new genus *Neotabanus* is now added, allied to *Udenocera* in having the antennæ situated on a tubercle, but the antennæ themselves are similar to those of the genus *Tabanus*."

Investigations covering the Mediterranean fruit fly (*Ceratitis capitata*) in the Hawaiian Islands, E. K. CARNES (*Mo. Bul. Com. Hort. Cal.*, 1 (1911), No. 1, pp. 5-13, figs. 2).—The author, who was detailed by the state commissioner of horticulture of California to make an investigation of the infestation in the Hawaiian Islands, to study the life history and habits of the pest, and to work out a plan for its eradication in case the pest should gain entrance and appear in California, here presents a preliminary report. Opportunity is taken to give a summarized account of the pest, its life history, habits, and injury.

Another mango pest in the Philippines, P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 4 (1911), No. 12, pp. 649-652, pl. 1).—A fruit fly, probably *Dacus ferruginous*, destructive to the mango in Java and other parts of Malayasia, is said to have been found in 4 Provinces in Luzon. The author's attention was first drawn to this pest on May 13, 1911, at the Lamo Experiment Station, Bataan.

A note on the habits of the narcissus fly, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London]*, 37 (1911), No. 1, pp. 122, 123).—The author finds that the narcissus fly (*Merodon equestris*) does not restrict its attacks to narcissus, bulbs of *Habranthus pratensis*, from Holland, and *Vallota purpurca*, from Sierra Leone, having been found to contain larvæ of this pest.

First annual report of the state inspector of apiaries, B. N. GATES (*Agr. of Mass.*, 58 (1910), pp. 199-217, pls. 2).—In this report the author briefly discusses brood diseases of bees, the usefulness of bees to the agriculturist, importance of inspection of the apiary, etc.

Pollination of red clover by bumblebees, E. LINDHARD (*Tidsskr. Landbr. Plantcarl*, 18 (1911), No. 5, pp. 719-737, figs. 2).—The author presents a résumé of investigations on this subject, and his own observations which lead him to conclude that the honeybee may occasionally aid in the pollination of clover blossoms. Tables state the results of observations made on the work of *Bombus hortorum*, *B. subterraneus*, *B. distinguendus*, *B. lapidarius*, *B. terrestris*, *B. silvarum*, *B. arvicola*, *B. muscorum*, and *Apis mellifica*.

The natural history of the solitary wasps of the genus *Synagris*, E. ROUBAUD (*Ann. Soc. Ent. France*, 79 (1910), I, pp. 1-21, pls. 4; *Ann. Rpt. Smithsn. Inst.*, 1910, pp. 507-525, pls. 4).—This paper relates to solitary wasps of the subfamily Eumeninæ, which inhabit all of Africa except the northern portion and Egypt.

The Ichneumons of Great Britain, C. MORLEY (*London, 1911, vol. 4, pp. XVI+344, pl. 1, figs. 41*).—This fourth volume (E. S. R., 22, p. 159) deals with the Tryphoninæ, of which the author recognizes 49 genera and 334 species as occurring in Great Britain.

Technical results from the gipsy moth parasite laboratory.—V. Experimental parasitism: A study of the biology of *Limnerium validum*, P. H.

TIMBERLAKE (*U. S. Dept. Agr., Bur. Ent. Bul. 19, pt. 5, tech. ser., pp. 71-92, figs. 10*).—“*L. validum*, a common parasite of the fall webworm (*Hyphantria cunea*), readily attacks the caterpillars of the brown-tail moth, gipsy moth, and rusty vaporer moths [*Notolophus antiquus*], and also the tent caterpillar, when placed in confinement with these hosts, but is able to complete its transformations in the last species only and even then in but a small percentage of cases. Its larvæ seem to be totally unadapted for life in the caterpillars of the 3 former species, and fail to survive the protective reactions of the host, which are visibly manifested by an accumulation of active blood cells or amœbocytes around the larvæ, the cast eggshells, and even the eggs themselves. The amœbocytes presumably attack the living eggs and larvæ, or at least ultimately efface the latter entirely. The same reaction takes place in the case of the tent caterpillar, but a few of the larvæ are able to complete their transformations. Adaptation here is partially in evidence, and may be due to larval secretions which ward off the protective reactions of the host. . . .

“During its whole life the larva feeds on blood and lymph and on small solid particles which result from the disintegration of the host's tissues, probably pathologically induced by some larval secretion. There is no evidence to show that such definite organs of the host as the digestive tube and muscular tissue can be consumed by the larva unless they are broken down, inasmuch as the mouth parts of the larva throughout life are essentially sucking.

“Under artificial conditions the minimum time needed for the development of the insect from the egg to the adult was found to be about 50 days, but the maximum time may be extended many months. Under natural conditions in the Northern States as a parasite of *Hyphantria*, the females are probably active in parasitizing the caterpillars throughout the month of August and the first part of September. The larvæ issue from the caterpillars and spin their cocoons during September and the first part of October, but the cocoons always overwinter, and the adults emerge the following summer.”

A bibliography of 10 titles is appended.

The southern corn root worm in South Carolina (*Diabrotica 12-punctata*), W. A. THOMAS (*South Carolina Sta. Bul. 161, pp. 3-6, pl. 1*).—This bulletin gives a brief account of the life history and remedial measures for the southern corn root worm, or so-called budworm of corn, based upon observations made by the author in eastern South Carolina while prosecuting studies of the cotton root louse in cooperation with the Bureau of Entomology of this Department.

At Marion the first eggs were deposited on March 10 and had hatched by April 2. The larvæ had all formed earthen cells in which to pupate, or transformed to adult beetles by May 5, and the fully developed beetles had all emerged by May 24. During the winter there is no complete hibernation of the beetles in the vicinity of Marion; at the approach of severe cold, they find shelter beneath the leaves of weeds in the fields and in other protected places until it becomes warmer, whereupon they again begin feeding.

The most practical means of controlling this pest is through cultural operations. The planting of corn on low moist bottom lands, to which the pest confines its ravages almost entirely, should be delayed until the larvæ have begun to pupate. The approximate dates for planting corn in the various sections of the State in order to escape the injury occasioned are set as May 5 for lower South Carolina, May 12 for middle South Carolina, and May 19 for the Piedmont Region.

Locomotion of the larva of *Calosoma sycophanta*, A. F. BURGESS (*Ann. Ent. Soc. Amer.*, 4 (1911), No. 2, pp. 173-179, pl. 1, figs. 2).—This is a somewhat

more detailed account than that presented in the bulletin previously noted (E. S. R., 26, p. 350). The apparatus used is described and illustrated.

The distance traveled by a newly hatched larva from 8.30 Saturday morning until its death at 8.45 Tuesday morning, of which time the larva was actually on the recording paper about 70 hours, amounted to 9,058 ft., or 1.71 miles. "The highest rate of travel per minute was during the first  $4\frac{1}{2}$  hours, and averaged 4.9 ft. For the first 24 hours the average was 3.69 ft. per minute; during the next 8 hours the average dropped slightly and for the remaining period the average was gradually reduced until the larva died. . . . For the first 36 hours the larva traveled almost continuously, stopping only occasionally for a minute or so to rest. . . . Although the distance traveled is probably much greater than what would actually occur in nature, it is remarkable that so much latent energy can be stored up in an egg of one of these beetles."

"The length of life of the insect is also worthy of note when it is remembered that no food or water was supplied, as it indicates that the young larvæ are able to survive several days in the field without food and still have sufficient vitality to make a thorough and active search for their prey."

Collecting ladybirds (Coccinellidæ) by the ton, E. K. CARNES (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 3, pp. 71-81, figs. 7).—This is an account of the work conducted in California, where each year several tons of coccinellids of the species *Hippodamia convergens* are collected and distributed to growers of cantaloups, prunes, apples, pears, vegetables, seeds, and garden truck for the destruction of aphids, even including city street trees and home gardens. "Starting about November 1, the field men go up into the mountains to locate the hibernating colonies, which are usually found among pine needles on sunny, well drained slopes, usually in close proximity to running water. . . . By this time the ladybirds have begun to arrive in the mountains and to assemble in colonies on the stems and about the roots of low growing plants, previous to seeking winter shelter of the pine needles, where they are securely hidden." The collecting of lady beetles commences the last of December and continues until the last of February. Two men usually work together, and with fairly good success collect from 50 to 100 lbs. of beetles in a day.

In order to avoid the heavy expense of artificial cold storage, the beetles are kept at the mountain packing house as long as possible and are then transferred to a large cold storage room rented from a commercial company at Sacramento, and kept at a temperature of slightly under 40° F.

Notes on the Ixodidæ of Brazil, H. DE BEAUREPAIRE ABAGÃO (*Mem. Inst. Oswaldo Cruz*, 3 (1911), No. 2, pp. 145-195, pls. 2).—This paper includes tables for the separation of 46 species of ticks occurring in Brazil, a list of their hosts, and their geographical distribution. Ten forms are considered, 3 of which, *Ornithodoros rostratus*, *Amblyomma pacæ*, and *Hæmaphysalis leporis proxima*, are described as new to science.

Notes on the genus *Rhipicephalus*, with the description of new species, and the consideration of some species hitherto described, C. WARBURTON (*Parasitology*, 5 (1912), No. 1, pp. 1-20, figs. 12).—Three species and 1 variety are described as new to science.

Notes on ticks.—II, New species (*Amblyomma*, *Hæmaphysalis*); *Ixodes putus*: Description of the hitherto unknown larval stage, G. H. F. NUTTALL (*Parasitology*, 5 (1912), No. 1, pp. 50-60, figs. 9).—This paper includes descriptions of 3 species new to science, namely, *Amblyomma darlingi*, taken from a deer (*Odocoileus* sp.) and a turkey buzzard (*Catharista atratus*) in the Canal Zone; *Hæmaphysalis warburtoni*, and *H. montgomeryi*.

## FOODS—HUMAN NUTRITION.

Report of the commission to investigate the subject of the cold storage of food and of food products kept in cold storage (*Boston: State, 1912, pp. 308, chart 1*).—After an exhaustive study of the subject the commission reached a number of conclusions and made recommendations.

“In general, the commission recognizes that cold storage is a fundamental necessity in the distribution of the food supply of the nation. In the first place, it enables perishable food products to be brought to market with the least possible deterioration; in the second place, it enables the surplus of such products in the season of natural plenty to be carried over to meet the demand in the season of natural scarcity. The latter is the principal economic function of cold storage. It acts as a means of distributing the seasonal output of perishable foodstuffs evenly over the market year, thus helping to equalize supply and demand.”

The general conclusions reached are thus summarized:

“A progressive deterioration takes place in perishable food products kept in cold storage; the changes naturally occurring are greatly retarded by refrigeration, but are not absolutely suspended. Therefore, a food product that has been held in cold storage is never just as good as the perfectly fresh article, other conditions being equal.

“The deterioration taking place during cold storage first appears in a change in flavor, which may affect the palatability of the food, but does not necessarily affect its wholesomeness or nutritive value.

“The length of time during which an article of food held in cold storage can be kept wholesome and fit for consumption varies for different commodities. The period of proper preservation for any particular commodity depends largely on the methods of handling and preparing for cold storage. Scientific investigation in this field has not yet been carried far enough to enable one to fix normal time limits of cold storage for different commodities.

“On the whole, prolongation of cold storage beyond one year, even under correct conditions, appears to be undesirable, and prejudicial to the public health.”

With respect to regulation, the commission recommends:

“Cold storage warehouses should be subject to the supervision of the state board of health, and should be required to take out licenses and submit regular reports. The main object of the proposed inspection is to ensure the proper condition of goods upon entry into storage and their proper treatment during the storage period.

“Food products deposited in cold storage should be marked with the dates of receipt into storage and of withdrawal from storage. . . .

“The time for which food products may be held in cold storage should be limited to 12 months, with discretionary power vested in the state board of health to extend the time limit for particular consignments of goods, and also to fix a shorter time limit than 12 months for any article of food, if such further restriction of the storage period should be found upon investigation to be desirable. . . .

“The fraudulent sale of cold storage products as fresh goods should be prohibited. It is generally admitted that the purchaser has a right to know whether he is getting cold storage or fresh food. . . .

“The return to cold storage of goods that have once been withdrawn and placed on the market for sale to consumers should be prohibited. Such goods are presumably not in fit condition for further storage. The prohibition of

restorage is needed to protect consumers against a practice that unquestionably leads to abuses."

A dissenting opinion is presented by two of the commission with reference to the marking on each package of the date of delivery by cold storage companies.

Supplying a large city with foodstuffs, with particular reference to market conditions in Berlin, E. LANGE (*Staats u. Sozialwiss. Forsch.*, 1911, No. 157, pp. VIII+83).—Statistical and other data are summarized and discussed, and a bibliography is provided.

The preparation of Westphalian hams (*Jour. Roy. Soc. Arts*, 60 (1912), No. 3092, p. 416).—Juniper is used in smoking the meat, the twigs and berries being thrown into a beech wood fire. The juniper imparts a distinctive flavor, it is believed. The smoking process requires on an average about 8 days.

A protein body in Liebig's meat extract, K. MAYS (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 78 (1912), No. 1, pp. 37-52).—The author has isolated and determined the properties of a body present in meat extract which he concludes to be a proteid.

Since the extract is used in small quantities at a time and as a condiment and stimulant, the presence of a small proportion of protein, in the author's opinion, has no special importance from the standpoint of nutritive value. On the other hand, he believes that it is an essential constituent since it favorably influences the consistency of the meat extract.

The chemical composition of human milk as shown by recent analyses, E. SCHLOSS (*Monatsschr. Kinderheilk.*, 9 (1910-11), pp. 636-640; *abs. in Zentbl. Expt. Med.*, 1 (1912), No. 1, p. 14).—Contrary to the generally accepted opinion, the author maintains that human milk has a constant composition. The fat content varies, but all the other ingredients maintain a definite relation. He presents a compilation of 8 analyses.

Influence of age on wheat and flour, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1911, pp. 168-171).—Continuing earlier work (E. S. R., 24, p. 465), the composition and bread making quality of wheat stored for 2 years were studied.

In general, no differences or changes were noted in chemical composition of the samples stored as flour, though there was a tendency in the gliadin and the gliadin ratio to increase. Conclusions regarding the gluten were not drawn.

Five of the 7 samples stored as wheat showed slight increases in protein content; the gliadin values were very similar to those obtained in the earlier work.

A consideration of the nitrogen-and-ash-free extract and the volume of the loaf did not indicate that there was any relationship between these values, the contention that the volume of the loaf increases with the amount of extract not being supported by the data reported. Furthermore, no relationship was noted between the ratio of soluble ash to total nitrogen and the shape of the loaf.

Chemical analysis and composition of imported honey from Cuba, Mexico, and Haiti, A. H. BRYAN, A. GIVEN, and S. SHERWOOD (*U. S. Dept. Agr., Bur. Chem. Bul.* 154, pp. 21).—The results are reported and discussed, in comparison with American honeys, of 33 samples of Cuban, 23 samples of Mexican, and 16 samples of Haitian honeys. The methods followed in the investigation are described.

According to the authors' summary, the results seem to show that "beyond a slightly greater moisture content and a somewhat lower percentage of sucrose there are no pronounced differences in chemical composition between the honeys of America and those from the countries specified. Other points, however, must be considered."

Attention is directed to the fact that American foul brood is prevalent in Cuba and that while honey from infected colonies of bees is not injurious to human beings, the danger to bees constitutes a serious objection to the unguarded importation of Cuban honeys and affords an additional reason for barring from importation undesirable Cuban honeys.

Furthermore, as pointed out by the authors, "the preparation of the honey for shipment was very poor. The extraction had been carelessly carried out, and much dirt was present in the samples as received. . . . The honey is mostly wild or that from wild bees, is scooped out of the trees by the natives, allowed to drain through coarse cloth, and shipped either in tins or barrels. In only two cases was the product such as could be sold for direct consumption, these two being comb honey.

"Again, with few exceptions the flavor was rank and strong, so that it could hardly be considered palatable. There is some honey of good flavor produced in these places, but it is not exported in any quantity.

"Considering the physical condition of the samples as received in nearly all cases, it can be said that they were not fit for human consumption. Reextraction, straining, etc., might improve this condition, but it is a question whether even under this treatment the honey is made fit for table use, as the dirt has become so intimately mixed as not to be removed by physical means."

A bibliography of chemical literature of honey from 1907 to 1911, compiled by A. H. Bryan, is appended to the report, and supplements earlier compilations (E. S. R., 19, p. 1058).

The nitrogenous constituents of fungi, CAMILLE REUTER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 78 (1912), No. 3-4, pp. 167-245).—In addition to an exhaustive summary of data previously published, the author reports the results of extended investigations.

The hydrolysis of protein from fungi yielded the following amino acids: Glycocoll, alanin, valin, leucin, phenylalanin, prolin, aspartic acid, and glutamic acid. Especially to be noted is the high content of the two low amino acids and prolin. After digestion with trypsin tyrosin was found. From dried fungi the following bases or amino acids were isolated: Guanin, adenin, hypoxanthin, trimethylhistidin, cholin, trimethylamin, putrescin, guanidin, phenylalanin, leucin, and racemic alanin. Especially noteworthy is the occurrence of racemic alanin, which constitutes the greater portion of the free amino acids present.

As the author points out, cases of poisoning often occur after eating edible fungi which are attributed to the formation of toxic compounds by bacteria. It is also possible that in processes of digestion substances with marked physiological properties such as agmatin, paraoxyphenyläthylamin, and imidazolyläthylamin are formed by cleavage from the amino acids and bases primarily formed from the protein.

In the author's opinion it would be especially important from a biological standpoint to study the ferments present in fungi which induce carbohydrate cleavage and play a very important rôle in the formation of the simple plant bases which are physiologically active.

The presence of glutamic acid in preserved tomatoes, N. MONTI (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 11-12, pp. 813-823; *abs. in Chem. Zentbl.*, 1912, I, No. 7, p. 501).—By a method which he describes the author isolated glutamic acid from preserved tomatoes, the quantity being in the proportion of 80 gm. per 60 kg. of material.

[Food inspection and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1912), No. 4, pp. 49-55, 58-80).—The results of the examination of a number of miscellaneous food

products as well as the results of a study of headache powders are reported. Some data are given regarding lard and lard substitutes and other food and drug matters.

Notice of judgment (*U. S. Dept. Agr., Notice of Judgment 1455, pp. 57*).—This notice of judgment has to do with the alleged adulteration and misbranding of coca cola. Some analytical data are included.

Food values—practical tables for use in private practice and public institutions, E. A. LOCKE (*New York and London, 1911, pp. VII+110*).—In this small volume the author has briefly discussed foods and their uses and similar topics and has presented a large amount of data in tabular form, including the equivalents of weights and measures used in connection with foods and dietetics, the composition of prepared and cooked foods and of alcoholic beverages, and the average composition of American foods in general.

As the author states in his preface, "information has been drawn largely from the numerous reports of investigations made under the direction of the United States Department of Agriculture."

The book is provided with an index.

Directions for preparing diet for health and disease, G. REYMANN (*Diätetische Kost-Vorschriften, zum Gebrauch in gesunden und kranken Tagen, Lautercken, 1911, pp. 411*).—General questions of dietetics are discussed and lists are given of the foods in season during different months of the year, together with a large number of recipes and a collection of menus for normal diet and for diet for diabetics and those suffering from liver, kidney, and nervous diseases, from gout, from obesity, and from diseases of the digestive tract, the various diets being arranged in parallel columns. A large number of menus for different seasons are also presented, as well as menus for special occasions.

A bibliography is given of books which the author considers useful, and a list of German periodicals which deal with the preparation of food and similar topics.

[Artificial feeding and poverty and the rate of infant mortality], M. GREENWOOD and J. W. BROWN (*Jour. Hyg. [Cambridge], 12 (1912), No. 1, pp. 5-45*).—The authors discuss particularly the effects of artificial feeding and poverty upon birth-rate and infant mortality. Of special interest is the discussion of the handling and use of statistical data. A bibliography is included.

Concerning the influence of the extractives of meat upon the digestibility of vegetable food, H. WOLFF (*Ztschr. Klin. Med., 74 (1912), No. 3-4, p. 303; abs. in Zentbl. Biochem. u. Biophys., 13 (1912), No. 1-2, p. 21*).—From experiments which were made with dogs the author concludes that the addition of meat extract favorably influenced digestion and nitrogen metabolism.

The increased fat excreted in the feces when meat extract was taken is thought to be fat produced by the organism as a result of stimulation by meat extract and not as undigested from the diet.

The effect of a diet of polished rice on the nitrogen and phosphorus of the brain, C. FUNK (*Jour. Physiol., 44 (1912), No. 1-2, pp. 50-53*).—Experiments were made to ascertain whether differences could be detected between the contents of nitrogen and phosphorus in the brains of normal pigeons and those suffering from polyneuritis, produced by a diet of polished rice.

"The analysis of the brains shows a sensible diminution from the normal of nitrogen and phosphorus content, in a proportion which suggests a breakdown of the lipoids of the brain."

The physiological effect of benzoic acid and sodium benzoate, V. GERLACH (*Physiologische Wirkungen der Benzoesäure und des benzoesauren Natron, Wiesbaden, 1909, pp. 8+95, pls. 10*).—The results of extended experiments are

reported upon the preservative properties and toxic effects of benzoic acid and the effects of benzoic acid and sodium benzoate upon the heart, the red corpuscles, and blood pressure. The results of digestion experiments, including tests *in vitro*, with small animals and man, and of metabolism experiments with man are presented.

The conclusions which the author reached were in effect as follows:

Benzoic acid and sodium benzoate, even in quantities as low as 1 to 1,000, acted as a preservative with chopped meat, and also prevented mold formation on oleomargarine for 52 days.

Cold-blooded and warm-blooded animals (frogs and rabbits) were able to bear, even for a long period, considerable quantities of benzoic acid and sodium benzoate supplied in different ways. When 1 gm. sodium benzoate per kilogram of body weight was injected into rabbits for 12 days no loss in body weight was noted. Larger doses temporarily lowered body temperature. No effect was noted on respiration and pulse. When 2.2 gm. or more of sodium benzoate per kilogram of body weight was used the animals died. When 5 gm. benzoic acid, or 7 gm. sodium benzoate, was fed at a time with 500 cc. of milk to a dog of medium weight, respiration, pulse rate, and body temperature were not noticeably affected.

In an experiment of which the author himself was subject 10 gm. benzoic acid taken within  $3\frac{1}{2}$  hours produced no noticeable effect upon respiration, body temperature, digestion, or general condition.

When from 0.5 gm. to 1 gm. sodium benzoate per day was taken for 44 consecutive days no effects were noted and body weight remained normal in all the subjects. Respiration, pulse, and body temperature were not noticeably affected when 1 or 2 gm. benzoic acid or sodium benzoate was taken.

Benzoic acid and sodium benzoate affected the red blood corpuscles in the same general manner as acids and salt solutions, respectively.

Injections of 4 cc. of a 5 per cent solution of sodium benzoate had no effect upon the heart frequency of a frog, nor did the injection of 1 cc. of a 20 per cent solution given within an hour.

Sodium benzoate intravenously injected into a suspended frog heart had less effect than sodium chlorid solution of equal concentration. The same was found to be the case in experiments with surviving cat heart. In the case of rabbits the blood pressure was influenced only very slightly and temporarily.

As shown by the experiments reported, neither gastric juice, trypsin, nor diastatic ferments were affected by the addition of benzoic acid or sodium benzoate. In the case of a dog with a Pawlow fistula no effect upon the quantity supplied or the digestive power of the gastric juice was observed when 3 gm. benzoic acid, or 5 gm. sodium benzoate, was taken.

As shown by a test breakfast, withdrawn after an hour, the author himself being the subject, 0.5 gm. benzoic acid, or 1 gm. sodium benzoate, did not influence the amount of free hydrochloric acid, the total acidity, or digestive power.

No effect was noted upon the protein condition of the body or the digestibility of protein and fat in experiments with men, when 1 gm. benzoic acid, or 1.5 gm. sodium benzoate, per day was taken for 6 days.

Daily doses of 1 gm. benzoic acid taken for 82 out of 86 and 88 out of 92 days did not cause any noticeable effect upon general condition, body weight, etc. At the conclusion of the test it was found that benzoic acid taken either with a mixed diet or with a vegetable diet was fully converted into hippuric acid.

The literature of the subject is discussed at length and a bibliography is appended.

**Calorimetric observations on man, J. S. MACDONALD** (*Jour. Physiol.*, 44 (1912), No. 1-2, pp. IV, V).—A brief account is given of a calorimeter modeled on the Atwater-Rosa-Benedict apparatus devised at Middletown, Conn., having the same general dimensions, and protected from surface loss or gain of heat in the same manner. The calorimeter is not equipped to deal with the respiratory exchange of gases and is therefore not a respiration calorimeter.

"Departures from the original model have been made, notably in an extension of the internal radiator system and the insertion of an additional internal source of heat. The latter arrangement is used as a compensating system whereby the total heat measurement is maintained as far as possible a constant. The heat output of the subject is found by subtracting from this the momentary values for the heat output of the compensating system.

"This change in method is due to experimental observation of a definite relation between the temperature of the calorimeter ( $T_c$ ) and the mean temperature of the internal system ( $T_r$ ) such that the heat measured by reference to the temperature and quantity of the water stream =  $k(T_c - T_r)$ .

"The value of "k" in this calorimeter was such as to render difficult all attempts to follow abrupt variations in the subject's heat output. Thus when a period of work interrupted a period of rest it became evident that  $T_c - T_r$  must have a new value of perhaps  $5^\circ$  C., entailing a sudden change in the temperature of the water entering the radiator system of  $10^\circ$  C. Because of the slow rate, and the lack of precision, with which such alterations in temperature could be obtained the preceding method was adopted."

The data obtained every 5 minutes throughout an experiment are of three kinds: "(1) Heat stored in, or lost from, the calorimeter walls as inferred from observed variations in temperature; (2) heat removed by water traversing an internal radiator system; (3) heat stored in a change of state in water, and measured by reference to the excess aqueous vapor leaving the calorimeter in the air stream."

Experiments have been performed with a number of subjects under alternating conditions of work and rest and in two instances with a subject asleep.

According to the author, the most interesting features of the results obtained, briefly stated, are as follows:

"The performance of work entails an increased heat output which gradually rises toward a maximum reached at the end of about  $1\frac{1}{2}$  hours. This maximum is then maintained until the cessation of work.

"In order to discover the degree to which this initial portion of the heat output curve is rendered gradual by a storage of heat in the subject's body as evidenced by a coincident rise in body temperature, the latter has in the most recent of these experiments been measured . . . [by a thermocouple method]. We have not, so far, found sufficient variations in temperature to explain the whole effect, though their nature is always such as to explain some fraction of this. It would appear, then, that the 'efficiency' diminishes as the temperature of the body increases."

**A new calorimeter for small warm-blooded animals, A. V. HILL** (*Jour. Physiol.*, 44 (1912), No. 1-2, pp. I, II).—A small calorimeter for warm-blooded animals is described, the essential details being: "(1) A large cylindrical Dewar flask of depth 40 cm. and diameter 10 cm.; (2) a coil of fine copper tubing inside the flask, through which water runs at a uniform rate to take away the heat formed; (3) a thermocouple with its ends in (a) the water going into the flask, and (b) the water coming out of the flask; (4) a galvanometer in another part of the laboratory registering the current through the thermocouple; (5) a Mariotte bottle supplying water at a uniform rate;

(6) a cage of perforated zinc which can be drawn in and out of the flask; (7) tubes for an air supply to the inside."

In operating this calorimeter the temperatures of the water are taken by means of the thermocouple just at its entrance and exit. The observed difference in temperature multiplied by the quantity of water flow per minute gives the heat in calories. The Dewar flask used as a calorimeter chamber is mounted in a box of sawdust, and the water used to take up the heat generated passes around a lead coil outside the flask before passing around the coil inside the flask. "Thus the outside is kept permanently at the temperature of the water which goes in, and it is then found that by this differential arrangement the heat loss is proportional to the actual galvanometer deflection; for 1° C. registered by the galvanometer there is a loss of some 2.9 calories per 1 minute."

Electrical check tests show a very close agreement between the calculated and observed heat production.

### ANIMAL PRODUCTION.

**General review of zoology, I. M. CAULLERY** (*Rev. Gén. Sci.*, 23 (1912), Nos. 9, pp. 353-359; 10, pp. 395-402).—This is a review of the literature published in 1910 and 1911 on heredity, variation, evolution, Mendelism, predetermination of sex, and related topics.

**The mechanistic conception of life, J. LOEB** (*Pop. Sci Mo.*, 80 (1912), No. 1, pp. 5-21).—It is pointed out that the controversy between the vitalists and mechanists is of little importance as regards the progress of biology, but is of vital interest when the results of biological studies are applied to ethical and sociological problems. Recent work has shown that the activation of the egg by the spermatozoa is a chemico-physical process; that individual life begins with the acceleration of the oxidation in the egg, and is not determined by the entrance of a metaphysical life principle; and that the study of heredity is to-day the study of an exact science, and not merely the field of the metaphysician and rhetorician.

These results have been obtained by physico-chemical research, and are cited in support of the mechanistic conception of life, which the author states is the only one compatible with ethics because instincts are based on chemical mechanism.

**The comparative physiology of response in animals, J VON UEXKÜLL** (*Umwelt und Innenwelt der Tiere. Berlin, 1909, pp. 259; rev. in Science, n. ser., 31 (1910), No. 791, pp. 303-305; Nature [London], 83 (1910), No. 2116, pp. 331, 332*).—A summary of studies on the relation of the organism to its environment, which is of interest to the physiologist and psychologist. The topics discussed are the nature of protoplasm, the conversion and differentiation of fluids into organs, and the comparative physiology of reflexes in the lower animals.

**The behavior of chicken sarcoma implanted in the developing embryo, J. B. MURPHY and P. ROUS** (*Jour. Expt. Med.*, 15 (1912), No. 2, pp. 119-132, pls. 6).—Among the conclusions reached are the following: "The direct inoculation of a sarcoma of the fowl into the developing chick embryo or its membranes has yielded growths in many cases. The best results have been obtained with grafts of the living tumor tissue, but, as in the adult, growths can be engendered with dried tissue or with the Berkefeld filtrate of a tumor extract. When living tumor tissue is used, an actual transplantation occurs. . . . Relatively speaking, the embryo seems much more favorable than the adult as a host for the sarcoma."

The structure of reproductive organs of domesticated animals, R. SCHMALTZ (*Die Struktur der Geschlechtsorgane der Haussäugetiere*. Berlin, 1911, pp. XII+388, figs. 168; abs. in *Jour. Roy. Micros. Soc.* [London], 1911, No. 6, p. 743).—A monograph on the generative organs of the horse, ox, sheep, pig, dog, and cat.

The function of the accessory reproductive glands in male mammals, E. IWANOV (*Arch. Mikros. Anat.*, 77 (1911), No. 2, II, pp. 240-248; abs. in *Jour. Roy. Micros. Soc.* [London], 1912, No. 2, p. 167).—The author concludes that the main function of the accessory male reproductive glands is to supply a diluting medium for the spermatozoa. The secretion of the prostate also contains elements which apparently contribute to fermentative processes, and which seem to increase the locomotor energy of the spermatozoa and to shorten their length of life.

The origin of sexual differences, P. KAMMERER (*Fortschr. Naturw. Forsch.*, 5 (1912), pp. 1-240).—A systematic summary and critical discussion of the nature and causes of sex, effect of castration, and related topics.

A bibliography of about 700 references is appended.

Recent work on the determination of sex, L. DONCASTER (*Ann. Rpt. Smithson. Inst.* 1910, pp. 473-485).—A reprint, with additions, of an article noted from another source (*E. S. R.*, 22, p. 273).

Historical-critical studies on hair and hair colors in domesticated animals, with special reference to abnormal whitening. II. WIEGMANN (*Historisch-kritische Studien über Haar- und Hautfarben bei Haustieren mit besonderer Berücksichtigung des Albinismus und Leucismus*. Inaug. Diss., Univ. Bern, 1910, pp. 48).—A review of the literature on the causes of localization of pigment in horses, cattle, sheep, and swine.

Concerning an important kind of hair and the hair coat system of mammals, K. TOLDT, JR. (*Ann. K. K. Naturhist. Hofmus.* [Vienna], 24 (1910), No. 1-2, pp. 195-268, pls. 4, fig. 1).—The morphology, physiology, and distribution of different kinds of hair in mammals are treated in detail. A bibliography is appended.

Comparative anatomy of supernumerary digits in certain ungulates as evidence of the interrelationship existing between the various species, J. SHARE-JONES (*Vet. Jour.*, 67 (1911), Nos. 429, pp. 145-157; 432, pp. 344-355, figs. 10).—A comparative study of abnormal digits in the horse, ox, and pig. The principal structures noted in detail are the bones, tendons, and ligaments.

The continuous origin of certain unit characters as observed by a paleontologist, H. F. OSBORN (*Amer. Nat.*, 46 (1912), Nos. 544, pp. 185-206; 545, pp. 249-278, figs. 8).—The author's studies of the skull and horns of Titanotheres, the horns of cattle, the cranium of man, and the skull and teeth of horses indicate that discontinuity in heredity affords no evidence whatever of discontinuity of origin, and that new characters arise by excessively fine gradations which appear to be continuous. If discontinuities or steps exist they are so minute in these characters as to be indistinguishable from those fluctuations around a mean which seem to accompany every stage in the evolution and ontogeny of unit characters.

"Because the grosser form of Lamarckian interpretation of transmission of acquired characters has apparently been disproved, we must not exclude the possibility of the discovery of finer, more subtle relations between the germ plasma and the soma, as well as the external environment."

The inconstancy of unit characters, W. E. CASTLE (*Amer. Nat.*, 46 (1912), No. 546, pp. 352-362).—In opposition to the views of the genotype and pure line advocates, the author finds that by constant selection in one direction a character may be modified gradually, and cites examples of his own experience in

support of his argument. Thus, a silvered variety of guinea pig was produced by systematic selection from a tri-colored race. The silvered area was gradually increased from an individual which had white hairs interspersed with red on the lower side of the body. In experiments with hooded rats, involving 12 generations and over 10,000 individuals, the pigmented areas were increased in one series and decreased in another by systematic selection. The view is held that the causes of variability are not necessarily located in the chromosome of the cell.

**Mendelian proportions and the increase of recessives**, F. RAMALEY (*Amer. Nat.*, 46 (1912), No. 546, pp. 344-351).—This is a study of stable ratios involving Mendelian dominants, heterozygotes, and recessives as exemplified in the inheritance of left-handedness. The author states that the same results will apply to any recessive character when not selected against in mating. Recessive characters tend to increase in numbers at the expense of original dominant types if not inherently weak in some respect.

“These conclusions are reached from a consideration of the following points: (1) The greater ease with which characters may be lost than gained; (2) the great number of combined dominants and heterozygotes which through mutation may reach a simpler condition as compared with the small number of recessives and heterozygotes which may be imagined as affording opportunity for mutation to dominance; (3) the more likely survival of recessives in an environment of changing conditions in which now the dominant and now the recessive is hard pressed to maintain its existence.”

**Mendel's laws and stock breeding**, J. WILSON (*Hoard's Dairyman*, 42 (1911), No. 47, p. 1442).—An explanation of the principles of Mendelian inheritance so that it can be understood by the stock breeder.

**Mendelism and sex inheritance**, E. RAIL (*Hoard's Dairyman*, 43 (1912), No. 13, p. 502).—A criticism of the article noted above, in which it is maintained that it has not yet been proved that sex is a Mendelian character, and if so would be operative all the time.

**Mendel's law and the occurrence of sex** (*Farm Poultry*, 23 (1912), No. 5, pp. 151, 152).—A discussion of Whitman's work regulating sex in pigeons, as reported by Riddle and of an article by Peck previously noted (*E. S. R.*, 26, p. 773). Concerning the latter the author says: “It fails to account for the male that produces principally females, however mated; and the female that produces principally males. The most conspicuous cases of excess of one sex that I have known or heard of in poultry were cases of males that produced a large excess of females, however mated.”

**Are horns in sheep a sex-limited character?** W. E. CASTLE (*Science*, n. ser., 35 (1912), No. 902, pp. 574, 575).—A criticism of the conclusions in the article of Arkell and Davenport, noted previously (*E. S. R.*, 26, p. 769). The author considers that the assumption of an inhibiting factor is superfluous, as Bateson's hypothesis that the horn character is dominant in males and recessive in females is adequate to explain the results obtained.

**A critical examination of recent studies on color inheritance in horses**, A. H. STURTEVANT (*Jour. Genetics*, 2 (1912), No. 1, pp. 41-51).—A résumé of papers dealing with English Thoroughbreds, Shires, Scotch Clydesdales, French Percherons, and the American Harness horse. The work is summarized as follows:

“It seems probable that chestnut always breeds true. Therefore the placing of chestnut or yellow at the bottom of the scale probably represents the condition of nearly all breeds of horses. Epistatic to it is black. Next comes, in the breeds studied, bay or brown, epistatic to both the preceding. Gray is next higher. Next is roan, which is probably always evident when present (unless

suppressed by the next factor, white), and which probably merely causes a sprinkling of white hairs, without otherwise affecting the color. Finally, we have white."

**Hybridization studies.**—V, **Spermatogenesis in hybrids**, H. POLL (*Arch. Mikros. Anat.*, 77 (1911), No. 2, II, pp. 210-239, pl. 1, figs. 3; *abs. in Jour. Roy. Micros. Soc. [London]*, 1912, No. 2, p. 167).—The author studied the reproductive organs of hybrid ducks (*Cairina moschata* and *Anas boschas*) and of a year-old mule. The tissues of the hybrids were found similar to those of the pure type, except in the development of the reproductive cells.

A bibliography is appended.

**The domesticated animals of ancient Egypt**, P. KUSCHEL (*Die Haustiere Aegyptens in Altertum. Inaug. Diss., Univ. Leipzig, 1911, pp. 45*).—A study of data furnished by inscriptions on monuments and other historical sources concerning the animal husbandry of the ancient Egyptians.

A bibliography is appended.

**The extinct fauna of Crete and its relation to the Minotaur legend**, C. KELLER (*Vrtljschr. Naturf. Gesell. Zürich*, 54 (1909), No. 3-4, pp. 424-435, fig. 1).—From a study of fossils found on the island, the author concludes that *Sus scrofa*, *Cervus elaphus*, *Capra agagrus*, *Bison europaus*, and *Bos primigenius* existed there as wild animals in the time of Minos. Bones of tame swine were found, but are supposed to belong to *Sus indicus*. The palace at Knossos contains works of art, in which *Bos primigenius* is depicted as domesticated and used in bull fighting in premycenaean times. It is suggested that this gave rise to the Minotaur myths.

**Report of the Live Stock Commission, New Jersey**, E. T. GILL ET AL. (*Rpt. Live Stock Com. N. J., 1910-11, pp. 58, pls. 12*).—A summary of the activities of the live stock commission in directing and encouraging breeders in their efforts toward improving the various breeds of live stock found within the State. There is a list of breeders of pure-bred live stock in the State, and a directory of certified stallions now in service.

**Fodders and feeding stuffs**, F. T. SHUTT (*Canada Expt. Farms Rpts. 1911, pp. 181-183*).—An analysis of burnet (*Poterium canadense*) is given as follows: Water 80.24, protein 3.57, fat 0.24, carbohydrates 4.11, fiber 9.75, and ash 1.79 per cent. Analyses are also reported of cotton-seed and linseed meals.

[**Analyses of feeding stuffs**], R. E. ROSE and E. P. GREENE (*Fla. Quart. Bul. Agr. Dept.*, 22 (1912), No. 2, pp. 186-192).—Analyses are reported of cotton-seed meal, dried beet pulp, wheat middlings, molasses feed, and proprietary mixed feeds.

**Feeding stuffs**, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 365-370).—Analyses are reported of cotton-seed cake, coconut cake, bran, sugar beets, acorus, and a mixture of molasses and wood fiber sold under the name of "bastol."

[**Feeding experiments in 1910**], J. H. GRIDALE, R. ROBINSON, J. MURRAY, and G. H. HUTTON (*Canada Expt. Farms Rpts. 1911, pp. 71-76, 76-80, 341, 342, 380-387, 507-509*).—This continues work previously noted (*E. S. R.*, 24, p. 471).

Tests in feeding Angus and Shorthorn steers various proportions of bran, gluten meal, oil-cake meal, clover hay, corn silage, turnips, mangels, and oat straw are reported. Five lots of 20 steers made average daily gains for 290 days ranging from 1.47 to 1.74 lbs., at costs ranging from 4.8 to 8.3 cts. per pound. Subsequently 4 lots of 18 steers made average daily gains for periods of from 62 to 70 days ranging from 1.09 to 2.2 lbs., at costs ranging from 6.66 to 9.44 cts. per pound.

In other tests 64 steers made a gain of 1.64 lbs. per head and day for 165 days at a cost of 9.74 cts. per pound, and 20 steers a daily gain of 1.48 lbs. for 157 days at a cost of 11.25 cts. per pound.

An experiment in sheltering cattle gave the following results for 155 days: With outside feeding the average daily gain per head was 1 lb., at a cost of 18.53 cts. per pound, and the loss per steer was \$1.84. Steers fed inside gained on an average 1.56 lbs. per head and day, at a cost of 7.73 cts. per pound, and returned a surplus over the cost of feeding of \$13.77. It is stated that the small gains made were due to the method of feeding. Oat straw was used for roughage and was not liked by any of the animals.

In a comparison of corn silage and roots for fattening lambs, 3 lots of 9 lambs each were fed 124 days. Lot 1, receiving turnips ad libitum, made average daily gains per head of 0.24 lb. at a cost of 8.8 cts. per pound. The corresponding gains for lot 2, receiving silage ad libitum, and lot 3, receiving both turnips and silage ad libitum, was 0.29 and 0.27 lb., and the cost 7.03 and 7.76 cts. per pound. It is concluded that silage is superior to turnips for fattening lambs, and that it can be profitably used as a part of the roughage ration.

A test of different rations for pigs gave the following gains per head and day for 86 days: Chopped barley 0.9 lb., at a cost of 3.19 cts. per pound; barley and tankage 1.04 lbs., at a cost of 3.72 cts.; peas, oats, and barley 0.85 lb., at a cost of 3.32 cts. per pound; mixed grain and tankage 0.86 lb., at a cost of 4.1 cts. per pound; and mixed chop and tankage 1.23 lbs., at a cost of 4.4 cts. per pound.

**Fattening beef calves in Alabama.** D. T. GRAY and W. F. WARD (*Alabama Col. Sta. Bul.* 158, pp. 175-224c, figs. 17).—The first experiment reported was to determine the cost of finishing 77 high-grade calves for market on different feeds. Three lots from 6 to 8 months old were kept for 4 months on a basal ration of cotton-seed hulls and alfalfa hay. Lot 1, on a supplementary ration of cotton-seed meal, made an average daily gain of 1.71 lbs. at a cost of 6.22 cts. per pound; lot 2, with cotton-seed meal and corn-cob meal in the proportion of 2:1, made an average daily gain of 1.76 lbs., at a cost of 6.19 cts. per pound; lot 3, with cotton-seed meal and corn-cob meal in the proportion of 1:2, made a gain of 1.83 lbs., at a cost of 6.83 cts. per pound. The third lot gave a larger percentage of dressed weight and sold for better price, but not enough more to pay for the extra cost of feed.

To determine if calves can be fattened profitably for the spring market on a feed of cotton-seed meal, cotton-seed hulls, and mixed peavine hay, 52 calves were divided into 2 lots, one lot receiving the shelter of a good barn, and the other fed in the open; but as it was found that the young calves would not thrive during the winter months without shelter the entire lot was placed in sheds. During a period of 112 days the average daily gain for the entire lot was 1.24 lbs., at a cost of 6.97 cts. per pound. Each calf netted a profit of \$3.50.

A test was made in wintering calves and fattening them the following summer on pasture. Thirty-four calves were wintered on cotton-seed meal and hulls, corn chop, and alfalfa hay. The average daily gain for 112 days was 1.13 lbs., at a cost of 8.63 cts. per pound. On March 25 they were turned on good pasture, and in 89 days made an average daily gain per head of 1.33 lbs., at a cost of 4.84 cts. per pound. The profit for each calf was \$1.86.

Among the conclusions drawn are the following: "A farmer may expect to obtain a reasonable profit on beef calves when he raises and fattens them on his farm and sells them when they are 12 to 14 months old. . . . In the South, at least in Alabama at the present time, the calves should be born dur-

ing the early spring months. . . . Young calves can be finished for the market at a profit on cotton-seed meal, cotton-seed hulls, and peavine hay, but it is more profitable to introduce corn-and-cob meal to take the place of part of the cotton-seed meal. . . . The tests seem to indicate that it is more profitable to feed a heavy ration and sell the calves at the end of the winter months, when the prices are normally high, than to hold them until the early summer months."

**Shorthorn herds in Ireland, 1911** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 12 (1912), No. 2, pp. 232-274, pls. 30).—A brief account of the pure-bred Shorthorn herds in Ireland.

**Sinus hairs of the ox**, D. TRETJAKOFF (*Ztschr. Wiss. Zool.*, 97 (1911), No. 2, pp. 314-416, pls. 4; *abs. in Jour. Roy. Micros. Soc.* [London], 1912, No. 1, p. 21).—The author describes the nerve endings in connection with the sinus hairs about the snout, lips, and other parts of the ox. It is thought that the sinus hairs play an important part in the recognition of different kinds of plants.

**Wool**, A. F. BARKER (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 62-85, figs. 1A).—This discusses the quality of wool fiber, yarns, and woolen fabrics, influence of breed and environment on variation in wool fiber, relative values of heavy and light fleeced sheep, and allied topics.

**Pig-feeding experiments**, J. M. SCOTT (*Florida Sta. Rpt.* 1911, pp. XVI-XIX).—In a feeding test involving 5 lots of 5 pigs each, and lasting 60 days, the total gains for each lot were as follows: On velvet beans in the pod, 25 lbs.; velvet beans in the pod and Japanese cane 1:1, 4.3 lbs.; velvet beans in the pod and Japanese cane 2:1, —7.7 lbs.; Japanese cane alone, 61 lbs.; and velvet beans in the pod and sweet potatoes 1:1, 12.3 lbs.

In a feeding test which lasted 90 days and with 5 pigs in each lot, those given shelled corn made an average gain per head and day of 0.26 lb., at a cost of 8.19 cts. per pound; shelled corn and culled velvet beans 1:1 by weight 0.17 lb., at a cost of 9.96 cts. per pound; shelled corn, culled velvet beans, and shorts 1:1:1, 0.26 lb., at a cost of 8.98 cts. per pound; and shelled corn and culled velvet beans 1:1, and all the green sorghum they would eat, 0.24 lb., at a cost of 7.96 cts. per pound.

Seventeen pigs 3 months of age, when put on a ration of corn, shorts, milk, and green sorghum, made in 30 days an average daily gain per head of 0.96 lb.

**The pig industry**, R. T. ARCHER (*Jour. Dept. Agr. Victoria*, 10 (1912), Nos. 2, pp. 73-82; 3, pp. 160-169; 4, pp. 239-255, figs. 27).—This contains information on breeds of pigs, cooperative bacon factories, the international trade in pork products, and statistical data on the pig industry.

**Studies on conformation, function, and pilosity in horses**, W. KRYNITZ, H. MAGERL, and A. RAST (*Arb. Deut. Gesell. Züchtungsk.*, 1911, No. 11, pp. 208, figs. 4).—This contains 3 articles. The first two, by Krynitz and Magerl, discuss the correlation between form and function of the different types of horses. A large number of measurements are submitted, and both authors think that the adaptability of the horse to slow or fast work can be predicted with a reasonable degree of accuracy by making measurements. The third article, by Rast, is a study of the characters of the hair and hair whorls as an aid in judging horses.

Bibliographies are appended.

**Feed, care, and management of breeding stallions, brood mares, work horses and young foals**, F. C. MINKLER (*Live Stock Com. N. J. Circ.* 2, 1912, pp. 30, pls. 3).—This contains general information of interest to horse breeders, a list of stallions now in service, and a copy of the state stallion law.

**The horse-breeding industry in Yorkshire**, H. E. FAWCUS (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 85-116).—A historical account of the types of horses which have been bred in Yorkshire, including a general discussion of the condition of the horse-breeding industry.

**Report of the poultry manager**, A. G. GILBERT (*Canada Expt. Farms Rpts. 1911*, pp. 277-294, pl. 1).—This contains statistics on prices and production of poultry, discusses the grading of poultry and eggs and the sale of poultry products through cooperative societies, and reports experimental work at the station.

As regards fertility of eggs there seemed to be no advantage in limiting the males to a small number of hens. The percentage of eggs hatched by hens was larger than that hatched by incubator. On a free range the chickens gained 1.15 lbs. each in 2 months, while on a limited run the gain was 2.45 lbs. Experiments by F. T. Shutt in the preservation of eggs indicated that lime-water is superior to water glass as a preservative.

**Housing farm poultry**, A. G. PHILIPS (*Indiana Sta. Circ. 37*, pp. 16, figs. 21).—A trap nest, oat sprouter, and several poultry houses are illustrated and described.

**Egg records for the year 1910-11** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 12 (1912), No. 2, pp. 374-387).—This contains egg records of 153 flocks of fowl.

**The important subject of eggs**, G. B. MORSE (*Recl. Poultry Jour.*, 19 (1912), Nos. 3, pp. 493, 494, 525-528; 4, pp. 656, 657, 685-688).—This article reviews investigations on the bacteriology of the hen's egg. Summing up the work, the author states that fresh eggs laid by healthy virgin pullets are generally free from bacteria, whereas hens that have been mated or that have diseased ovaries lay eggs which are liable to be infected. The source of external infection and the transmission of disease to man and other fowls from infected eggs are discussed. Different methods of preserving eggs are described.

**Preservation of eggs by freezing**, F. LESCARDÉ (*Ber. II. Internat. Kälttekong. Wien*, 2 (1910), pp. 373, 374).—This is a report of a successful attempt to preserve eggs for 13 months by subjecting them to low temperatures.

**Raising Belgian hares and other rabbits**, D. E. LANTZ (*U. S. Dept. Agr., Farmers' Bul. 496*, pp. 16, figs. 5).—This contains instructions both for those who wish to raise rabbits or hares chiefly for home consumption, and for those who desire to raise them for market. It discusses the history and characteristics of Belgian hares, selection of stock, hutches and pens, food and feeding, breeding, marketing, and ailments of rabbits.

**Pond culture problems** (*Wiener Landw. Ztg.*, 62 (1912), No. 11, pp. 123-125, fig. 1).—The cleaning, liming, and general management of fish ponds are discussed, and a number of books and articles on the subject are reviewed.

## DAIRY FARMING—DAIRYING.

**The feeding problem**, J. B. LASSEN (*Tidsskr. Landökonomi*, 1912, No. 5, pp. 321-348).—An address discussing the various methods of determining the feed requirements of dairy cows, and the application of the feed unit system in the bookkeeping on Danish dairy farms.

**Experiment with sugar-beet slices (schnitzel) as a food for milch cows**, D. TURNER and C. D. STEWART (*Agr. Students' Gaz.*, n. ser., 15 (1912), No. 6, pp. 185-188).—In experiments with 6 cows, where the basal ration consisted of straw chaff, hay, Bombay cotton-seed cake, soy cake, gram, and molascuit, mangolds proved to be a better feed than sugar-beet chips. The butter from the lot fed on sugar-beet chips was hard, more difficult to work, and had to

be churned at a higher temperature, but the color of the butter was much better than that from the lot fed mangolds. The beet chips seemed to have a laxative effect at first, and the cows in that lot showed greater signs of thirst than those on the mangolds. Some little time was also necessary for the cows to become accustomed to the beet-chip ration.

**Dairy cattle, J. H. GRISDALE** (*Canada Expt. Farms Rpts. 1911, pp. 59-71*).—This describes the methods of feeding the station herd, methods of making cream cheese and Coulommier cheese, and contains the records of individual cows.

**Winter dairying and creameries** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 12 (1912), No. 2, pp. 281-303).—This contains data on milk and butter production in Ireland.

**Dairying in Denmark, 1911, B. BÖGGILD** (*Tidsskr. Landökonomi, 1912, No. 4, pp. 257-276*).—This is the customary report on the conditions of Danish dairying during the year, with statistics relating to the dairying industry.

**Report of the Austrian dairy committee on the condition of the dairy industry in the different crown lands, REINISCH ET AL.** (*Österr. Milk. Ztg.*, 18 (1911), Nos. 11, p. 163; 13, pp. 195, 196; 18, pp. 275, 276; 23, pp. 356, 357; 24, pp. 371, 372; 19 (1912), Nos. 1, pp. 3-5; 3, pp. 37, 38; 4, pp. 50-52; 5, p. 66; 7, pp. 99, 100; 8, pp. 115-117; 9, pp. 132, 133; 10, pp. 147, 148; 11, pp. 163-165).—This contains statistical data reported by different authors on the methods of management, milk production, and related topics in Vorarlberg, Kärnten, Salzburg, Steiermark, Lower Austria, Upper Austria, Moravia, Galicia, Silesia, Carniola, and Bohemia.

**Cow mortality tables** (*Hoard's Dairyman*, 43 (1912), No. 18, pp. 689, 690).—An attempt to estimate the average length of life of a dairy cow, based on data contained in the Holstein-Friesian herd books.

**The inheritance of milk yield in cattle, J. WILSON** (*Sci. Proc. Roy. Dublin Soc., n. ser.*, 13 (1911), No. 7, pp. 89-113).—Records of Danish cows are submitted as a proof that improvement in milk yield by breeding is not a gradual process, as has been supposed, but is inherited in Mendelian fashion, that is, if a daughter is not on an approximate equality with her dam as a milk producer she is either much higher or much lower. The extreme grades are the parent strains, and the intermediate are the hybrids. Records of progeny of a few bulls are also given to bear out the same argument.

**The "escutcheon:" A guide to milking merit, J. S. McFADZEAN** (*Jour. Dept. Agr. Victoria*, 9 (1911), No. 9, pp. 585-599, figs. 23).—This is an attempt to revive an old theory as advocated by Guenon. The different types of escutcheon are illustrated and described.

**Testing the dairy cow, T. R. MIDDLETON** (*Ohio Sta. Circ. 122, pp. 121-134, figs. 13*).—This contains advice in regard to keeping records of dairy cows, and gives directions for the use of the Babcock test with milk and skim milk.

**Secretion in the mammary gland, H. HOVEN** (*Anat. Anz.*, 39 (1911), No. 11-12, pp. 321-326, figs. 4; *abs. in Jour. Roy. Micros. Soc. [London]*, 1912, No. 2, p. 171).—At the beginning of secretion in guinea pigs the cytoplasm of the cells contains numerous chondriosomes, forming long undulating filaments. These break into granules, some of which are transformed into secretory granules (probably becoming casein or sugar), while others are transformed into minute drops of fat.

**Milk, G. B. TAYLOR** (*Bien. Rpt. La. Bd. Health, 1910-11, pp. 82-107*).—Analyses and bacterial counts of milk, and other results of milk inspection, are reported.

**A biometrical study of milk streptococci, J. BROADHURST** (*Jour. Infect. Diseases*, 10 (1912), No. 3, pp. 272-284, figs. 4).—A study of the fermentative

reactions of different species of streptococci found in milk. The results are summarized as follows:

"Morphological characters are not correlated with fermentative powers. Milk and neutral red are not sufficiently diagnostic to aid in determining the sources of streptococci. Lactose, saccharose, salicin, raffinose, mannit, and inulin seem to have significant fermentative reactions. Saccharose, salicin, and inulin should be tested with human, bovine, and equine streptococci. The milk streptococci form a large number of groups when classified with regard to their effect upon the six test substances. The milk streptococci are characterized by unusually high fermentative powers. The incomplete data at hand indicate that the milk strains are most like the human strains; there is less likeness between the milk and the bovine strains; they show practically no resemblance to the equine strains.

"It is proposed to continue this quantitative comparison of fecal (human, bovine, and equine) and milk streptococci in these and other media, in the hope that complete quantitative comparisons will give a method of determining the source of streptococcal pollution of milk."

Silicates in milk from glass bottles. H. SCHULZ (*München. Med. Wehnschr.*, 59 (1912), No. 7, pp. 353, 354; *abs. in Clean Milk Bul.*, 1 (1912), No. 5, p. 107).—These experiments consisted of boiling modified milk in bottles of various kinds from 5 to 15 minutes. There was an increase of silicic acid in milk which had been sterilized in cheap bottles, while milk boiled in bottles made of better glass contained only a trifling amount. Momentary boiling in cheap bottles showed no acid.

Investigations on dairy bacteriology. WEIGMANN and A. WOLFF (*Milchw. Zentbl.*, 41 (1912), Nos. 1, pp. 2-6; 3, pp. 65-68; 4, pp. 97-100; 5, pp. 129-134).—A report of experiments in isolating several organisms which were found to cause a bitter taste, premature coagulation, and other abnormal qualities in milk.

A milk-borne epidemic of typhoid fever. E. B. BIGELOW (*Jour. Amer. Med. Assoc.*, 57 (1911), No. 18, pp. 1418-1420).—A brief report in which the sources of outbreaks of several cases of typhoid epidemics were located by testing for the Widal reaction samples of blood from every person connected with the suspected dairies. It is maintained that the disease could be nearly eliminated if typhoid carriers were sorted out by testing specimens of blood from all persons living on dairy farms or handling food consumed without heating, and prohibiting those reacting from engaging in such occupations.

Sanitary improvement of milk supply. E. C. LEVY and T. J. STRAUCH (*Ann. Rpt. Health Dept. Richmond, Va.*, 1911, pp. 45-59, 140-143, figs. 2).—This contains a report of the work relating to milk inspection, which shows a great improvement in the quality of milk and sanitary surroundings of dairies since the inspection was begun in 1907.

[Refrigeration in the dairy industry] (*Ber. II. Internat. Kältkong. Wien*, 2 (1910), pp. 353-367, 400-430, figs. 7).—These papers were read at the second International Refrigeration Congress, held at Vienna, October, 1910.

*The effect of cold storage upon the bacteriological and chemical changes in milk and butter*, C. E. Marshall (pp. 353-367).—This is a semipopular review of investigations at the state experiment stations in the United States and by the Dairy Division of this Department. The work is summarized as follows: "Milk and butter must be frozen to check completely the growth of microorganisms. Enzymic action probably is not completely inhibited by low temperatures and freezing, or, in other words, there may be deterioration in milk and butter even when frozen. The effect of lower temperatures than these cited herein is not determined."

*The application of low temperatures to the curing and storage of Cheddar cheese*, S. M. Babcock (pp. 400-414).—This is a historical résumé of investigations of refrigeration which have been of practical value in manufacturing Cheddar cheese.

*Employment of refrigeration in the cheese industry*, P. Guerault (pp. 415-422).—A résumé of some European methods.

*The application of refrigeration in the manufacture of Roquefort cheese in Arcyron*, P. Lebrun (pp. 423-430).—The details of making Roquefort cheese are described, with special reference to the influence of temperature as affecting the quality of the cheese.

*Cost of making [butter]*, F. BALLANTYNE ET AL. (*N. Y. Produce Rev. and Amer. Cream.*, 3½ (1912), No. 3, pp. 90-92).—These are estimates of practical butter makers on the cost of making butter. The figures submitted range from 1.42 to 3 cts. per pound.

*Cost of making [cheese]*, F. BALLANTYNE ET AL. (*N. Y. Produce Rev. and Amer. Cream.*, 3½ (1912), No. 3, pp. 110, 111).—This consists of statements of practical cheese makers, showing that the cost varied from 55 cts. to \$2.50 per 100 lbs. The two principal factors which influence the cost of making are the time of year and the amount of cheese made.

*The manufacture of "gray" cheese in the Tyrol*, J. HUSSMANN (*Milchw. Zentbl.*, 41 (1912), Nos. 2, pp. 55-58; 3, pp. 86-90).—A discussion of the management of dairy farms in the Tyrol, and the methods of making a skim milk cheese known in that region as "gray" cheese.

*How to make "Jack" cheese*, E. H. HAGEMANN (*Pacific Dairy Rev.*, 16 (1912), No. 12, pp. 3, 4; *N. Y. Produce and Amer. Cream.*, 3½ (1912), No. 2, pp. 66, 67).—Details of making "Jack," formerly called Monterey, cheese are given.

*A coating for cheese*, A. PRESTADIUS (*Nord. Mejeri Tidn.*, 27 (1912), No. 14, p. 159; *abs. in N. Y. Produce Rev. and Amer. Cream.*, 3½ (1912), No. 2, pp. 54, 55).—This is a recipe for making a new preparation for coating half-soft cheeses of the Stilton and Gorgonzola type, and which consists of vaseline, plaster of Paris, gum arabic, and salt. The vaseline is used to give it the consistency of butter, the gum arabic to make the paste pliable and adhesive, and the salt to keep it moist and soft. Vaseline and plaster of Paris, when used without the salt and gum arabic, dried up and fell to powder.

*Concerning buttermilk and its derivatives*, F. LEPERRE (*Handel. Vlaamsch Natuur en Geneesk. Cong.*, 15 (1911), pp. 49-52).—Analyses of buttermilk and whey are reported.

## VETERINARY MEDICINE.

*Springtime surgery*, edited by D. M. CAMPELL (*Chicago*, 1912, pp. 143).—This is a collection of articles which have appeared from time to time in the *American Journal of Veterinary Medicine*, and which deal chiefly with those surgical procedures which are employed in the spring of the year.

*Biological products*, C. H. HIGGINS (*Amer. Vet. Rev.*, 41 (1912), No. 3, pp. 282-289).—This is a general discussion of the evolution of biological therapy. The methods of combating disease in Canada by means of serums, vaccines, etc., are described.

*Report from the government veterinary surgeon for the year 1910-11*, J. A. RALEIGH (*Rpt. Dept. Sci. and Agr. Brit. Guiana*, 1910-11, pp. 69-71).—A brief account of the work of the year.

*Report of the department of animal hygiene of the Emperor William Institute for Agriculture at Bromberg*, MIESSNER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 3 (1911), No. 1, pp. 30-41).—This is a report of the activities of this division from 1906 to 1909, inclusive. It deals with the

results obtained with sero-diagnoses of glanders, combating tuberculosis, ag-gressin tests, preparation of vaccine against hemoglobinuria in bovines, toxicity of castor-oil seeds, septicemia pluriformis ovium, combating hemoglobinuria in bovines, beschälseuche, feeding tests (with eosin, beans, and sea fish), anaphylaxis investigations, paratyphoid investigations, chemotherapeutic tests with hemoglobinuria of bovines, and examination of the samples sent to the station.

**Animal diseases in Formosa, J. D. REARDON** (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 3, pp. 144-146).—It is stated that while the Prefecture of Ako, which is about 42 square miles in area, has always been more or less infested with rinderpest, on July 10, 1911, the disease broke out in a very virulent form, 2,100 cases having been diagnosed since that date.

Investigations in regard to the receptivity of fowls for anthrax, and the reason for their resistance against this disease, W. MÖLLHOFF (*Untersuchungen über die Empfänglichkeit des Geflügels für Milzbrand und über die Gründe der Resistenz des Huhnes gegen diese Krankheit. Inaug. Diss., Univ. Bern, 1910, pp. 47; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 49 (1911), No. 6, p. 162*).—The resistance of the fowl against anthrax is considered due to the presence of bactericidal substances in the lymph or other body fluids of this animal. When anthrax bacilli are placed into the subcuticular tissue they die in a very short time, and in this way prevent a local development of the anthrax organism and protect against a generalized infection. The origin of the bactericidal substances in the lymph could not be determined. Phagocytosis seems to have no significance for this disease in fowls. The resistance of the fowl to the disease is not due to its high body temperature.

The thermoprecipitation method for diagnosing anthrax, A. CASALOTTI (*Berlin. Tierärztl. Wehnschr.*, 27 (1911), No. 49, pp. 889, 890).—The thermo-precipitation test is considered a good one for diagnosing anthrax.

The Ascoli precipitin reaction for diagnosing anthrax, L. GRANUCCI (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 10 (1911), No. 6, pp. 454-470; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 1, pp. 867, 868).—The specific precipitinogen was found to develop first at the site (or path) where the virus was injected, and the amount increases as the disease progresses. It is also dependent on the number of virulent organisms present, and the affinity which the organisms have for the virus. If the bacilli are present only sparingly the precipitinogen must be looked for at the area of the body which was first attacked by the organisms. The precipitinogen will withstand a temperature of 100° C. for several minutes. It is not destroyed by putrefaction nor by allowing it to dry for a year, and not in an organ which has been preserved in alcohol for 11 years or longer. Formalin changes or destroys the precipitinogen.

The specificity of Ascoli's precipitin reaction when utilizing various organs for the diagnosis, G. RONCAGLIO (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 9 (1911), No. 6, pp. 424-432; *Clin. Vet. [Milan], Russ. Pol. Sanit. e Ig.*, 34 (1911), No. 10, pp. 450-458; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 4 (1911), No. 8, pp. 405, 406).—The Ascoli reaction (E. S. R., 26, p. 375) was found positive only when anthrax was present. It made very little difference whether the organs used were in a state of decomposition or fresh. The most characteristic reaction was obtained with extracts from the spleen, but the other organs, etc., also gave good results. They behaved as regards specificity in the following order: The gelatinous mass (edema) in the skin (which surrounds the injection areas of guinea pigs treated with anthrax bacilli), the heart, lungs, blood, muscle, liver, kidneys, and brain substance.

Recent investigations on the etiology of foot-and-mouth disease, J. SIEGEL (*Vet. Jour.*, 68 (1912), Nos. 440, pp. 77-82; 441, pp. 155-159).—This is a trans-

lation of a paper presented before an assembly of Prussian government veterinarians in November, 1911, relative to investigations of the causative organism of foot-and-mouth disease (*Cytorrhycetes aphtharum*). See also previous notes (E. S. R., 26, pp. 376, 682).

**Foot-and-mouth disease in the Netherlands in 1911**, H. REMMELTS (*Dept. Landb., Nijv. en Handel, Verslag. en Medcd. Dir. Landb. [Netherlands], 1912, No. 1, pp. 178, pls. 11, figs. 5*).—This is a detailed report on foot-and-mouth disease, of which 70,518 cases were reported during the year 1911.

The catalase contained in the milk of cows suffering from foot-and-mouth disease, H. BERTIN-SANS and E. GAUJOUX (*Hyg. Viande et Lait, 6 (1912), No. 4, pp. 193-197*).—The catalytic activity of milk obtained from animals affected with foot-and-mouth disease is increased during the first stages of the disease, but as the disease progresses catalysis becomes less and finally it turns to the normal level.

**Foot-and-mouth disease in horses**, D. A. DE JONG (*Tijdschr. Veeartsnijck., 38 (1911), No. 18, pp. 689, 690; abs. in Vet. Rec., 24 (1912), No. 1232, p. 514*).—While it is known that horses are somewhat susceptible to foot-and-mouth disease, cases of its transmission to them are very rare. In this paper the author records an instance of its occurrence in 3 foals, which had been weaned a few days previous to July 15, on which date they were placed in a field occupied by cattle suffering from the disease. Five days after the foals were placed in the field the first symptoms of the disease, namely, difficult prehension of food and salivation, appeared. The buccal mucous membrane showed aphthæ—some intact and others burst—at different points.

On June 30 one of the foals still showed salivation, and traces of vesicles were still clearly apparent upon the tongue and in other portions of the mucous membrane, but lesions upon other parts of the body, notably upon the feet, did not exist. These cases are thought to prove that it is insufficient in dealing with foot-and-mouth disease to confine preventive measures to ruminants and pigs.

**Hoffmann's method against foot-and-mouth disease**, LUCAS (*Deut. Tierärztl. Wchenschr., 20 (1912), No. 11, pp. 162-165*).—Euguforn, which is a chemical compound prepared from formaldehyde and guaiacol, was found to be a very efficient product for treating foot-and-mouth disease externally.

**Immunizing horses against glanders with killed glanders bacilli (farase)**, A. DEDIULIN (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 9 (1911), No. 6, pp. 382-391; abs. in Berlin. Tierärztl. Wchenschr., 28 (1912), No. 11, pp. 195, 196*).—On an estate, which during harvest time works 10,000 horses, 276 succumbed to glanders. In order to determine if horses could be immunized against the disease 303 out of a group of 600 animals were treated with "farase" (E. S. R., 19, p. 887). One year and four months after the inoculation 14 of the non-immunized animals became glanderous. No cases of glanders were noted among the vaccinated horses with the mallein test, although they had been in direct contact with the unvaccinated animals throughout the entire period.

**In regard to the cause and the diagnosis of Malta fever**, K. SAISAWA (*Ztschr. Hyg. u. Infektionskrank., 70 (1912), No. 2, pp. 177-203; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 5 (1912), No. 3, pp. 12, 13*).—The following conclusions were drawn:

(1) The causative agent of Malta fever is a bacterium which appears in the form of a short rod. The name *Bacterium melitense* is therefore to be given in preference to *Micrococcus melitensis*. (2) The bacteria grow in dextrose solutions, but best on alkaline media. (3) The bacteria possess a certain pathogenicity for rabbits and guinea pigs, the disease running the course of an acute sepsis. (4) In healthy animal and human sera. as well as sera which origi-

nate from cases of other diseases—that is, by normal agglutinins—the Malta fever bacteria are agglutinated, although their behavior toward normal agglutination depends largely upon the strain employed and the individual composition of the sera having variant agglutinability. (5) With rabbit and goat immune sera and in the sera obtained from Malta fever subjects the agglutinability of the various strains tested was very uniform. (6) The agglutinins of normal serum were inactivated by heating serum for one-half hour at 55° C., while the immune-agglutinins remained stable at this temperature. It is therefore recommended that for diagnostic purposes the serum obtained from an affected subject be heated for one-half hour at 55° C. before conducting the test. (7) With watery extracts of Malta fever bacteria a specific complement-fixing substance can be demonstrated in the serum with the aid of the complement-fixation test. (8) The opsonic index for Malta fever bacteria in the serum was in one of the cases increased.

**Contribution to the diagnosis of Malta fever, J. R. MOHLER and A. EICHHORN** (*Jour. Amer. Med. Assoc.*, 58 (1912), No. 15, pp. 1107-1109).—This includes a discussion of the history of Malta fever, its discovery in Texas (E. S. R., 25, p. 782), the various methods of diagnosis, and the experiments of the authors as regards the complement fixation test.

Owing to the differences of opinions which exist in regard to the agglutination test used for diagnosing this condition, the authors sought to determine the utility of the complement fixation test for this purpose. "From the results of these investigations it appears that the complement fixation test can be utilized for the diagnosis of Malta fever, and in consideration of the fact that the agglutination test is not always reliable for such purposes, the complement fixation would be of great advantage as an adjunct in the diagnosis of this malady."

A description of the complement fixation and macroscopic agglutination tests as utilized by the authors is given in detail.

**Rinderpest as observed in the Philippines, W. SORRELL** (*Amer. Vet. Rev.*, 41 (1912), No. 3, pp. 290-299, figs. 3).—This is a description of the disease as it is encountered in the Philippine Islands, and a discussion of the various methods utilized for combating it.

**A cultural method of hyperimmunizing animals for the production of anti-rinderpest serum, F. S. H. BALDREY** (*Jour. Trop. Vet. Sci.*, 6 (1911), No. 3, pp. 251-256).—This work shows "that anti-rinderpest serum can be prepared by the inoculation of virulent blood diluted with broth. It appears possible that an active toxin is produced and excreted into the broth by the rinderpest organisms contained in the virulent blood and by this means the results recorded are obtained. This material or probable toxin is rapidly excreted and so active that it appears to quickly inhibit any further growth of the rinderpest organism, destroying its virulence and finally killing it.

"The substance so obtained is very much more active than that obtained in virulent blood, so much so that it can not be given subcutaneously with safety on account of the extreme inflammatory condition it sets up. To use it as an hyperimmunizing agent, doses are better given intravenously and gradually increased so that the [injections are] spread over a period of some 2 months or more. The immune serum so obtained is powerful, but 15 to 20 per cent weaker than that made by massive injections of virulent blood. The method is an eminently practical one and shows a great financial saving."

**Tests of anti-rinderpest serum, A. R. WARD and F. W. WOOD** (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 2, pp. 75-79).—"The experiments seem to show that anti-rinderpest serum does not prevent infection with rinderpest. On the contrary, animals injected with serum and exposed to rinderpest soon

contract the disease and pass through a more or less modified attack. [It is shown that the blood of animals is infective during this attack.]

The authors point out the inadvisability of relying upon serum to prevent an attack of this disease. Such serum has been advocated by sanitarians in various parts of Africa.

Investigations in regard to tetanus curative sera prepared according to various methods with the aid of immunity reactions and animal tests. W. SCHÜRMAN and E. SONNTAG (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 12 (1911), No. 1, pp. 1-15; abs. in *Zentbl. Biochem. u. Biophys.*, 12 (1912), No. 23, p. 932).—Treating horses by subcutaneous injections of toxins, i. e., bacilli and spores, yields no agglutinins or precipitins specific for the tetanus bacillus in the blood serum. The serum obtained in protective tests with animals pre-treated with toxin behaved in the same manner. The protective action probably runs parallel with the antitoxin content of the serum. By giving killed or living bacteria intravenously to a rabbit a slight agglutinin, with a marked precipitin formation, took place.

The treatment of tetanus by magnesium sulphate, carbolic acid, and anti-tetanus serum. J. CAMUS (*Compt. Rend. Soc. Biol. [Paris]*, 72 (1912), No. 3, pp. 109-112; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 3, p. 11).—Magnesium sulphate and carbolic acid were found of no value in treating tetanus, the former having only a momentary effect upon the spasm. The serum treatment of tetanus is far better. Some tests with an antitoxic serum prepared with peysin are also reported but the results obtained were very uncertain.

Bovine and human tuberculosis, LYDIA RABINOWITSCH (*Berlin. Klin. Wchenschr.*, 49 (1912), No. 16, pp. 752-754).—It is stated that the bovine type of bacillus causes a great many cases of tuberculosis in man. Prophylaxis must therefore not be ignored in this direction.

Tuberculosis in chickens, Y. VOSGIEN (*Hyg. Viande et Lait*, 6 (1912), No. 4, pp. 207-211).—Out of 226 chickens which were seized as being tuberculous 145 on autopsy showed lesions of tuberculosis. The tuberculous processes were distributed among the following organs: Liver, 143 cases; spleen, 135; cervical ganglion, 102; lungs, 61 (1 case of tuberculosis of lungs and trachea included); bones and articulations, 46; alimentary canal, 30; peritoneum, 13; kidneys, 9; and ovaries, 6 cases.

Tuberculosis of poultry. RAYMOND and CHRÉTIEN (*Hyg. Viande et Lait*, 6 (1912), No. 4, pp. 211-226, figs. 8).—This article includes observations made in regard to the occurrence of tuberculosis in poultry as noted at the central game market at Paris. The article is illustrated with drawings of pathological preparations. The distribution and frequency of the lesions are stated and discussed.

The tuberculin test, P. FISCHER (*Proc. Amer. Vet. Med. Assoc.*, 48 (1911), pp. 536-556).—A discussion of the nature of the tuberculin test and a detailed statement of the results obtained with it in the State of Ohio.

In regard to tuberculin anaphylaxis and its relation to the tuberculin reaction, T. J. VON CAPELLE (*Zentbl. Bakt. [etc.]*, I, Abt., Orig., 60 (1911), No. 6, pp. 531-542).—Anaphylaxis can be produced with tuberculin because the tuberculo-protein contains an integrating substance upon which anaphylaxis depends. According to this the tuberculin reaction is an anaphylactic process. Anaphylaxis so produced can be conveyed from one animal to the other.

Upon the defense of the organism against infection by the tubercle bacillus, A. CALMETTE and C. GUÉRIN (*Ann. Inst. Pasteur*, 25 (1911), No. 9, pp. 625-641).—The serum of bovines which were hyperimmunized by repeated injections of modified (in media of ox bile) tubercle bacilli, when injected into guinea pigs, will not prevent or cure tuberculosis in these animals. When given with

attenuated or virulent bacteria it stimulates a rapid evolution of the pathological lesions in the animals. If the serum is used in large doses it may retard the pathological process, but on the other hand it will have a tendency to favor the elimination of tubercle bacilli through the regular excretory channel.

**The intradermal tuberculin test,** D. F. LUCKEY (*Amer. Vet. Rev.*, 41 (1912), No. 3, pp. 316-323).—The intradermal test in the hands of this author gave good results, in fact, results somewhat better than those obtained by the old subcutaneous method. The method of making the test is described. The author also points out the value of keeping a history of the animals in the vicinity.

**Diagnosis of pulmonary tuberculosis with regard to the new sanitary laws,** O. MÜLLER (*Berlin. Tierärztl. Wchschr.*, 28 (1912), No. 17, pp. 293-295, figs. 2).—This is a description of the Königsberg method devised by Müller, Jonske, and Wiemann for diagnosing tuberculosis. This is a modification of the method of Scharr and Opalka (*E. S. R.*, 26, p. 679), but is supposed to possess certain advantages which are described in detail. The author recommends giving an injection of cocaine at the point where the cannula is to be inserted 15 minutes before the operation. Reasons for not using the Rautmann and the Tallgren and Graae apparatus are given.

**Sputum gathering methods for diagnosing tuberculosis in bovines,** H. RAUTMANN (*Berlin. Tierärztl. Wchschr.*, 28 (1912), No. 19, pp. 335-337).—This is a polemic in regard to Müller's method (see above) for obtaining sputum. The author also discusses the value of his own apparatus, which is a modification of the Tallgren and Graae apparatus (*E. S. R.*, 24, p. 84).

**Preliminary report upon the injection of rabbits with protein-free (tuberculo) antigen and antigen-serum mixture,** A. H. CAULFIELD (*Proc. Roy. Soc. [London]*, Ser. B, 84 (1911), No. B 573, pp. 390-394).—This work is summarized as follows:

"The injection of rabbits with a saline dilution of an alcohol-ether extract of tubercle bacilli is capable of producing complement-fixation bodies to that antigen. The digestion at 37.5° C. of the alcohol-ether extract with inhibitive serum (human) for various intervals up to 1 hour does not affect the production of the specific sensitizers. The digestion at 37.5° of the alcohol-ether extract with fixation-positive serum (rabbit) for 1 hour inhibits the production of specific sensitizers. . . .

"The injection of 'bacillen-emulsion' in 2, 1.5, 0.5, and 0.005 mg. amounts failed to induce fixation bodies. The injection of 100 mg. of partially dried dead tubercle bacilli (after alcohol-ether extraction) produced after the first injection sensitizers, so that 0.1 cc. serum caused complete fixation although the injection of 0.5 mg. failed to do this. . . .

"The rabbit's blood was obtained by puncture of the ear vein and withdrawal by a 2 cc. record syringe. This has been found to be the most rapid and satisfactory method of obtaining up to 5 cc. of blood. The needle and syringe are sterilized in hot oil, the needle being then well cleared in cold sterile saline."

**The results obtained in the eradication of tuberculosis from a herd by the use of tuberculosis vaccine and the Bang system,** S. H. GILLILAND (*Ann. Rpt. Penn. Dept. Agr.*, 16 (1910), pp. 166-179; *Proc. Amer. Vet. Med. Assoc.*, 48 (1911), pp. 477-492).—This is the report of a series of experiments made for the purpose of eradicating tuberculosis from a herd, which originally consisted of 200 animals, comprising Holsteins, Guernseys, and grades, on the basis of the tuberculin test and the Bang method.

In 1904, when the tests were begun, 160 animals, which constituted the milking herd, were tested and showed 42 reactors, or 26.2 per cent. Nearly all of the reacting animals were in various periods of gestation and kept in separate

barns for the purpose of obtaining their offspring. The main milking herd was then distributed among four separate disinfected barns, which held from 12 to 48 animals each. In the majority of cases the milking animals were tested every 6 months until 2 negative tests were obtained and then yearly thereafter. Calves intended for future introduction into the milking herd were immunized with human tubercle bacilli intravenously injected. All new cows purchased were placed in quarantine 150 ft. from the main barns.

In the spring of 1905 the milking herd, which then consisted of 120 animals, was again tested and showed 13, or 10.8 per cent, of reactors. Five months later (November, 1905), out of 136 animals 7, or 5.1 per cent, reacted. In April, 1906, 150 animals were tested and of these 13, or 8.4 per cent, reacted, and in the following November out of 137 animals tested 5, or 3.6 per cent, gave the test. In April, 1907, 201 animals and in October of the same year 137 animals were tested, but no reactions were found. During 1908, in the months of April and November, 145 and 169 animals, respectively, were examined. In the first case the reactors present amounted to 1.4 per cent and in the latter to 1.8 per cent, which shows a reinfection of the herd. In April, 1909, no reactors were present in the herd, but about a year after this, out of a herd of 151 animals, 5 animals or 3.7 per cent reacted. The author accounts for the reinfection of the herd the second time as due to the fact that 2 valuable animals which reacted in November, 1908, were retained in the herd for a retest. "The history and cycle of the tuberculin test for these 2 animals and a few others are dealt with in detail in the original.

"[In the vaccination experiments which were conducted] since 1904 there were 184 calves vaccinated, of which 46 are in the main milking herd at the present time. Of the 143 animals that were sold for breeding purposes, for beef, or that died from lung worms, etc., post-mortem examinations were obtained on approximately 100 head and no lesions of tuberculosis were found in any except those aforementioned following the tuberculin test of 1911."

The vaccine used was made from the human type of tubercle bacillus, which was never more than 36 hours old.

**Report on an experiment to produce a tolerance in cows to tubercle bacilli after injection of various products.** A. J. SMITH and H. FOX (*Ann. Rpt. Comr. Health Penn., 4 (1909), pt. 1, pp. 251-268*).—In these experiments 3 definitely tubercular cows, 2 which were highly suspicious, and 2 which were almost certainly free from the disease were used. The latter 2 animals served as controls, and one received no vaccine. All of the rest of the animals were given a pretreatment with tubercle bacilli in order to determine their degree of resistance toward the products. The products injected, either under the skin or intravenously, in the experiments proper were made from dead degenerated tubercle bacilli used in a standardized emulsion and a salt solution extract of living tubercle bacilli in which the fat had been softened with ether.

After giving the clinical autopsical and microscopical findings the authors show that none of the above animals lived long enough to overcome the acute effects of injecting a large number of bacteria into the circulation. The animals which had tuberculosis before beginning the experiment, particularly those where the lesions were more retrogressive, stood the injections better and showed a more increased tissue resistance than those which were markedly tubercular and the remainder which had only slight lesions or none at all. The animals with active lesions are not able to accommodate much extra toxin or to stimulate to any great extent the power of antibody formation.

An active immunity is therefore very difficult to attain. The methods employed here seem only to increase the power of the tissues to passive resistance.

Combating tuberculosis in female animals, E. VAN HUFFELEN (*Handel. Vlaamsch Natuur en Geneesk. Cong.*, 14 (1910), pp. 250-257).—This article deals in a general way with the prevalence of tuberculosis in female animals, chiefly cows in the Netherlands, and gives an exposition of the methods in vogue in that country for combating the disease.

Acid agglutination of bacteria, M. BENIASCH (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 12 (1912), No. 3, pp. 268-315; *Jour. Amer. Med. Assoc.*, 57 (1911), No. 25, pp. 1998, 1999; *abs. in Chem. Abs.*, 6 (1912), No. 7, p. 887).—“This acid agglutination of bacteria is, if anything, more sharply specific than is agglutination by immune serums. Typhoid bacilli can be distinguished from the various strains of paratyphoid and colon bacilli with the greatest ease, and bacilli so closely related that it is difficult or impossible to distinguish them by serum agglutination are readily identified by the optimum hydrogen ion concentration of their agglutination by acids. With various strains of typhoid bacilli the agglutinability by acids and serums runs parallel, and so it seems probable that the antisera and the acids act on the same constituent of the bacteria.”

The acid agglutination of the bacteria of the paratyphoid group, POPPE (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 13 (1912), No. 2, pp. 185-191).—The Michaelis method can be employed for identifying the bacteria representing the paratyphoid group. A differentiation of some of the lower forms in this group was not possible.

The nature and treatment of bovine piroplasmiasis in Germany, H. MIESSNER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 3 (1911), No. 4, pp. 207-230).—This paper consists largely of discussions of the vaccination and chemotherapeutic treatment of Texas fever. A bibliography of 23 titles is appended.

Agglutination reactions during the process of hog cholera serum production, W. GILTNER (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 60 (1911), No. 6, pp. 552-559).—Previously noted from another source (*E. S. R.*, 26, p. 785).

Study of the *Bacillus erysipelatis suis* (*Rhusiopathia suum*), H. THUM (*Rev. in Vet. Jour.*, 68 (1912), No. 443, pp. 301-304).—A general account, which is stated to be founded on practical experience.

In regard to the cause of equine influenza, J. BASSÉT (*Rec. Méd. Vét.*, 88 (1911), No. 17, pp. 546-552, fig. 3).—A detailed statement in regard to this work, which has already been noted (*E. S. R.*, 26, p. 381).

Concerning *Ascaris megaloccephala*, W. GREIM (*Über Ascaris Megaloccephala. Inaug. Diss., Univ. Giessen, 1910; abs. in Berlin. Tierärztl. Wchnschr.*, 28 (1912), No. 8, p. 141; *Vet. Rec.*, 24 (1912), No. 1236, p. 582).—The following are the conclusions drawn from the study of this parasite:

“The presence of *A. megaloccephala* may induce symptoms of disease in the horse. The *Ascaris* irritates the intestinal mucous membrane by its movements. By the aid of its lip apparatus, it scratches the mucous membrane and produces small wounds. Such lesions, when numerous and situated in close proximity to one another, may lead to inflammation, ulceration, and necrotic destruction of small portions of the mucous membrane. By its individual strength the *Ascaris* can not perforate the intestine. The parasites live free in the lumen of the intestine; and, contrary to the views repeatedly expressed hitherto, they are not able to suck from or to hook on to the intestinal mucous membrane. The *Ascaris* contains toxin in its body, and disperses it into its surroundings. The effects of the toxin consist of local irritation, alteration of the nervous system, and toxic action upon the heart and blood. An affection of the kidneys in connection with the excretion of the toxin can not be demon-

strated. The pathogenic importance of the parasite renders it necessary to administer anthelmintics to the horses infected with it."

Investigations of the action of "606" on spirochetosis of fowls, A. HAUER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 62 (1912), No. 6, pp. 477-496*).—The author finds that Salvarsan destroys spirochetes in fowls, its curative action being noticed as early as the day of administration. A bibliography of 31 titles is appended.

## RURAL ENGINEERING.

The primer of hydraulics, F. A. SMITH (*Chicago, 1911, pp. VI+217, figs. 108*).—This publication covers the more important mathematical, physical, and mechanical principles underlying the subject of hydraulics, and gives general information, formulas, and hydraulic tables to solve problems relating to the flow of water in channels in municipal, drainage, irrigation, or other hydraulic works.

Tables for converting discharge in second-feet per square mile into run-off in depth in inches and discharge in second-feet into run-off in acre-feet (*U. S. Geol. Survey, 1910, pp. 21*).

A review of masonry dam design and construction illustrated with cross sections of 40 notable dams (*Engin. and Contract., 37 (1912), No. 21, pp. 583-594, figs. 47*).—Brief descriptions of the design and construction of these irrigation and power dams are given with statements of cost.

Fourth biennial report of the state engineer and of the Carey Land Act Board of the State of Montana, 1909-10, J. W. WADE (*Bienn. Rpt. State Engin. Mont., 4 (1909-10), pp. 18*).—This report makes a brief statement of work by the Montana state engineer's office in 1909-10, and discusses the physical and financial condition of irrigation projects under the Carey Act in Montana in 1910.

Tenth biennial report of the state engineer of Wyoming, 1909-10, C. T. JOHNSTON (*Bienn. Rpt. State Engin. Wyo., 10 (1909-10), pp. 211, pls. 9, fig. 1*).—This report deals with the irrigation administration in Wyoming in 1909-10, gives lists of permits to appropriate irrigation water, tables of stream gagings, reports of superintendents of water divisions, and reports of the progress of reclamation works in the State.

Review of irrigation in India in 1909-10, W. B. GORDON (*Sup. Gaz. India, 1911, June 10, pp. 1099-1121*).—Tabulated data are reported showing the financial and other results of irrigation works in operation in India in 1909-10. The total area irrigated was about 22,500,000 acres, and the value of the crops raised thereon is estimated at about 116 per cent of the capital outlay.

Volume of water required in irrigation, M. RINGELMANN (*Rev. Hort. [Paris], 84 (1912), No. 7, pp. 160-162*).—It is stated in this article that the soil characteristics, the nature and age of the vegetation, and existing meteorological conditions largely govern the amount and frequency of irrigation required. The results of observations along these lines are given from different sources.

The use of slope-stake tables in irrigation work, R. C. PIERCE (*Engin. News, 67 (1912), No. 21, pp. 986, 987*).—The author explains the use of tables giving the distances out to the cut and fill stakes and the corresponding cuts in cross-sectioning irrigation ditches. The process, he claims, eliminates the errors in the mental calculations of the rodman and tapeman, reduces talking and signaling to a minimum, and saves time.

[An irrigation pumping plant], C. R. SESSIONS (*Pacific Rural Press, 83 (1912), No. 20, p. 467, fig. 1*).—A simple and economical irrigation pumping

outfit is described, consisting essentially of a 15-in. centrifugal pump directly connected to a single cylinder 30-horsepower distillate engine. The plant cost, completely installed, \$1,800, has a capacity of 6,500 gal. per minute, and it is claimed can irrigate about 10 acres of land in a 12-hour run.

**Automatic hydraulic pumping engine** (*Northwest Hort.*, 25 (1912), No. 5, pp. 129, 130).—An improved type of hydraulic ram is described, which, it is claimed, can be operated in larger units and under a larger range of conditions than the old type, and develops under ordinary working conditions from 75 to 95 per cent of efficiency. The following improvements are suggested for insuring high efficiency: A large waterway area through the valves, approximately equal to the area of the supply pipe, a small valve movement (maximum 1 in.), valves smoothly curved for easy passage of the water, close relative position of waste and discharge valves, eliminating the column of dead water to be started and stopped at each stroke, and the downward discharge using all available head.

**Practical methods of draining irrigated lands**, R. A. HART (*Nat. Land and Irrig. Jour.*, 5 (1912), No. 4, pp. 8-11, figs. 7).—Attention is called to the frequent importance of draining irrigated lands, and the methods of construction of open canal and covered tile drains applicable to the existing conditions in irrigated sections are briefly outlined. Special attention is paid to covered tile drains, of which 3 systems are discussed—the natural system, gridiron system, and intercepting system. A number of typical examples of tile drainage of irrigated lands are given, pointing out the special features. A cost of from \$10 to \$30 per acre, with an average of \$15 per acre, is claimed.

**Irregular channels retard the flow of water**, M. E. BRIGGS (*Nat. Land and Irrig. Jour.*, 5 (1912), No. 5, p. 31, figs. 2).—It is pointed out that a correct drainage ditch is obtained only when dug in a manner which will not disturb the earth in the banks or bottom, and with sufficient berm and side slopes to prevent slipping and caving of banks and waste banks when under water action.

**Tile drainage**, J. A. JEFFERY (*Michigan Sta. Spec. Bul.* 56, pp. 45, figs. 31).—This bulletin explains the working principles of tile drainage, discusses the general planning and location, with special reference to silt basins, and points out the benefits of tile drainage. The use of the drainage level and of simple leveling devices for establishing grades is explained and the entire procedure of making and mapping the survey and of making the necessary computations for a tile drainage system is outlined, with examples of notes and profiles. The process of constructing a tile drain is outlined in detail.

**New York state highways** (*Municipal Jour.*, 32 (1912), No. 20, pp. 739-747, figs. 16).—This article deals with the organization of the New York State Highway Commission, road maintenance, types of road construction, and road details and specifications, and discusses recent typical road construction work.

**Portland cement concrete roads**, L. W. PAGE (*Engin. Rec.*, 65 (1912), No. 21, pp. 578, 579).—This is a paper read before the American Association of Portland Cement Manufacturers, May 9, in which general suggestions are given relative to the construction of concrete roads and pavements. The advantages of concrete for roads and pavements pointed out are its ability to resist shear, to transmit normal pressure over a large area of subgrade, and to act as an arch to sustain normal pressure.

**The storage of Portland cement** (*Irrig. Age*, 27 (1912), No. 6, pp. 215, 216, figs. 2).—Attention is called to the importance of carefully storing Portland cement for protection against moisture, and methods of construction of temporary and permanent storage buildings are briefly outlined.

**Agricultural machines**, K. WALTHER (*Die landwirtschaftlichen Maschinen*, Leipzig, 1910, vol. 2, pp. 120, figs. 64; 1911, vol. 3, pp. 156, pl. 1, figs. 91).—These are the second and third volumes of this series, the first having been previously noted (E. S. R., 21, p. 186).

They treat of harvesting machinery and machinery for the cleaning, storing, preparing for use, etc., of the different crops after harvesting, describing the construction and methods of operation of mowing machines, binders, hay rakes, tedders and loaders, potato and turnip diggers, threshing machines, grain cleaning and sorting machines, hay presses, and feed preparing machines. There is also included a chapter on agricultural motors.

**Agricultural machinery**, G. COUTAN (*Bul. Soc. Agr. France*, 1912, Apr. 15, pp. 404-413; May 1, pp. 457-461, figs. 7).—Several agricultural machines are briefly described, among which are ground and crop cultivators, tractors, drills, and harvesters. The mechanical theories for some types of potato diggers and drills are illustrated and explained.

**The efficiency of the farm tractor**, R. BERESFORD (*Iowa Agr.*, 12 (1912), No. 7, pp. 12-14, figs. 2).—The author computes the cost of plowing by gas tractor at 40 cts. per acre, and by horses at 60 cts. per acre. He calls attention to a number of cases where gas tractors have proved efficient and profitable on farms.

[A 24-hour test of a tractor] (*Impl. and Mach. Rev.*, 37 (1912), No. 444, pp. 1573, 1574).—A 24-hour test was made of a 50-brake horsepower, 4-cylinder, 3-speed motor in plowing and pressing, the implements employed being a 4-furrow plow and a 36-in. 5-wheel land presser.

The results show that 20 acres 89 sq. yds. of land were plowed and pressed in 24 hours. The amount of gasoline used was 69½ gal., or about 3½ gal. per acre, and the amount of lubricating oil used 1¾ pt. per acre. The opinion is presented that a light, powerful, speedy tractor, drawing a comparatively small plow, is more efficient than a slower, heavier machine, pulling a greater number of plows.

**An effective stumping machine** (*Queensland Agr. Jour.*, 28 (1912), No. 4, pp. 290-292, figs. 2).—A stump puller and its method of operation are described. It consists essentially of an iron and wood frame supporting a wooden drum or roller which revolves by lever action and operates a block and tackle and steel cable pulling system. An illustration is given showing the working parts in detail.

[Trials of corn and seed drills] (*Impl. and Mach. Rev.*, 38 (1912), No. 445, pp. 70-74, figs. 9).—The method and results of tests on several makes of corn and seed drills for accuracy, even distribution of seed, simplicity, and general efficiency are given with the constructive details and the price of each machine.

**Milking with machines** (*Wiener Landw. Ztg.*, 62 (1912), No. 27, pp. 339, 340).—A discussion is given of the relative merits of suction and pressure milking machines, the advantages of light weight, simplicity, ease of adjustment, and speed in milking being conceded to the suction machines, and the advantages of steady and systematic action, easy control, ready cleaning and airing, complete milking, and easiness on the cow to the pressure machines. Several different makes of these two machines are described.

**Farm power**, L. W. CHASE (*Deseret Farmer*, 7 (1912), No. 28, p. 651, fig. 1).—Results of tests conducted at the University of Nebraska on gasoline engines, showing the gasoline consumed in different kinds of farm work, are reported.

From these tests and other computations it is estimated that 1 gal. of gasoline in a 3-horsepower engine will complete any one of the following operations:

Pump 2.454 gal. of water from a 43-ft. well, shell 264 bu. of corn, grind 48.6 bu. of corn, separate the milk from 300 cows, do 20 weekly washings, grind 20 sickles, or operate the machinery in harvesting 4 acres of grain.

Power that is needed (*Farm Machinery, 1912, No. 1074, p. 15*).—Data are given from actual tests of gasoline engines showing the power required for driving the different machinery about the farm.

[Generation of electricity by wind power in Denmark], V. MACERSTEIN (*Monatsh. Landw., 4 (1911), No. 2, pp. 35-40, figs. 3*).—Attention is called to the use of wind power for generating electrical energy for farm use, and a brief description and discussion of private and central plants are given with a short statement of cost.

What electricity means to the farmer, P. A. BATES (*Nat. Land. and Irrig. Jour., 5 (1912), No. 5, pp. 79, figs. 5*).—This article deals with the use of electricity on the farm, pointing out the advantages of immediate availability, adaptability, simplicity, economy, and reliability, and comparing farm work as done by electricity and as done by the old hand methods.

Electric light for the farm, N. H. SCHNEIDER (*New York and London, 1911, pp. IX+85+VIII+86, figs. 65*).—This work consists of two parts.

Part 1 contains practical information on small, low-voltage electric light plants, operated by storage batteries, suitable for farms, isolated houses, and country homes in general, explaining in detail how to estimate the size and number of lights required, their best location, and the most convenient means of control, and how to estimate the required capacity of, install, and operate the plant necessary to furnish the electric current. Part 2 deals with the wiring of houses for electric lights, with special reference to low-voltage battery systems, giving information on planning and installing the general wiring, installing the lights, switches, etc., methods of wiring for special buildings and to suit unusual conditions, and the general estimating of wiring material required. A chapter is included describing some typical plants.

Lighting system for the farm (*Farmer, 31 (1912), No. 19, pp. 686, 688, figs. 2*).—A description is given of the various modern systems used for supplying artificial light to the farm home, viz, acetylene gas, gasoline gas, electricity, blaugas, and improved lamp systems.

The electric system is considered the most efficient, although it has the highest initial cost. The following approximate costs are given for average-sized installations of each system: Acetylene gas \$250, gasoline gas \$100 and up, electricity from \$350 to \$450, and blaugas from \$100 to \$200.

Lighting with alcohol and kerosene, R. M. WEST (*Minnesota Sta. Bul. 126, pp. 97-127, figs. 4*).—The work outlined in this bulletin is primarily intended to determine the relative lighting values of industrial alcohol and kerosene, and in connection with this many factors of secondary importance are considered, such as safety, health, eyesight, cleanliness, cost of maintenance, original cost of lamp, and ease of manipulation. Five portable lamps, including both the mantle and wick types, and 1 lamp intended especially for alcohol, were selected for comparison and when possible both alcohol and kerosene were burned in the same lamp with the same mantle. The method of light measurements employed was the comparison of the lights with the light of a standard English candle by means of an open-bar photometer.

Tabulated results of these tests are given and are graphically represented by 6 sets of curves showing the ratio of the candlepower of the light to the candlepower hours per gallon of fuel. A seventh set of curves estimates the number of candlepower hours obtainable for \$1 in the case of the common illuminants, and shows that with kerosene at 6½ cts. per gallon a 16 candlepower light may

be maintained giving 17,000 candlepower hours for \$1, while in order to give the same economy, alcohol would have to sell at from 3 to 5½ cts. per gallon, gas at about 56 cts. per 1,000 cu. ft., and electricity at 9 cts. per kilowatt hour.

The conclusions drawn are that with all lamps tested, the greatest amount of light per unit of fuel is obtained at the maximum candlepower which the light will give; kerosene is uneconomical and inefficient when burned in the old-style lamp; mantle lamps for either fuel are efficient but require greater care in manipulation; with each fuel burned in the lamp best suited to its use, kerosene has the higher efficiency; the lighting value of alcohol is approximately one-half that of kerosene when both are burned in the same lamp under the same mantle; and alcohol burned in the special alcohol lamp gives only a slightly lower efficiency than kerosene in mantle lamps.

As regards the further improvement of lighting apparatus, it is predicted that while the absolute amount of light obtainable with these fuels may be materially increased, it is doubtful if their relative lighting values will be greatly affected.

Plumbing for the farm home (*Farmer*, 31 (1912), No. 19, pp. 688, figs. 3).—Systems of plumbing and sewage disposal for the farm home are dealt with, a cheap and simple system of sewage disposal by septic tank and filter beds being described, which, it is stated, would cost about \$60.

## RURAL ECONOMICS.

Cooperation in the South, F. G. MINER (*Farmers' Rev.*, 44 (1912), No. 19, p. 4, figs. 2).—This article illustrates the principles of cooperation among farmers by showing what a cooperative organization of truck growers near Norfolk, Va., has done for its members in a financial way within the last few years. The organization has found it to be more advantageous to have all buyers come to its stations, where the products are sold f. o. b. than to ship direct to commercial firms. They have a shipping inspector and the inspection he gives is accepted as bona fide by the purchasers.

In addition to buying and selling for its members, the association loans money to them upon certain conditions.

Grange cooperation at work: How fire insurance companies and national banks are run by farmers, J. ALVIN (*Country Gent.*, 77 (1912), No. 20, pp. 4, 5, 29, fig. 1).—This article points out by a number of illustrations how fire insurance and banking both come within the scope of grange cooperation in Pennsylvania. Of the 200 or more mutual insurance companies in the State, 18 are carrying risks of over \$60,000,000 and are managed entirely by members of the grange.

Under the plan in operation when a members applies for insurance, an officer of the company examines his property and estimates its value. Should it be worth \$1,500, for example, insurance is granted to the amount of \$1,000, on giving a note for \$50 and paying a 5 per cent assessment thereon, or \$2.50. All other assessments are made annually as they may be needed to meet the losses. At the end of 5 years, the note, which is called a premium note and is the basis of the company's resources, is returned.

The principal advantage of such insurance is in the elimination of the overhead charge which is usually the largest item of insurance cost. For instance, one mutual fire insurance company carried risks in 1911 of over \$500,000 and the total expenses amounted to only \$51.99. Another company was carrying, on January 1, 1912, insurance to the amount of \$11,716,079, and the average expense per year for the last 37 years is shown to have been \$1,641.31 and

the average cost of insurance per \$1,000 for 1 year \$1.90. Still another company is carrying \$4,139,950 of insurance and its annual expenses, including salaries and all items, are less than \$2,600.

Data as to the work and success of a number of other insurance companies, together with that of the grange banks, are given.

The cost of production of farm crops, F. W. GIST (*Proc. Middle Tenn. Farmers' Inst.*, 10 (1911), pp. 81-90).—An address delivered at the tenth annual session of the middle Tennessee Farmers' Institute, Nashville, Tenn., December 5-7, 1911, in which the author discusses and points out in detail, as a result of his investigations, some conclusions as to what ought to be included in the cost of production as it relates to the business of farming.

A rural survey in Missouri (*New York* [1912], pp. 42, figs. 22).—This pamphlet presents the results of a social and economic survey made by the Department of Church and Country Life of the Board of Home Missions of the Presbyterian Church. It includes Adair, Sullivan, and Knox counties, Missouri, comprising a total area of 1,719 square miles with a population of 53,701. Detailed information is reported for each township as to its topography, economic conditions, population, and educational, social, and religious conditions and activities.

Of the total population, 35,495 live in the country, 5,551 in 23 villages under 750 in population, and the remaining 12,655 in towns of more than 750 population. The population in the rural districts shows a decrease, while that in townships has increased, but the total population of the three counties is 1,788 less in 1910 than in 1900. The reasons assigned for this condition are (1) smaller families, (2) the increased use of farm machinery, lessening the need of farm hands, (3) the increased value of land, which has induced some farmers (as a rule the owners of the small farm) to sell out and go to cheaper lands in the West, and (4) the fact that the younger generation has been seeking greater opportunities in towns and in the cheaper lands elsewhere.

About 85 per cent of the farmers own the farms they operate, the remainder being tenants. Agricultural laborers receive from \$20 to \$30 and "keep" per month. The average family is shown to spend annually \$771 on itself, \$13.72 on its school, \$6 on its roads, and \$3.18 on its church. It is stated that only 29 per cent of the total population belong to a church, and that 44 per cent of the tenants, 78 per cent of the hired men, 65 per cent of farmers who own 20 acres of land, 46 per cent of farmers with 40 acres, 36 per cent with 60 acres, 27 per cent with 100 acres, 20 per cent with 200 acres, and 18 per cent with 500 acres do not attend. The question is raised whether the poor man does not want to go to church or whether the church makes no effort to get him to do so.

[Agricultural production in Victoria], A. M. LAUGHTON (*Victorian Year-book*, 31 (1910-11), pp. 623-707).—Notes, statistics, and detailed accounts of agricultural production of the State for 1910-11, with comparisons with former years and with other States and countries, are here presented, together with a brief summary of the work in progress at the agricultural schools, colleges, and experiment stations.

It is noted that the number of persons engaged in agricultural pursuits in 1901 was 78,539 males and 17,381 females, and that the persons employed in farming, dairying, and pastoral holdings in 1910 numbered 99,948 males and 54,083 females, the total population being 651,093 males and 656,305 females. The prevalent rates of wages paid (with rations) during 1910-11 were: Plowmen 25s. per week, farm laborers 20s., milkers 20s., harvest hands 6s. per day, and threshing machine hands 8d. per hour. The area under the 5 principal

crops, their production, and the proportion of each to the population are shown in the following table:

*Area, production, and average per head of population of the 5 principal crops in Victoria, 1901 and 1911.*

Crops.	Area.		Production.		Average production per head of population.	
	1901	1911	1901	1911	1901	1911
	<i>Acres.</i>	<i>Acres.</i>	<i>Bu.</i>	<i>Bu.</i>	<i>Bu.</i>	<i>Bu.</i>
Wheat.....	2,017,321	2,398,089	17,847,321	34,813,019	14.91	26.63
Oats.....	362,689	392,681	9,582,322	9,690,127	8.00	7.42
Barley.....	58,853	52,687	1,215,478	1,340,387	1.02	1.03
			<i>Tons.</i>	<i>Tons.</i>	<i>Tons.</i>	<i>Tons.</i>
Potatoes.....	38,477	62,904	123,126	163,312	0.10	0.13
Hay.....	502,105	832,669	677,757	1,292,410	.57	.99

The number of dairy cows is shown to have increased from 515,179 in 1903 to 668,777 in 1910, the production of butter from 46,685,727 lbs. to 70,603,787 lbs. and the number of cream separators in use from 8,986 to 27,307. The Victorian wool clip for the year from sheep amounted to 73,959,226 lbs., from lambs to 6,115,044 lbs. During 1910 there were exported to foreign countries 164,213,073 lbs. of wool, of which 76,068,574 lbs. had been imported from other States.

**Agriculture [in New Zealand], M. FRASER** (*New Zeal. Off. Yearbook 1911*, pp. 551-565).—Notes and statistics showing the land in cultivation and acreage under various crops with their yields are here presented. The area under wheat in 1911 was 322,167 acres, oats 302,827 acres, with the average yield 25.73 bu. and 33.41 bu., respectively, per acre.

**Agriculture in New Zealand, M. MURPHY** (*New Zeal. Off. Yearbook 1911*, pp. 785-815).—A résumé of agricultural conditions in New Zealand for 1911, showing the acreage production of a number of crops, growth of the live stock and dairying industries, and the farming outlook of the Dominion in general (E. S. R., 25, p. 391).

[Papers on Danish agriculture] (*Tidsskr. Landökonomi, 1911, Nos. 7, pp. 457-470; 8, pp. 521-538; 9, pp. 569-586, 587-602; 12, pp. 681-704; 13, pp. 737-749*).—The usual summaries and reviews of the main branches of Danish agriculture are here presented. Particular attention may be directed to the following: Horse Raising, by J. Jensen (pp. 457-470); Animal Husbandry, by A. Appel (pp. 521-538, 587-602); Agricultural Crops, by K. Hansen (pp. 569-586); Agricultural Imports and Exports, by N. C. Christensen (pp. 681-704); and Butter Exports 1910-11, by B. Bøggild (pp. 737-749).

**Agriculture and forestry [in Austria] (Österr. Statist. Handb., 29 (1910), pp. 120-147)**.—Official statistics are presented regarding agriculture and forestry in Austria, showing in particular the basis of land taxation and the influence it has on the different types of farming, for example, the effect it has upon the acreage in field crops, meadows, pasture lands, gardens, vineyards, etc.

[Agricultural statistics in Japan] (*Statist. Rpt. Dept. Agr. and Com. Japan, 27 (1912), pp. 1-108*).—A statistical report, showing the area, production, yield, etc., of all kinds of farm crops in Japan, and how they are distributed, together with data as to poultry, eggs, live stock, and other farm activities of the country (E. S. R., 24, p. 493).

**Wholesale prices in Canada, S. F. CULVER** (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 115, pp. 618, 619).—This report brings out the fact that wholesale prices in Canada reached during 1911 a general level higher than in any previous year within the present generation. The prices of grains and fodder increased 5.8 per cent over 1910, fish 1.5 per cent, and other foods 11.8 per cent, although the prices of animals and meats decreased 10.2 per cent and dairy products 0.9 per cent. This decline is attributed to feed shortage. Imported foods, including sugar, were decidedly higher. Potatoes sold at \$1.24 a bushel, compared with 58.3 cents in 1910. Prices of flour and apples were lower while peaches and pears were higher than in 1910.

**Prices and wages in India** (*Prices and Wages India*, 28 (1911), pp. VI+230).—Tabular statements giving details as to average annual retail prices of the leading crops and the prices of staple articles of import and export in 1873 and from 1886 to 1911 in British India, together with statements as to average monthly wages of skilled and unskilled labor at the end of 1873 and of each year since 1886.

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statist. Crop Reporter*, 14 (1912), No. 5, pp. 33-40, figs. 2).—Tables and notes are given showing cotton acreage and yield per acre in 1911, by States; crop conditions May 1, 1912, with comparisons; the mean dates when the planting of specified crops begins, is most general, and ends, by States; farm value of important products on particular dates, by States; production, marketings, variation in prices of eggs, and averages paid to producers in the United States; causes and extent of cotton damage, 1909-1911; mileage operated by railroads making organized efforts to promote agriculture; monthly receipts and stocks of eggs and poultry in the United States; range of prices of agricultural products at important markets; condition in terms of prospective yield per acre of a number of crops, based upon averages for the five years, 1906-1910; and temperature and precipitation statistics.

It is noted that 30 per cent of the farmers of the corn area of the United States tested their seed corn with an average germination of 85.2 per cent.

### AGRICULTURAL EDUCATION.

**How the States may aid their farmers, A. C. TRUE** (*Country Gent.*, 77 (1912), No. 18, p. 6).—The varied functions performed by state departments of agriculture are briefly mentioned, and their functions under an ideal system of state government are discussed. According to this system state departments of agriculture would be considered as branches of state governments the fundamental business of which would be the execution of the laws relating to agriculture, involving, for example, the control of fertilizers, feeding stuffs, plant and animal diseases, injurious insects, management of state forests, fairs, etc. It should also be their business to provide a method for the regular collection and dissemination of economic data relating to agriculture and rural communities, by thoroughly trained statisticians and economists. They should be relieved of responsibility for farmers' institutes and other forms of educational extension, as well as for research work, which are lines of work more properly belonging to the agricultural colleges and experiment stations, and, in turn, these latter institutions should be freed from police duties and other administrative functions. "The great lines of cleavage for the experiment stations, agricultural colleges, and state departments of agriculture are indicated by the terms research, education, and administration," but in each State there should be worked out a system of coordination and cooperation among all public agencies for the advancement of agriculture.

[Agricultural instruction in general, and its adaptation, particularly of rural primary instruction, to the agricultural population of the country],

A. C. LE COCQ (*Rev. Agron. [Portugal]*, 9 (1911), No. 1-6, pp. 44-94).—In this article the author discusses the attributes, utility, and special features of agricultural education. He concludes (1) that in a general way the essential aim of this instruction should be to prepare and adapt the agricultural population of the country to the rural life and to the successful development of the agricultural industry; (2) that it should comprise rural elementary, professional, technical, and higher or scientific, special and itinerant instruction for adults, and normal agricultural instruction. The provisions of the law of December 21, 1901, with reference to agricultural instruction now in force are stated, from which it appears that the present organization corresponds almost completely with the plan outlined by the author with the exception that the itinerant instruction is provided for as a secondary function of the regional agronomes or the experiment stations, and no provision is made for the normal agricultural instruction.

Correlation of industrial and academic subjects in rural schools, ELLA G. AGNEW (*Hampton Leaflets*, 6 (1912), No. 6, pp. 8).—This leaflet has been compiled for the use of rural teachers, especially those in whose schools canning clubs are to be organized. The author describes the preparation of the cold frame and suggests how the growing of tomatoes may be correlated with the work in manual training, language, composition, spelling, drawing, arithmetic, soils in relation to agriculture, and physiology.

Forestry in agriculture, E. R. JACKSON (*Vocational Ed.*, 1 (1912), No. 3, pp. 184-192, figs. 5).—An outline is here given of a one month's course in elementary forestry, given last spring in the Baltimore County Agricultural High School as a part of the course in farm crops. The course included recitations, field trips to a nearby woodlot, and studies of forest and woodlot conditions in the vicinity.

Forestry in geography, E. R. JACKSON (*School Sci. and Math.*, 12 (1912), No. 4, pp. 271-277).—In this address, which was delivered at the 1911 session of the summer school of the University of Virginia, the meaning of geography, distribution and character of forests in the United States, national forests and national parks, the influence of forests upon topography, relations of forests to commerce, and the lesson of conservation, are considered.

The text-book of agricultural education and rural life: **Agricultural words** (*Columbus, Ohio: Assoc. Adv. Agr. Ed.* [1912], pp. 29).—This is a list of words commonly used in the teaching and practice of agriculture, and is intended to form the basis for the agricultural spelling contests conducted under the auspices of the Ohio Association for the Advancement of Agricultural Teaching.

A practical course in botany, ELIZA F. ANDREWS (*New York, Cincinnati, and Chicago* [1911], pp. IX+374, pls. 15, figs. 511).—In preparing this high school text-book of botany the author's aim was "to bring the study of botany into closer touch with the practical business of life by stressing its relations with agriculture, economics, and, in certain of its aspects, with sanitation."

The materials selected for experiment and illustration are those which are familiar and easily obtained, largely of the common cultivated kinds of plants. The study begins with the seed, follows with germination and growth, and then proceeds with roots, stems, and the other parts of the plant, the response of the plant to its surroundings, closing with a chapter on cryptogams and a very brief consideration of systematic botany.

The book contains numerous practical questions, many suggestions for field work, and outlines for 86 experiments.

Experiments with soils, J. W. HUNGATE (*Dept. Agr. State Normal School [Cheney, Wash.], Bul. A, No. 1, 1912, pp. 16, figs. 2*).—This bulletin has been prepared to assist the rural teacher in presenting in a very elementary way

the subject of soils and their care. Lists of laboratory equipment, references to useful soil literature, and 16 exercises on soils are given. Most of the exercises are followed by a brief discussion of the main principle involved.

**A seventh grade soil experiment.** C. F. PIMPS (*Nature-Study Rev.*, 8 (1912), No. 4, pp. 154-156).—A simple experiment in soil analysis is described which may be used in the seventh grade to correlate its science work with that of previous grades.

**Manual of laboratory exercises in farm crops.** M. L. FISHER (*Lafayette, Ind.: Purdue Univ.*, 1911, pp. 16).—These exercises are the results of several years of trial in the laboratory of exercises suited to the lectures accompanying 2 of the agronomy courses in Purdue University. The exercises include a study of vitality of seeds of different ages, determining the pure and germinable seed in a sample, an introductory study of clover and weed seeds, determining the percentage of hull in different varieties of oats, a study of mature wheat, rye, barley, emmer, and speltz heads, and the mature plant of oats, effect of temperature on germination, field study of clovers and grasses, inspection of field plats, identification of weeds and weed seeds, determination of moisture in grain, comparative grain judging, and commercial seed testing.

**Corn** (*W. Va. School Agr.*, 2 (1912), No. 7, pp. 133-161, figs. 13).—This bulletin discusses the history and types of corn, improvement of the crop, cultural methods, testing seed corn, selecting seed corn in the field, judging and scoring corn, some injurious insects, and corn products. A practicum is outlined and supplementary references for the further study of corn are given.

**The study of birds with a camera.** R. W. HEGNER (*Nature-Study Rev.*, 8 (1912), No. 4, pp. 132-137, figs. 3).—The methods employed in photographing birds' nests and adult wild birds to prove that no elaborate apparatus or exceptional skill are necessary to obtain first-class results.

**Alabama Bird Day book** (*Montgomery, Ala.: Dept. Game and Fish*, 1912, pp. 64, pls. 10).—This book contains a suggested program for Bird Day, bird poems, and brief studies of birds' eggs and of birds found in Alabama.

**Suggestions for crayfish study.** MARGARET W. TAGGART (*Nature-Study Rev.*, 8 (1912), No. 3, pp. 104-110, fig. 1).—This is a study of the crayfish, followed by a series of 15 problems on collecting the crayfish, its habits, etc.

**The insect life of pond and stream.** P. S. WELCH (*Nature-Study Rev.*, 8 (1912), No. 4, pp. 139-144, figs. 5).—This article gives instructions as to where and when to collect water insects, how to make observations of these insects in their native haunts, general methods of collecting, necessary collecting apparatus, and general methods of rearing, including directions for making and caring for aquariums for insects living in quiet water and those living in running water.

**The horse.** A. W. NOLAN (*W. Va. School Agr.*, 2 (1912), No. 5, pp. 91-109, figs. 7).—This bulletin comprises 6 lessons on breeds and types of horses, judging a horse, feeding and care of horses, good horsemanship, and diseases of the horse. Some of the lessons include practical exercises.

**Sheep and swine.** A. W. NOLAN (*W. Va. School Agr.*, 2 (1912), No. 6, pp. 113-129, figs. 9).—This bulletin contains 8 lessons, together with practical exercises, on the history and breeds of sheep, judging, care and feeding of sheep, care of lambs, and swine history, types and breeds and feeding and management.

**Annual report, 1911, Winnebago County schools.** O. J. KERN (*Ann. Rpt. Winnebago Co. [Ill.] Schools*, 1911, pp. 96, figs. 101).—The author compares the cost of the Seward and Harlem consolidated schools with that of the other schools of the county, and describes some features of their work. Other chapters are devoted to outdoor and indoor improvement and nature-study agriculture, including reports of school garden activities in the spring of 1911, the work of

the Rockford soil experiment field, boys' corn and judging contests, and organizations in Winnebago County for country life.

A school for colonial science, A. GRADENWITZ (*Sci. Amer. Sup.*, 73 (1912), No. 1893, pp. 232, 233, figs. 6).—The author gives an illustrated account of the equipment and work of the German Colonial Academy at Witzzenhausen, the main object of which is to train pupils for the various economic pursuits open to the individual colonist.

The meaning of extension work, W. E. GARRISON (*Col. Rec. [N. Mex. Col. Agr.]*, 5 (1911), No. 2, pp. 1-4).—Extension work is discussed and the following forms are briefly described: Farmers' institutes; boys' and girls' clubs; demonstration work; lectures, conferences, and exhibits in connection with the county fair, etc.; short courses at the college; demonstration trains; and correspondence courses.

An act providing for agricultural extension in Indiana, G. I. CHRISTIE (*Purdue Univ., Dept. Agr. Ext. A. E. Form 14, 1911, pp. 7*).—The full text of the 1911 law, together with a discussion of those sections relating to county farmers' institutes, is given.

The boys' and girls' industrial club of New Mexico (*Col. Rec. [N. Mex. Col. Agr.]*, 5 (1911), No. 2, pp. 4-10).—An account is given of the history of the club, its purpose, contests, and prizes.

Constitution and suggestions for organizing county boys' and girls' industrial clubs of New Mexico (*Col. Rec. [N. Mex. Col. Agr.]*, 5 (1911), No. 2, pp. 11-14).

Constitution and directions for organizing local boys' and girls' industrial clubs of New Mexico, W. T. CONWAY (*Col. Rec. [N. Mex. Col. Agr.]*, 5 (1911), No. 2, pp. 15-17).

[Oklahoma boys' and girls' junior agricultural clubs] (*Bul. Okla. Agr. and Mech. Col.*, 7 (1910), No. 11, pp. 10; 8 (1911), Nos. 17, pp. 7, figs. 7; 18, pp. 15, figs. 9; 19, pp. 7; 20, pp. 15, figs. 10; 21, pp. 3; 22, pp. 16, figs. 14; 24, pp. 13, fig. 1; 8 (1912), Nos. 27, pp. 4; 28, pp. 4; 29, pp. 4, fig. 1; 30, pp. 4; 31, pp. 4; 32, pp. 4; 33, pp. 4; 34, pp. 4, figs. 2).—This series of bulletins is being published for the members of the Oklahoma Junior Agricultural Clubs, especially for contest work, and give instruction concerning plans for the organization of boys' and girls' agricultural clubs, sewing, cooking, butter making, milk testing and dairy herd records, poultry raising, growing cotton, corn, Kafir corn, milo maize, broom corn, vegetables, flowers, and peanuts, home canning, and hog selection and feeding.

Idaho potato culture clubs, W. H. OLIN (*Col. Agr., Univ. Idaho Ext. Bul. 1, 1912, pp. 15, figs. 6*).—Directions are given for the organization, as well as rules and regulations, of Idaho potato culture clubs.

Corn-growing contest for boys (*Penn. State Col., Dept. Agr. Ext. Circ. [1911], pp. 4*).—An outline for corn-growing contests in boys' organizations in cooperation with the Pennsylvania State College is suggested.

Results of Georgia boys' corn club work in 1911, J. P. CAMPBELL (*Bul. Univ. Ga.*, 1912, No. 175, pp. 24, figs. 6).—The author gives an account of the history of the corn club movement in Georgia, the promotion and maintenance of boys' corn club work, district organizers of corn clubs, and results for 1911.

The organization of girls' clubs, MARY E. CRESWELL (*Bul. Univ. Ga.*, 1912, No. 174, pp. 8, figs. 2).—Directions are given for organizing girls' canning and poultry clubs in Georgia in 1912.

Stock judging contests for boys at county fairs, D. O. THOMPSON (*Purdue Univ., Dept. Agr. Ext. Bul. 4, 1912, pp. 12, figs. 6*).—This is a suggested announcement as to the contests to be held cooperatively by Purdue University and county fair associations in Indiana.

County fair stock judging contests for boys, J. H. SKINNER and G. I. CHRISTIE ([*Purdue Univ., Dept. Agr. Ext. Pamphlet*], pp. 4).—Rules, regulations, and other suggestions for conducting these contests are given.

County school fairs in Virginia, T. S. SETTLE (*Richmond, Va.: Dept. Pub. Instr., 1912, pp. 55, figs. 11*).—A typical county school fair is described and the history of the movement given. In 1911 there were 25 county fairs held, 10,000 school children competed for \$7,000 worth of prizes, and between 30,000 and 40,000 people attended. Detailed suggestions are made for conducting a county school fair, preparing premium lists for literary work, agriculture, home economics, manual training, and athletics, and preparing exhibits in the various classes, including score cards for judging the various articles exhibited.

Growing children in California gardens, C. A. STEEBINS (*Nature-Study Rev., 8 (1912), No. 2, pp. 67-74, figs. 2*).—An account is given of school garden work in the Ohio State Normal School, also of the plan of the University of California to make school life a copy of the community life.

Worcester garden city plan; or, the good citizens' factory, R. J. FLOODY (*Nature-Study Rev., 8 (1912), No. 4, pp. 145-150, figs. 3*).—This is a description of the garden city plan and an account of its development, object, and influence since it was started 5 years ago under the auspices of the Worcester Social Settlement in the "island district" of Worcester, Mass.

The garden city consists of a large group or city of little gardens, 10 by 20 ft., with streets, boulevards, squares, etc., like a miniature city. Dumps and vacant lots have been used. Each child is charged the sum of 5 cents for his garden, and given 5 packages of seeds and the ownership of all he raises. There are now 4 of these garden cities in which last season there were 1,000 young gardeners.

### MISCELLANEOUS.

Twenty-second Annual Report of Alabama College Station, 1909 (*Alabama Col. Sta. Rpt. 1909, pp. 31*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1909, and reports of the director and heads of departments on the work of the station during the year.

Twenty-third Annual Report of Alabama College Station, 1910 (*Alabama Col. Sta. Rpt. 1910, pp. 32*).—This contains data corresponding to the above for the fiscal year ended June 30, 1910.

Twenty-fourth Annual Report of Colorado Station, 1911 (*Colorado Sta. Rpt. 1911, pp. 75*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1911, a report of the director on the work and publications of the station, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Annual Report of Florida Station, 1911 (*Florida Sta. Rpt. 1911, pp. CVIII+XII, figs. 31*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1911, a list of the publications of the year, a general review of the work of the station during the year, departmental reports, and a list of the periodicals received by the station. Most of the experimental work reported is abstracted elsewhere in this issue.

Twenty-fourth Annual Report of Illinois Station, 1911 (*Illinois Sta. Rpt. 1911, pp. 16*).—This contains lists of the publications of the station since its establishment and during the fiscal year, a brief statement concerning the principal lines of work, and a financial statement for the fiscal year ended June 30, 1911.

Annual report of the director for the fiscal year ending June 30, 1911 (*Delaware Sta. Bul. 94, pp. 10*).—This contains the organization list and the report of the director on the work of the station. It includes a financial statement for the fiscal year ended June 30, 1911.

## NOTES.

---

**California Station.**—Work has been begun on a laboratory building at the Citrus substation at Riverside, for which a state appropriation is available. Dr. J. E. Coit has been appointed director of the laboratory.

**Connecticut College.**—Dr. A. F. Blakeslee has been granted a year's leave of absence for research work on the lower fungi at the Carnegie Station for Experimental Evolution.

**Hawaii College.**—During the winter and spring months the college conducted a short course for teachers, including 15 special lectures on Monday afternoons. The maximum attendance was 50, the average 25.

**Illinois University and Station.**—New professorships have been authorized in landscape art, animal pathology, and dairy husbandry, also an associate and an instructor in landscape art. B. S. Pickett, of the New Hampshire College and Station, has been appointed assistant professor of pomology, and J. J. Gardner, also of the New Hampshire College and Station, as instructor in pomology. Dr. John Detlefson, of the Bussey Institution, has been appointed assistant professor of a new division of genetics in the animal husbandry department, Dr. Walter E. Joseph instructor in animal husbandry, and V. A. Place assistant in animal husbandry. Dr. Otto Rahn, of the Michigan College and Station, has been appointed assistant professor of bacteriology.

**Kansas Station.**—According to a note in *Kansas Farmer*, A. M. Ten Eyck has resigned as superintendent of the Fort Hays substation.

**Kentucky University and Station.**—Dr. M. A. Scovell, director of the college of agriculture and director of the station since its establishment, died August 15 after an illness of two weeks. An account of his career will appear in a later issue.

**Massachusetts Station.**—B. G. Southwick, a 1912 graduate of the college, has been appointed secretary to the director, vice H. J. Baker, whose resignation has been previously noted.

**Minnesota University.**—Returns from a blank form sent to each alumnus of the school of agriculture who graduated previous to 1909 show that of the 385 men responding, 225 are farming at the present time and the remainder engaged in 34 occupations. Of the 119 women heard from, 69 are housekeepers, 34 teachers, and the balance engaged in 8 other occupations.

**Nebraska Station.**—John A. Ratcliff has been appointed assistant in experimental agronomy, and has entered upon his duties.

**Nevada University and Station.**—President J. E. Stubbs has been granted a year's leave of absence, during which time he will make a trip around the world. Dean Lewers will be acting president in his absence.

E. A. Howes, formerly with the seed branch of the Canadian Department of Agriculture, has been appointed professor of agronomy and agronomist. Dairy instruction is to be begun in the university, and V. E. Scott, formerly with the Dunn County Agricultural School of Menomonie, Wis., has been appointed instructor in dairying.

**New Hampshire College.**—President W. D. Gibbs has resigned to engage in business, retiring September 1.

**Cornell University.**—Plans are nearing completion for the forestry building, which is expected to be ready for occupancy in the fall of 1913. A three-story and attic brick structure, 142 by 54 feet, is contemplated. The ground floor will contain laboratories for wood technology and a timber-testing room, and the remaining floors will be devoted to offices, class rooms, laboratories for forest mensuration and utilization, silviculture, and dendrology, a museum, herbarium, drafting rooms, etc.

The New York State Grange has contributed \$600 for 12 scholarships in the college of agriculture, which were recently awarded after a competitive examination held in each county to which members of the grange 17 years of age or over were eligible.

**New York State Station.**—Among recent changes are the resignation of Miss Minerva Collins as assistant botanist, and the following appointments: Walter O. Gloyer as associate botanist, Richard F. Keeler, Reginald C. Collison, and W. J. O'Brien as assistant chemists, Bentley B. Fulton as assistant entomologist, James R. Brew as assistant bacteriologist, and Mancel T. Munn as assistant botanist.

**North Carolina College Station.**—The extension department operated an agricultural train over the Atlantic Coast Line Railroad July 23 to August 8, in which live stock, drainage, and farm implements were the main features. A car of horses, cattle, and hogs, and a car of implements were taken from the college farm, and demonstrations in plowing and the laying of tile were given at each of the two stops made daily. The attendance during the trip was more than 10,000.

Dr. Burton J. Ray, assistant chemist, has accepted the professorship of chemistry in the Porto Rico College, where special attention is to be given to the development of courses in sugar chemistry.

**Ohio State University.**—Dr. H. A. Weber, professor of agricultural chemistry since 1884, died June 14, at the age of 67 years. Prof. Weber received his undergraduate education at Otterbein University and in Germany, and was given the degree of Ph. D. from Ohio State University in 1879. Among other offices which he held during his long career were those of assistant chemist in the Ohio Geological Survey from 1869 to 1874, professor of chemistry in the University of Illinois from 1874 to 1882, chemist to the Illinois state boards of agriculture and health during the same period, and chemist to the State Dairy and Food Commission of Ohio from 1884 to 1897. He was also a member for several years of the committee on food standards of the Association of Official Agricultural Chemists.

Together with the late Director M. A. Scovell, Dr. Weber worked on the production of sugar from sorghum in 1883, and also studied at an early date, among other questions, the needs of soils for fertilizers, light as a factor in sugar production, and the development of root tubercles in water cultures. He was the author of *Select Courses in Qualitative Analysis*, the first edition of which appeared in 1871, and had also contributed to various chemical publications.

**Pennsylvania College and Station.**—W. J. Wright has resigned as instructor in horticulture and horticulturist to accept the directorship of the New York State School of Agriculture at Alfred.

**South Dakota College and Station.**—The appointment is noted of H. E. Erdmann as assistant in dairying.

**Tennessee University and Station.**—According to a recent issue of the *Southern Agriculturist*, the Southern Railway, in conjunction with the Virginia & Southwestern Railway, the Cincinnati, New Orleans & Texas Pacific Railway, and the Mobile & Ohio Railroad, has established three agricultural scholarships

in the university of \$300 a year for four years. The recipients must be from farms in a county traversed by the Southern Railway system, must be in need of financial assistance, and must agree to practice or teach agriculture for two years after graduation in territory contiguous to some line of the system.

At the suggestion of the station authorities the railroads have this summer been operating excursions from the various counties of east Tennessee to the station to give farmers an opportunity to become familiar with its work. These excursions have proved very successful.

Oscar Campbell has been appointed plat assistant at the West Tennessee substation, and G. L. Herrington has been appointed horticultural assistant.

**Utah College.**—L. A. Merrill, director of the extension division, has resigned to engage in commercial practice as an agricultural expert. The offices of the extension division were transferred from Salt Lake City to Logan September 1.

**Virginia Truck Station.**—P. T. Cole, assistant horticulturist, has resigned to become assistant agricultural commissioner to the St. Louis Southwestern Railway Company, with headquarters in St. Louis.

**Agriculture at Syracuse University.**—Announcement is made by the division of agriculture, established about a year ago in response to the demand "under which every progressive university is put to offer the opportunity for instruction in agriculture as part of a liberal and technical education," of courses in general agriculture, animal husbandry, dairying, horticulture, agricultural engineering, and a special course for teachers. F. W. Howe, formerly of this Office, is director of the division.

**General Agricultural Committees of Bankers' Associations.**—Over 200 delegates, representing the agricultural committees of the bankers' associations of 22 States, met at Minneapolis and St. Paul August 7 and 8 for a discussion of agricultural education and improvement. Among the speakers were Thomas P. Cooper, secretary of the North Dakota Farming Association, President A. M. Soule, of the Georgia College; J. J. Hill; A. V. Storm, of the University of Minnesota; and S. M. Jordan, manager of the Pettis County Bureau of Agriculture, of Sedalia, Mo., all of whom discussed various phases of extension work.

A silver trophy offered to the State committee making the largest contribution to agricultural education and improvement was awarded to that of North Dakota, where the committee reported financing the better farming association to the extent of \$45,000, also contributing \$5,000 for farmers' institutes in the absence of a State appropriation, and \$5,000 for holding local corn-growing contests, in which over 11,000 men and boys participated. Joseph Chapman, jr., and Charles R. Forst, both of Minneapolis, were reelected president and secretary, respectively, for the ensuing year.

**Illinois Country Life Conference.**—A state conference on country life was held at De Kalb, Ill., August 1 and 2, which called together representatives of every type of rural organization and discussed all phases of country life. A most unique and helpful feature of this conference was a country life exhibit, to which many local and national organizations contributed. The conference was the second annual meeting of the Illinois Federation for Country Life Progress, a State-wide organization designed to unite all rural progress agencies of Illinois in one large, comprehensive campaign for the improvement of country life.

**Second International Congress of Entomology.**—This congress was held at Oxford August 5 to 9 under the presidency of Prof. E. B. Poulton and with representatives of about 20 countries in attendance.

In the section of economic entomology a paper was presented by Sir Daniel Morris, on behalf of H. A. Ballou, on Some Entomological Problems of the West Indies, with particular reference to insect control through the introduction of parasites. A. G. L. Rogers discussed the question of quarantine regulations, and his proposal of an international commission in connection with the International Institute of Agriculture met with the approval of the congress.

The next congress is to be held in Vienna in 1915, under the presidency of Prof. Anton Handlirsch.

**International Association of Poultry Instructors and Investigators.**—The first conference of this association took place in London July 18 to 24, with 27 countries represented. Lord Lucas, parliamentary secretary of the board of agriculture and fisheries, welcomed the delegates on the part of the British Government, and stated that the establishment of a national poultry institute for the scientific study of questions related to poultry husbandry and where instructors for the county work may be trained was receiving consideration.

A permanent organization was effected, E. Brown, of London, England, being chosen president, and Dr. Raymond Pearl, of the Maine Station, secretary.

A resolution was adopted providing for holding in 1914 a world's poultry congress, representing all sections of the industry. The association voted to institute fellowships to be conferred on such persons as shall have rendered service of the highest distinction to the advancement of the poultry industry. These fellowships are to be conferred by vote of the entire association, and are restricted in number to five every three years.

A central bureau of information is to be established, located for the present in London, and to contain an historical section, illustrative material, etc. The publication of a journal is also contemplated.

**American Association of Instructors and Investigators in Poultry Husbandry.**—At the fifth annual meeting of the International Association of Instructors and Investigators in Poultry Husbandry, in connection with the recent session of the Graduate School, a change of name to American Association of Instructors and Investigators in Poultry Husbandry was adopted. Horace Atwood, of the West Virginia University and Station, was elected president; J. C. Graham, of the Massachusetts College, and H. L. Kempster, of the University of Missouri, vice presidents; and Homer W. Jackson, of Buffalo, N. Y., secretary-treasurer.

**Miscellaneous.**—Charles H. T. Townsend has been appointed in charge of the Estacion de Entomologia, which will comprise all government entomological work in Peru, and will have its headquarters at Lima. E. W. Rust, who has been associated with Mr. Townsend, is to remain at Puzra in charge of a sub-station to combat cotton plagues.

M. A. Carleton, for the past 18 years in charge of the grain investigations of this department, has been given charge of the work of the Pennsylvania Chestnut Tree Blight Commission.

S. A. Bedford has succeeded J. J. Golden as deputy minister of agriculture for Manitoba.

Walter Morrison has made a third gift of \$50,000 to Oxford University for the promotion of agricultural work.

King George V has conferred the honor of knighthood on Harry James Veitch for distinguished work in horticulture.

 STATION

## CONTENTS OF VOL. XXVII, NO. 5.

Editorial notes:	Page.
Dr. M. A. Scovell, deceased.....	401
Recent work in agricultural science.....	406
Notes.....	493

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Physical chemistry and agriculture, Ulpiani.....	406
Agricultural chemistry, Klinkerfues.....	406
Phytin and phosphoric acid esters of inosit, Anderson.....	406
Method of preparing tyrosin and glutaminic acid, Abderhalden.....	406
Identity of the guanin pentosid prepared from molasses, Schulze and Trier....	407
Extraction of alcohol and water-soluble phosphorus compounds, Ulrich.....	407
The mode of action of phosphatase, I, Euler and Kullberg.....	407
In regard to the action of phosphatase, Euler and Kullberg.....	407
Regulatory formation of the enzym tannase, Knudson.....	408
Separation of peroxidase from catalase, Kasanski.....	408
Action of emulsin upon salicin in an alcoholic medium, Bourquelot and Bridel.	408
The calcium carbid method for determining moisture, McNeil.....	408
The Kjeldahl method, Siegfried and Weidenhaupt.....	409
A practical method for reducing potassium platinic chlorid, Fiechter.....	409
The determination of potassium platinic chlorid, Trnka.....	409
Method for determination of small amounts of iron, Jahn.....	409
A modification of Marsh's apparatus for the detection of arsenic, Cohen.....	409

	Page.
Chemical composition of clay obtained in Schloesing-Grandeau method, Blanck.	409
A precipitin with which to differentiate boiled insoluble protein, Schmidt.....	410
Utility of ester method for monoamino acids, Abderhalden and Hanslian.....	410
Comparative study of methods for phosphorus in vegetable products, Ponte....	410
The ash of vinegar, Remington.....	410
The Fiehe reaction for the examination of honey, Stöcklin.....	410
The occurrence of boric acid in honey, Büttner.....	410
Detection of nitric acid in watered fruit juices, Cohn.....	411
Methods for sugar analysis and allied determinations, Given.....	411
Lactose and the by-products of lactose manufacture, Burr and Berberich.....	411
The chemical and bacteriological methods for examining milk, Rühm.....	411
What is the best test for judging the quality of milk? Stapenséa.....	411
Methods for determining iron in milk, Nottbohm and Weisswange.....	411
The iron content of cow's milk, Edelstein and von Csonka.....	412
Notes on the analysis of margarin, Cribb and Richards.....	412
Time required to sterilize canned goods at different temperatures, Serger.....	412
The preparation of berry and other fruit wines, Arauner.....	412
Milling of cane considered in relation to volume occupied by the fiber, Deerr..	412
Stohmann's handbook of sugar manufacture, revised by Schander.....	413
Centenary of the manufacture of beet sugar, 1812-1912, Lindet.....	413
Thirty-fourth report of Swiss Agricultural-Chemical Institute at Zurich, 1911..	413

## METEOROLOGY—WATER.

Weather and agriculture, Schmauss.....	413
Monthly Weather Review.....	413
General weather review, 1910-11, Esten and Mason.....	414
Meteorological observations.....	414
Report of the meteorologist, Stockton.....	414
[Meteorology of Finland].....	414
"Red rain" dust, Steel.....	414
Predicting water supply for the farmer, Alter.....	415

## SOILS—FERTILIZERS.

Investigations on soils from crystalline rocks in process of weathering, Busch...	415
Gray sand and hardpan (Ortstein), Wilhelm Graf zu Leiningen.....	416
Regarding brown soils, Glinka.....	416
Unproductive black soils, Conner and Abbott.....	416
The soils of Alabama and their adaptations to crops, Duggar.....	417
[Analyses of soils of the Burihat Station Farm].....	417
Weeds in relation to soils, Brenchley.....	417
The chemical characterization of soils, Russell.....	417
More recent investigations in soils science, Albert.....	417
Colloid chemistry studies on humus in limed and unlimed soils, Thaer.....	417
Concentration of phosphoric acid near the old centers, Hughes and Aladjem....	418
Radium and thorium emanations in the air of certain soils, Satterly.....	418
Production and movement of nitric nitrogen in soils, Stewart and Greaves....	418
Nitrates in soils, Stevens.....	419
The influence of molasses on nitrification in cane soils, Peck.....	419
Bacteriological studies of fixation of nitrogen in Colorado soils, Sackett.....	419
Regarding legume cultivation and inoculation experiments, Eichinger.....	419
New method of soil aeration.....	419
On the penetration of soluble fertilizers into the soil, Demolon and Brouet....	420
Chemical composition of manure as a measure of value, Crowther and Ruston..	420
The manufacture of nitrates from the atmosphere, Scott.....	420
The manufacture of nitrates from the atmosphere, Cottrell.....	420
Potash salts a protection against frost, Maas.....	421
Potash salts a protection against frost, Golte.....	421
Fertilizer experiments with ground phonolite, Thaer.....	421
Results of investigations of the potash deposits of Upper Alsace, Förster.....	421
The composition of the Pacific kelps, Turrentine.....	421
Significance of the word kainit, Zaragüeta.....	422
Discovery of chalk and phosphatic sands in the Yonne, France, Negre.....	422
Report on departmental experiments with ground limestone, Colbourn.....	422
Some bacteriological effects of liming, Brown.....	422
Experiments on the action of sulphur as a fertilizer in 1911, Bernhard.....	422

	Page.
The fertilizing action of sulphur, Degruilly.....	422
Sulphur as a fertilizer.....	422
Sand and ashes from Vesuvius, Casoria.....	422
Artificial manures in Hungary, De Miklós de Miklosvár.....	422
The consumption of chemical and mineral fertilizers in Spain, Gallego.....	423
Analyses of commercial fertilizers in Mississippi, 1911-12, Hand et al.....	423
Analyses of fertilizers, spring season, 1912, Kilgore et al.....	423
The inspection of cotton-seed meal, season 1911-12, Hand et al.....	423
The mixing of fertilizers, Vecchi.....	423
Home mixing and general fertilizer formulas.....	423

## AGRICULTURAL BOTANY.

Practical botany, Bergen and Caldwell.....	423
A laboratory manual of general agricultural bacteriology, Hastings et al.....	423
A biologic and taxonomic study of the genus <i>Gymnosporangium</i> , Kern.....	424
Natural history, etc., of <i>Azotobacter chroococcum</i> , Prazmowski.....	424
The physiology of denitrifying bacteria, von Caron.....	424
Metabolism and translocation in young foliage trees, Bauer.....	425
The periodicity of nutritive processes in young beeches, Kübler.....	425
The periodicity of synthetic processes in young foliage trees, Bauer.....	425
Influence of atmospheric oxygen on proteolytic ferments, Palladin and Kraule.....	426
Significance of respiration pigments in oxidation processes of plants, Palladin.....	426
Influence of diastase and emulsin on the respiration of plants, L'vov.....	426
Relation of protoplasmic-streaming movements to starch grains, Heilbronn.....	426
The carbohydrates of the snowdrop leaf, Parkin.....	427
Origin and function of pentosans in plants, Ravenna, Cereser, and Montanari.....	427
Significance of mucilage in the germination of seeds, Ravenna and Zamorani.....	427
Dimorphism of chlorophyll grains in some plants, Giovannozzi.....	427
Remarks on a new method of studying stomatal aperture of stomata, Stein.....	427
Heterozygosis in evolution and in plant breeding, East and Hayes.....	428
Inheritance of red color, and self-fertilization in jute, Finlow and Burkill.....	428
Department of botanical research, MacDougal.....	428

## FIELD CROPS.

Water requirements of crops in India. II, Leather.....	429
[Dry farming soil preparation methods], Richardson.....	429
[Field crops at the Delta substation, 1911], Walker.....	429
[Cabbage and potatoes at the New Mexico Station], Garcia.....	430
Results of cooperative experimental work for 1911, Tarbox, jr.....	430
Tables of field crops, Harper.....	430
Competition in cereals, Montgomery.....	430
The manuring of grass land.....	431
The grasses and grass-like plants of New Mexico, Wootton and Standley.....	431
Studies in Indian fiber plants, Howard.....	431
Peruvian alfalfa, Opazo.....	431
Lucern.....	431
Tests of treated and untreated beet seed, Günther.....	431
Germination tests of the different colored seeds of red clover, Kajanus.....	431
Native seed corn, Montgomery.....	432
Studies in water requirements of corn, Montgomery and Kiesselbach.....	432
The "Williamson Plan" of corn culture.....	433
Cotton in Hawaii, McClelland and Sahr.....	433
Recent cotton experiments.....	433
Note on the present position of cotton investigation in India, Coventry.....	434
[Flax experiments in India], Vandekerkhove.....	435
Ragged Jack kale.....	435
Black oats, McDonald et al.....	435
Fertilizers and the growth of rice, Zamora.....	435
Correlation in rye, Lehn.....	435
Soy beans, Ingalls.....	435
The growth of sugar beet.....	435
Experiments on cultivation of sugar cane at Partabgarh, 1909-1911, Clarke et al.....	435
Sweet potato investigation, Keitt.....	435
Crop rotation and fertilizer experiments with sun-cured tobacco, Green.....	436
Growing and curing sun-cured tobacco, Green.....	436

	Page.
Crop rotation and fertilizer experiments with bright tobacco, Cocke.....	437
Wheat breeding experiments, Montgomery.....	437
Is Federation wheat degenerating? Pridham.....	437
Twenty-five years' plant improvement in Sweden, Nilsson.....	437

## HORTICULTURE.

Radium as a means of forcing plants, Molisch.....	437
New garden plants of the year 1911.....	438
Report of division of horticulture of the Central Station, 1911, Calvino.....	438
Home gardening in South Carolina, Newman.....	438
Growing <i>Denia</i> onion seed, Garcia.....	438
Impediments to the vegetable industry and their control, Kindshoven.....	438
Pomology.....	438
Fruit culture, Goethe.....	439
How to grow and market fruit.....	439
The California fruits and how to grow them, Wickson.....	439
Experiments on the pollination of our hardy fruits, Hooper.....	439
Orchard heating, Greene.....	439
How a Ventura lemon grove was protected, Teague.....	439
New heater and vaporizer for frost protection, McAdie.....	439
Temperature injurious to peaches, apples, and pears.....	439
Tests of summer sprays on apples, peaches, etc., Clinton and Britton.....	439
Orchard spraying experiments, Bonns.....	440
Analyses of materials sold as insecticides and fungicides.....	441
The precooling of fruit in the United States, Dennis.....	441
Refrigeration in relation to fruit growing in Canada, Ruddick.....	441
Breeding citrus trees, Shamel.....	441
Work for citrus improvement, Coit.....	441
Viticulture.....	441
[Report of the viticultural branch], Blunno.....	441
A new process of grafting American grapes, Bunert.....	442
Making a rock garden, Adams.....	442
Making a garden to bloom this year, Tabor.....	442

## FORESTRY.

Key to trees of northeastern United States and Canada, Collins and Preston... ..	442
Key to the wild and cultivated trees in autumn, Darling.....	442
The seedlings of the live oak and white oak, Coker.....	442
Tulipwoods and tulip trees, Dallimore.....	442
Eucalyptus, its history, growth, and utilization, Sellers.....	442
Camphor from <i>Cinnamomum camphora</i> in the Federated Malay States, Eaton..	442
[Rubber tapping experiments], Newport.....	442
The woodlot for central Indiana, Pegg and Thomas.....	442
Wood-using industries and National Forests of Arkansas.....	443
Forest products of Canada, 1911.—Pulpwood, MacMillan et al.....	443
Strength tests of cross-arms, Wilson.....	443
The preservation of mine timbers, Peters.....	443
Silviculture.....	444
Influence of light and extreme temperatures on forest seed, Pittauer.....	444
The selection strip-felling and its system, Wagner.....	444
The lightning danger of various trees, Stahl.....	444
Forest fire protection under the Weeks law in cooperation with States, Peters..	444
Eighth annual report of the state forester of Massachusetts, Rane.....	444
Progress report of forest administration in the Andamans, 1910-11, Farrington..	445

## DISEASES OF PLANTS.

Four new fungus diseases in Iowa, Pammel and King.....	445
Notes on fungus diseases, Moore.....	445
Fungi exotici: XIII, Masseur.....	445
The seed treatment of summer grains, Hiltner.....	445
Control of grain smuts, Westerdijk.....	445
Cotton anthracnose, Barre.....	446

# EXPERIMENT STATION RECORD.

---

VOL. XXVII.

OCTOBER, 1912.

No. 5.

Record has already been made in these pages of the untimely death of Dr. M. A. Scovell, director of the Kentucky Experiment Station and head of the agricultural department of the State University. But the position of this man and the high esteem and affection in which he was held demand for him more than formal notice.

Melville Amasa Scovell was born at Broadway, N. J., February 26, 1855. At the time of his death, therefore, on August 15 last, he was in his fifty-eighth year. His apparent recovery from his sickness of a few years ago, and the general robustness and vigor which characterized him, gave him the appearance of being in the prime of life and seemed to promise many years of service. His taking away at a time when the results of so many years of labor were coming into fruition and the outlook for the future was so bright seemed especially to be regretted. But he lived to see his ambitions realized in an attitude of public appreciation for agricultural education and research in his State, permanent financial support for them, and an equipment for the experiment station equalled in few States. These were in an unusual measure the product of his own labors, and will remain a monument to his memory.

Dr. Scovell's collegiate work was done at the University of Illinois, then the State Industrial University, where he graduated in 1875 with the degree of B. S., specializing in chemistry. He remained with the university for seven years after graduation, being successively instructor in chemistry, assistant professor, and later professor of agricultural chemistry. He received the degree of M. S. from the university in 1877, and of Ph. D. in 1908. While at the university he gave considerable study to the production of sugar from sorghum, working out with the late Prof. H. A. Weber a method for obtaining sugar from this plant in quantities which at prevailing prices was thought profitable. In 1883 and 1884 he was superintendent of the Kansas Sugar Works at Sterling, Kans., and the following year was special agent for this Department in the erection of diffusion batteries for extracting sugar from sorghum and sugar cane in Kansas and Louisiana.

The Kentucky Agricultural Experiment Station was established in the summer of 1885 and Professor Scovell was elected as director, assuming his duties in November of that year. His continuous period of service as director for twenty-seven years is exceeded by only one case, that of Dr. E. W. Hilgard of California. It places the Kentucky Station in the unique position of having suffered no change in its administrative head since its establishment, a fact which is the more remarkable when the frequent change at most of these institutions in the early days is considered.

The beginning of the station was a meager one, and its resources were very limited. There were no special funds for its maintenance, and little in the way of facilities and equipment. One large room in the basement of the college building was assigned to the station, and this by subdivision was made to serve as office, chemical laboratory, and balance room. About twelve acres of land, all the tillable land the college then had, was assigned to the station for field experiments. The director was the only person whose time was devoted exclusively to the station work, and upon him devolved in large measure both the planning and the execution of the work.

In 1886 the legislature so modified the existing law relating to the sale of commercial fertilizers as to place the station in charge of the fertilizer control and give it the benefit of the fees. This was the first formal recognition of the station as a state institution. The following year a farm of about forty-eight acres was added, and a station building was provided in 1888. A second farm of sixty-four acres was acquired in 1898, to provide increased facilities for the field and feeding experiments, and subsequently other additions were made until the station fields assumed their present generous proportions.

To the fertilizer control was later added the state food control and the feeding stuff, nursery stock, and seed inspection, which provided a steadily increasing revenue. While these inspection duties made large demands upon the station, the work was so organized as not to interfere seriously with the experimental work, and new departments were added as the funds permitted. In 1905, the station having outgrown its quarters a new building, thoroughly modern and complete in all its appointments, was erected. This in time also became inadequate, and the past year an addition, larger than the original structure and costing about \$50,000, was begun.

During these years much of the time and effort of Professor Scovell were occupied in securing and preparing for use the buildings and land which he felt were required for the proper equipment of the station. These were provided in very large measure out of the earnings of the station, without specific state appropriation. This called for a high order of executive ability and business management.

Although the revenue of the station in 1911 reached over \$125,000, it was derived, except for the federal funds, from the earnings of the station in the laboratory and on the farm. By economy and good management Dr. Scovell had been able to save from these yearly earnings the funds needed for building up the physical equipment without calling on the State for aid.

He realized, however, that the State should make definite provision for the station, and one of the closing features of his career was securing from the legislature last winter a permanent appropriation of \$50,000 per annum for the use of the station in its experimental work and to provide for extension teaching. This was a notable achievement, and showed the confidence and support he had won from the people of the State. It placed the station in excellent financial condition, which would have enabled him in future to have focused his attention on the further development of the station along research lines. This development he had already set in motion, and his plans would soon have made the Kentucky Station conspicuous in that field.

To this extent, then, Dr. Scovell's greatest work was perhaps as an able administrative officer, a builder of public sentiment, a provider of opportunity for the work of others. But with a keen insight into the needs of the agriculture of the State he instituted and conducted personally experiments covering a wide range of subjects, including the culture and fertilizing of staple crops, the growing and curing of tobacco, and the handling of dairy cattle; and he planned for and directed the activities of the members of his staff along many important lines of experiment and inquiry.

This staff, of which he was the principal working member at the outset, had reached over thirty in number at the close of his career, all of whom devoted practically their entire attention to the station's work. His position as the leader of this group is well expressed in the appreciative resolutions of his coworkers, which declare that "to all of us he was not only the inspiring, helpful director, doing all in his power to stimulate and encourage and support the various departments of the station and the agricultural college, but more than all else the gentle, kindly, sympathetic friend."

With the reorganization of the State University in 1910, Dr. Scovell was urged to assume the direction of the college of agriculture, a task which his deep interest in the upbuilding of agriculture induced him to undertake in addition to his other duties. The progress of the new college of agriculture in two years has been most gratifying, and has reflected credit upon his organizing and administrative skill. Provision for its permanent maintenance, like that of the experiment station, came as one of the closing efforts of his life, the legislature of last year voting the university an appropria-

tion of \$50,000 per annum for maintenance, in which the college of agriculture is to share.

Dr. Scovell's activity was by no means confined to the duties of his own institution. He was an unusually public-spirited man, giving freely of his interest and his time to various local enterprises, and displaying a high order of ability in securing results. He was a leading spirit in the community, and one on whom much dependence was placed. In a national way he was prominently identified with the leading movements for agricultural advancement. From the time he came into the Association of American Agricultural Colleges and Experiment Stations in 1889 until the close of his life there was hardly a year when he did not serve the association in some capacity, either as an active officer or a member of one or more of its committees. He was a member of the executive committee from 1889 to 1895, and was secretary and treasurer from 1890 to 1894. He was president of the association in 1909, but was prevented by illness from presiding at the convention of that year.

His most conspicuous service was as chairman of a committee nominated by the association to supervise the tests of dairy cows at the World's Columbian Exposition, in 1893. This was one of the most remarkable breed tests ever conducted, being upon a scale and with a thoroughness never before approached. The management of the tests was practically in the hands of the committee, which developed methods and system, made a detailed record of the feed and of the performance of the individual cows, and computed the results. The records contained nearly three million separate entries of fact, and were deemed a very important contribution to the literature of dairying, but owing to the expense of their publication they were never printed in detail.

Much of the responsibility for the conduct of these tests with such thoroughness, fidelity, and skill naturally devolved upon the chairman of the committee, who was also called upon to handle many delicate matters in relations with the competing breeders and authorities. He gave to it much of his time and strength during a large part of the year, and the occasion was the beginning of the association of his name with dairy cattle in a national way. The success of the elaborate precautions adopted to secure absolute fairness and accuracy is attested by the fact that from no reputable source has the least doubt been cast upon the accuracy of the results.

Dr. Scovell's position as an expert in dairy cattle led him to be sought as manager of the Jersey herd at the St. Louis World's Fair test, and also to be offered the position of secretary of the American Jersey Cattle Club, both of which he declined. He was recently elected a director of the latter club. Less than two years ago he

rendered much assistance in establishing the Jersey herd of Elmen-dorf Farm, making a trip abroad for the purpose, and selecting high-priced animals in this country. He was also in demand as a judge at fairs. He loved dairy cattle, and his knowledge of them put him in the highest class of experts. The *Breeder's Gazette* says of him, "he was the best known and best liked judge of dairy cattle in America."

Dr. Scovell was also active for many years in the Association of Official Agricultural Chemists, in the development and improvement of methods of agricultural analysis. He was president of that association in 1909. He was for several years a member of the committee on food standards, which worked in cooperation with this Department after the passage of the Food and Drugs Act of 1906. He was a member of various learned societies, especially those relating to agriculture and to chemistry, and was a fellow of the American Association for the Advancement of Science.

Dr. Scovell's personal qualities deserve especially to be mentioned. Gentleness, kindness of heart, patience amounting almost to a fault, and a tolerance and sympathy which were never failing, were attributes which he embodied in remarkable degree. As his associates have well said, "in the highest and best sense he was the good citizen and the pioneer in the spread of a higher civilization and nobler ways of living." These high attributes of character, coupled with his unbounded good humor and cordiality, made him hosts of friends to whom he was joined by strong bonds of friendship.

The affection and esteem in which he was held in his home city is attested by the unusual action of the street railway company in ordering that at the hour of his funeral services every car should stop for three minutes, and of the mayor of Lexington in requesting that every wheel, on pleasure or business bent, should pay him the same mark of respect.

Truly, as President Barker of the university has said, "the world is richer because he has lived and poorer because he is dead."

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Physical chemistry and agriculture**, C. ULPANI (*Atti Soc. Ital. Prog. Sci. [Naples]*, 4 (1910), pp. 317-351, figs. 4; *abs. in Chem. Ztg.*, 35 (1911), No. 103, *Repert.*, p. 430).—The importance of the phase rule, electrolytic dissociation, colloidal condition, etc., for explaining some of the phenomena which occur in the soil, as well as the action of certain fertilizers, is pointed out.

**Agricultural chemistry**, F. KLINKERFUES (*Monatsh Landw.*, 4 (1911), No. 10, pp. 293-299).—This is a discussion of some of the newer findings in the field of agricultural chemistry.

**Phytin and phosphoric acid esters of inosit**, R. J. ANDERSON (*New York State Sta. Tech. Bul.* 19, pp. 3-16; *Jour. Biol. Chem.*, 11 (1912), No. 5, pp. 471-488).—Attempts to synthesize phytic acid and the hexaphosphoric-acid ester of inosit resulted negatively. The compound obtained with the Contardi method, or with a modification thereof, was the tetraphosphoric ester of inosit. It made very little difference whether the phosphoric acid was present in a small or large excess (above 6 molecules of phosphoric acid to 1 molecule of inosit), the same compound being produced. When present in a lesser amount than 6 molecules of acid to 1 of inosit a mixture of esters was obtained. The tetraphosphoric-acid ester of inosit, which is a new compound, could be easily isolated by means of its barium salt, and is very similar in appearance and in its behavior with reagents to phytic acid. When decomposed by heating with an acid, phosphoric acid and inosit were regenerated. The inosit used in the esterifications was prepared from a crude magnesium compound, which is mentioned below. Inosit was not so easily obtained as one is led to believe by the work of Starkenstein.

Several salts, tribarium phytate,  $C_6H_{12}O_9[(PO_3H)_2Ba]_3$ , pentabarium phytate,  $C_6H_{12}O_{27}P_6Ba_5$ , pentabarium ammonium phytate,  $C_6H_{12}O_{27}P_6Ba_5(NH_4)_2$ , pentamagnesium ammonium phytate,  $C_6H_{12}O_{27}P_6Mg_5(NH_4)_2$ , and tetracupric dicalcium phytate,  $C_6H_{12}O_{27}P_6Cu_4Ca_2$ , were prepared in some instances "from commercial phytin and from an organic-phosphorus magnesium compound by precipitating with barium chlorid and barium hydroxid; others were prepared from previously purified phytic acid." Those obtained from neutral or alkaline solutions have a general formula— $C_6H_{12}O_{27}P_6M_6$ . "The barium salt of phytic acid, obtained from very dilute hydrochloric acid or 10 per cent phytic acid solutions corresponds to the general formula— $C_6H_{12}O_{27}P_6M_5$ ." The constitution of phytin therefore still remains unsolved.

**Method for preparing tyrosin and glutaminic acid, and their quantitative determination**, E. ABDERHALDEN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 1, pp. 75, 76).—A quantitative method is described for preparing tyrosin and glutaminic acid, which allows the use of the mother liquors for isolating other amino acids which may be contained in them, as follows: The protein, i. e., waste silk, etc., is hydrolyzed by boiling for 6 hours with 3 times its bulk of fuming hydrochloric acid (specific gravity 1.19). The hydrolysate

is then evaporated repeatedly under diminished pressure to remove most of the hydrochloric acid, and the residue taken up with water. Ammonia gas is then passed through the solution until saturation has taken place, or if no ammonia bomb is at hand the residue is dissolved in an excess with ammonium hydroxid solution in water. The solution is then again evaporated to dryness, and if silk waste was employed the solution is extracted with cold water. Tyrosin remains in the residue. A still better way is to boil the residue with water containing some animal charcoal, the tyrosin being allowed to crystallize out from the extract. The mother liquors obtained are then evaporated to dryness and esterified in the usual manner. The undissolved ammonium chlorid may be filtered off, while the remainder of the process is the usual one.

For preparing the glutaminic acid ammonia gas is passed through the aqueous solutions and these evaporated to dryness. The residue is then recrystallized from hot water. The greater portion of the glutaminic acid can be obtained by fractional crystallization, and the remainder from the mother liquors by precipitation with alcohol.

The identity of the guanin pentosid prepared from molasses with reference to vernin, E. SCHULZE and G. TRIER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 2-3, pp. 145-147; *abs. in Zentbl. Biochem. u. Biophys.*, 12 (1912), No. 23, p. 901; *Zentbl. Physiol.*, 26 (1912), No. 1, p. 9).—The guanin pentosid obtained by Andrlík (E. S. R., 26, p. 116) from molasses residues is thought to be identical with the compound known as vernin. The authors believe that guanin-*d*-ribose is the only guanin pentosid occurring in nature.

The complete extraction of alcohol and water-soluble phosphorus compounds from plants, H. ULRICH (*Arch. Expt. Path. u. Pharmacol.*, 68 (1912), No. 3, pp. 171-185).—The 3 principal groups of phosphatids can be extracted by treating the dried plant tissue, etc., 24 hours with absolute alcohol, being careful to exclude all extraneous moisture during the process. This is followed by extracting the material with dilute nitric acid (0.5 per cent) for about 20 successive times at room temperature. The work was done with oats and wheat bran.

The mode of action of phosphatase, I, H. EULER and S. KULLBERG (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 74 (1911), No. 1, pp. 15-28).—The enzym phosphatase (the authors propose using the termination "ese" for synthesizing enzymes), in the presence of phosphates during the fermentation of sucrose with yeast juice or with extract of dried yeast will bring about the formation of carbohydrate-phosphoric acid esters. The authors now find that this enzym is much more readily absorbed by kaolin than was invertase from a neutral solution, and is much more quickly destroyed by precipitating with alcohol. Phosphatase shows its greatest activity in alkaline solutions, and at 30° C. its activity is one and three-fourths times greater than at 20°, but it is much less resistant to heat than invertase. It was also noted that unaltered dextrose does not react, or only very slowly reacts with the phosphate.

An ester obtained by treating a partially fermented solution of dextrose or levulose with a phosphate was optically inactive, nor was an optically active product obtained when the ester was decomposed with an acid or alkali. The ester is in all probability produced from a substance which is formed and decomposed again during the action of yeast on dextrose. This holds good for levulose and sucrose also. *Aspergillus niger* (when cultivated in sucrose and yeast water) and ripe oats contain phosphatase. Two enzymes are apparently concerned in the above process, one which converts the sugar into an ester-forming carbohydrate, and another which synthesizes the ester from the phosphate and carbohydrate ions.

In regard to the action of phosphatase, H. EULER and S. KULLBERG (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 2-3, p. 241; *abs. in Zentbl. Expt. Med.*, 1 (1912), No. 4, p. 153).—The difference in results obtained by von Lebedew and the authors can be attributed to the kind of yeast preparation employed.

Regulatory formation of the enzym tannase, L. KNUDSON (*Abs. in Science, n. ser.*, 34 (1911), No. 868, pp. 219, 220).—*Aspergillus niger* was grown in 14 media, each of which contained a different carbon compound. The results show that tannase formation takes place when the sugar in the medium is displaced by tannic or gallic acid, or supplemented by tannic acid. Gallic acid was found not to be as efficient as tannic acid as a source of carbon for stimulating the formation of the enzym.

As no work has been reported on the effect of concentration of the transformable substance on the quantity of the corresponding enzym produced, the author made tests with *A. niger* and *Penicillium* sp., "in which a modified Czapek's solution was the nutrient medium—in this the concentration of sugar was made 10 per cent, and it was supplemented by tannic acid in concentrations varying from 0.01 to 10 per cent. The quantity of the enzym produced was augmented by increase in concentration of the tannic acid. None, however, was formed when the concentration of tannic acid was as low as 0.01 per cent.

"Similar results were obtained with *Penicillium* sp., *A. candidus*, *A. oryzae*, and *P. granulatum* cultivated in a synthetic solution in which the carbon was supplied as 5 per cent cane sugar and supplemented by 2 per cent tannic acid also developed in the enzym tannase. *P. expansum* in a similar solution did not develop the enzym."

Separation of peroxidase from catalase, A. KASANSKI (*Biochem. Ztschr.*, 39 (1912), No. 1-2, pp. 64-72).—This is a study of a method for obtaining preparations which will give the peroxidase reaction but not the catalase test. It is accomplished by adding pyrogallol to the material under examination. Hemp, sunflower, and barley seedlings, liver, radishes, horseradish, and yeast were studied.

Action of emulsin upon salicin in an alcoholic medium, E. BOURQUELOT and M. BRIDEL (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 15, pp. 944-946).—The results show that the action of emulsin upon salicin is not arrested in solutions containing strong concentrations of alcohol.

The calcium carbide method for determining moisture, H. C. MCNEIL (*U. S. Dept. Agr., Bur. Chem. Circ.* 97, pp. 8, fig. 1).—This is a description of a method for determining moisture in paints, soaps, and miscellaneous materials by the calcium carbide method (*E. S. R.*, 27, p. 312). Calcium carbide is added directly to a known weight of the sample, the amount of acetylene generated during the process measured, and the amount of acetylene found is then referred back to moisture.

The apparatus employed in the method is illustrated and consists of a generating flask of about 20 cc. capacity for holding a known weight of the material to be examined, and which has a carbide tube with a projection on one side for holding 5 cc. or more of a finely powdered carbide. The flask is attached to a 100 cc. jacketed burette, drawn out at the ends to facilitate connections. The jacket is connected with a tap for the purpose of cooling with water and to obtain an accurate control of the temperature. In addition there is a leveling vessel. The liquid used in the gas burette and leveling vessel is either mercury or a concentrated solution of sodium chloride, which has stood in contact with acetylene until saturation has taken place. The latter solution is tinted with phenolphthalein and a little sodium hydroxide to facilitate reading.

The behavior of this method with soaps, paint materials, infant foods, leather powders, vanilla beans, lubricating oil, and flour is described in detail.

**The Kjeldahl method**, M. SIEGFRIED and O. WEIDENHAUPT (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 76 (1912), No. 2-3, pp. 238-240; *abs. in Zentbl. Expt. Med.*, 1 (1912), No. 6, p. 242).—Boiling should not be resorted to after potassium permanganate has been added to the solution. The author takes the flask from the burner or turns the burner out, adds permanganate, heats, and then adds permanganate again for a period of 3 minutes until the pink color remains permanently.

**A practical method for reducing potassium platonic chlorid when determining potash as potassium platonic chlorid**, A. FIECHTER (*Ztschr. Analyt. Chem.*, 50 (1911), No. 10, pp. 629-632).—The process consists of adding some magnesium filings or chips in dilute hydrochloric acid to the potassium platonic chlorid, which has been previously washed with alcohol and dissolved in a little hot water. The process is completed in a few minutes if the mixture is heated on a wire gauze. Some comparative tests between the method and Neubauer's show a difference of only from 0.1 to 0.2 per cent.

**The determination of potassium as potassium platonic chlorid**, B. TRNKA (*Ztschr. Analyt. Chem.*, 51 (1912), No. 2, p. 163).—A discussion in regard to priority of the method described by Fiechter above.

**In regard to iron metabolism**.—I. Method for the quantitative determination of small amounts of iron, F. JAHN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 75 (1911), No. 4, pp. 308-338; *abs. in Zentbl. Biochem. u. Biophys.*, 12 (1912), No. 21-22, p. 863).—For determining iron in organic substances, especially in small amounts, the author utilizes the Knecht and Hibbert method, which rests on the following equation:  $\text{FeCl}_3 + \text{TiCl}_3 = \text{TiCl}_4 + \text{FeCl}_2$ . The method gives results which differentiate amounts of 0.1 mg. of iron very definitely and allows the titration to be done in 15 minutes.

The substances required in the test are concentrated sulphuric acid and nitric acid of known iron content for ashing according to the Neumann method, a solution of potassium sulphocyanate, approximately 40 per cent strength, a 1/250-normal to 1/500-normal titanous trichlorid solution, which is preserved by pouring paraffin oil upon it, a ferric sulphate solution containing 1 mg. of iron per liter, and air-free water.

**A modification of Marsh's apparatus for the detection of arsenic**, L. COHEN (*Dept. Agr. N. S. Wales, Sci. Bul.* 4, 1911, pp. 5, fig. 1).—The following modification of Marsh's apparatus, as used by the author, is described:

"Impure hydrogen, generated from dilute sulphuric acid and ordinary granulated commercial zinc, is purified by passing through a neutral aqueous solution of silver nitrate, which combines with the  $\text{AsH}_3$  with reduction to metallic silver. It then passes through a mixture of the suspected liquid with dilute sulphuric acid, in contact with a small quantity of pure arsenic-free zinc, or a bundle of magnesium wire (in which latter case the solution must contain only very little free acid, so as to avoid much heating), and carries over the small quantity of hydrogen thus produced, with the  $\text{AsH}_3$  resulting from the reduction of any arsenic present in the suspected matter. The combined gases, after drying, are tested in the usual way."

**The chemical composition of the clay obtained in the Schloesing-Grandeau method**, E. BLANCK (*Jour. Landw.*, 60 (1912), No. 1, pp. 75-81).—The results of examining the clays elutriated by the Schloesing-Grandeau method from 7 Silesian soils, taken chiefly in the vicinity of Breslau, Germany, are given. The conclusion is reached that the chemical composition of the clay varies markedly, but within certain limits, and furthermore that the chemical compo-

sition of these clays bears no relation to the chemical composition of kaolin, because much of it consists of quartz particles. The claim made for the uniformity of these products obtained by this method is, therefore, not justified.

In regard to a precipitin with which it is possible to differentiate boiled insoluble protein, W. A. SCHMIDT (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, *Orig.*, 13 (1912), No. 2, pp. 166-185).—Blood serum heated for 30 minutes at a temperature of 76° C., then treated with dilute sodium hydrate, and heated for 15 to 20 minutes more in order to make it nonreacting to either native or heat precipitin, when injected into an animal will yield a serum which contains a heat-alkaline-protein precipitin. This serum will react with a serum which has been boiled for 3 hours and dissolved in a decinormal sodium hydrate solution. The serum is a positive test for differentiating insoluble proteins.

In regard to the utility of the ester method for detecting monoamino acids when polypeptids are present, E. ABDERHALDEN and R. HANSLIAN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 4, pp. 285-288).—The method is deemed perfectly reliable for this purpose, providing the necessary precautions are taken.

A comparative study of some analytic methods for determining phosphorus in vegetable products, A. PONTE (*Staz. Sper. Agr. Ital.*, 44 (1911), No. 5-6, pp. 459-461).—Comparing the results obtained for phosphorus when incinerating by the ordinary ashing and the electrical methods (E. S. R., 20, p. 207), it is noted that the former has losses which vary between 2 and 11 per cent. The methods which incinerate in the presence of calcium oxid yield figures about similar to those obtained with the electrical method.

The ash of vinegar, R. E. REMINGTON (*North Dakota Sta. Spec. Bul.*, 2 (1912), No. 5, pp. 92-94).—In determining the phosphoric acid content of vinegar considerable difficulty was always experienced in obtaining duplicate results for the soluble and insoluble portion, although concordant results for total phosphoric acid were practically always obtained. In order to determine if the method of ashing used was accountable for these variations, 3 samples of cider vinegar were ashed in platinum dishes over Bunsen burners, which in each case were adjusted to give various degrees of heat. Some of the samples were finished with a blast lamp.

"While the temperature seems to exert little or no influence upon the total amount of phosphoric acid recovered, in all cases the soluble portion increases with increasing temperature. Expecting that higher temperature would favor the formation of more or less insoluble pyrophosphates, the results obtained are surprising. The alkalinity of the soluble ash increases with the temperature so long as it does not rise above the fusing point of the ash. But when the blast lamp was used, a decrease in alkalinity was noted, due to the loss of potassium salts by volatilization. That this is so was shown by ashing duplicate portions of vinegar, in one case blasting only long enough to obtain complete fusion, in the other for 30 minutes. . . . If the ash data are to continue of value in the interpretation of vinegar analysis, the ashing must be done under more carefully specified conditions than heretofore—say in an electric muffle, with accurate temperature control and for a definite time. Otherwise no two chemists can expect to obtain concordant results."

The Fiehe reaction for the examination of honey, L. STÖCKLIN (*Ann Falsif.*, 5 (1912), No. 41, pp. 116-121).—This is a discussion of the reasons for some of the failures obtained with the Fiehe reaction, and a description of a procedure which will give better results.

The occurrence of boric acid in honey, G. BÜTTNER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 23 (1912), No. 4, pp. 139, 140).—Pure honey often contains boric acid.

**Detection of nitric acid in watered fruit juices.** R. COHN (*Ztschr. Öffentl. Chem.*, 17 (1911), No. 19, pp. 361-363; *abs. in Analyst*, 37 (1912), No. 439, p. 21).—The method is as follows: Make 75 cc. of the juice alkaline with sodium hydroxide, evaporate nearly to dryness, and extract the residue with alcohol at a temperature of 40° C. The extraction is conducted for several minutes. If the residue from the alcohol extract still has a sirupy appearance it must be re-extracted with alcohol, and then taken up with 10 cc. of water and tested with diphenylamin for nitric acid. No positive reaction was ever obtained with authentic raspberry, currant, or cherry juices. Bilberry juice was found to give a blue coloration with sulphuric acid alone, and therefore can not be tested by this method. Nitron can be employed for this purpose.

**Methods for sugar analysis and allied determinations.** A. GIVEN (*Philadelphia*, 1912, pp. 75, figs. 8).—This is a description of methods for examining sugar and sugar products. The official methods are included and some apparatus used in the Bureau of Chemistry of this Department is pictured.

**Examination of lactose and the by-products of lactose manufacture.** A. BURR and F. M. BERBERICH (*Chem. Ztg.*, 35 (1911), Nos. 82, pp. 751, 752; 86, pp. 794-796; 87, pp. 893, 894).—Previously noted from another source (E. S. R., 26, p. 313).

**The chemical and bacteriological methods for examining milk.** G. RÜHM (*Ztschr. Fleisch u. Milchhyg.*, 22 (1912), No. 5, pp. 142-148).—This continuation of work previously noted (E. S. R., 25, p. 207) deals entirely with bacteriological methods. It includes some special methods for detecting and differentiating the organisms involved in mastitis, pyogenic infections, and actinomycosis.

**What is the best test for judging the quality of milk?** J. STAPENSÉA (*Tijdschr. Veeartsenijk.*, 39 (1912), No. 6, pp. 231-260).—This is a study of the various methods proposed for examining milk from the hygienic point of view.

The catalase test is given first place for detecting milks which contain secretions from animals affected with mastitis. If a milk yields a volume of gas of 2 cc. or more within 3 hours, at a temperature of 37° C.±, the sample should be tested by the Trommsdorff leucocyte method and its chlorine content determined. When necessary other tests, such as Schardinger's reaction and the diastase test, may be employed in addition. The relation of the bacterial content of the milk to these reactions is also considered.

**Methods for determining iron in milk.** F. E. NÖTTBOHM and W. WEISSWANGE (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 23 (1912), No. 10, pp. 514-523).—This work, which was done in part with synthetic ash solutions, confirms the findings of others that the iron content of milk can not be determined in a hydrochloric solution of the milk ash by the colorimetric method.

On the basis of the results obtained the authors recommend the following method for determining the iron content of milk: One hundred cc. of milk is dried in 2 platinum dishes on the water bath, heated to from 150 to 180° C., and ashed in a quartz muffle. The process is then completed over a microburner. In order to remove the last traces of carbon the ash is rubbed up with water, dried, and ashed again. The white ash is now mixed with iron-free hydrochloric acid and evaporated to dryness, and this process is repeated. The ash is then taken up with 40 cc. of  $\frac{1}{2}$ -normal hydrochloric acid solution, transferred to an Erlenmeyer flask and oxidized by the addition of a few drops of nitric acid.

After cooling the ash solution it is transferred to a separatory funnel, 2 cc. of a 5 per cent solution of "cupferron" added, mixed well, and allowed to stand for  $\frac{1}{4}$  hour. The solution is shaken out twice with 25 cc. of chloroform, the chloroform extracts are transferred to a 100 cc. Erlenmeyer-Jena flask, and the chloroform distilled off on a water bath, care being taken to distill off the last

traces of chloroform. The residue is ashed by carefully heating the flask over a free flame. The iron oxid obtained is dissolved in hydrochloric acid and determined colorimetrically with potassium sulphocyanate.

**The iron content of cow's milk.** F. EDELSTEIN and F. VON CSONKA (*Biochem. Ztschr.*, 38 (1912), No. 1-2, pp. 14-22).—Cow's milk collected in glass vessels was found to contain from 0.4 to 0.7 mg. of iron per liter, with an average of 0.5 mg. In ordinary mixed dairy or market milk the amount was somewhat higher, varying from 0.7 to 0.15 mg. The amount of iron in milk depends very much on the methods of handling it in the dairy and subsequently, and this may explain the great discrepancies in regard to the iron content of milk noted in the literature. Woman's milk contains about one-third to one-fourth more iron.

The Neumann iodometric method and the Lachs-Friedenthal method (E. S. R., 26, p. 314) were employed in this work. Certain disadvantages of the latter method are pointed out.

**Notes on the analysis of margarin.** C. H. CRIBB and P. A. E. RICHARDS (*Analyst*, 36 (1911), No. 424, pp. 327-333).—The simple Reichert-Wollny refractometer test, according to these authors, is no longer effective for determining whether margarin comes up to the legal standard, particularly where coconut oil and butter are present. A combination of the Wollny process and the Polenske method is suggested for the examination of butter, margarin, etc.

The authors propose a correction of the volatile fatty acids to include those due to coconut oil and for the solubility of so-called insoluble fatty acids. Experiments are reported with mixtures of coconut oil, butter fat, and margarin fat to illustrate some of the contentions noted above.

**Time required to sterilize canned goods at different temperatures.** H. SERGER (*Konserv. Ztg.*, 13 (1912), No. 12, pp. 89, 90; *Pure Products*, 8 (1912), No. 5, pp. 257-260).—From figures obtained in experimental tests the author proposes to subtract 60 minutes from the time required to sterilize the material in an open water bath and to divide the remainder by 3, the result obtained approximating the actual time required in heating in a retort. Conversely, the time actually required in a retort may be multiplied by 3 and 60 minutes added to obtain the time required in an open water bath. Carrots and snap beans were computed to need 16.6 and 20 minutes, respectively, in a retort, and Brussels sprouts, asparagus, and peas 183, 87, and 108 minutes in an open water bath.

"These figures are naturally not strictly exact, but are approximately correct, and will be the maximum times required, since we are considering the case of *Bacillus subtilis*, which is the most resistant of bacteria. Those who contemplate changing from the open water baths to retorts, or vice versa, will find this method of calculation of use."

**The preparation of berry and other fruit wines.** P. ARAUNER (*Naturw. Wchnschr.*, 27 (1912), No. 19, pp. 301, 302).—The preparation of apple, gooseberry, strawberry, blackberry, currant, raspberry, blueberry, pear, cherry, and plum wine with pure culture yeast is described.

**The milling of cane considered in relation to the volume occupied by the fiber.** N. DEERR (*Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul.* 38, pp. 61, figs. 24).—According to the author, no experiments are on record which show how cane fiber behaves under pressure. It was thought that if this topic were studied some data might be obtained in regard to the weight of the juice expressed and the volume of the fiber corresponding to a definite pressure.

"The amount of juice expressed from chopped cane subjected to a direct pressure increases with the degree of fineness of the material. After chopped cane has been pressed to a certain pressure a further notable quantity of juice can be obtained by releasing the residue from pressure and pressing again. The pressure at which juice begins to flow from bagasse is not a measure of the

pressure at which it has been pressed. With the pressure remaining constant greater percentages of juice are obtained from chopped cane as the quantity of material under pressure decreases. . . . At pressures up to 60 lbs. per square inch the volume of bagasse varies inversely as the 2.5th root of the pressure."

The work shows that "the pressure exerted by the bagasse in its passage between the top and front roller is very much less—probably about one-fortieth—than that exerted in its passage between the top and back roller, that is to say, the strains in the conventional 3-roller mill are symmetrical and as much metal is used in the feed side and in the front roller as in the delivery side and in the back roller. The logical application of the experiments described here would indicate that the front roller be regarded solely as a feed roller and would point to a 2-roller mill with a small feed roller as being the rational design for the later mills of a train.

"In a 2-roller mill, however, the pressure exerted by the layer of bagasse will not be in a vertical line but . . . will pass through a point 0.81 in. from the line of nearest approach of the rollers; in a mill with rollers superimposed vertically there will then be a small side thrust, due to the slow recovery of bagasse after compression."

Stohmann's handbook of sugar manufacture, revised by A. SCHANDER (*Stohmann's Handbuch der Zuckerfabrikation*, Berlin, 1912, 5. ed. rev., pp. XVIII+810, pl. 1, figs. 384).—A fifth edition of this well known work.

Centenary of the manufacture of beet sugar, 1812-1912, L. LANDET (*Bul. Assoc. Chim. Sucr. et Distill.*, 29 (1912), No. 9, pp. 600-619).—This is a detailed historical discussion of the numerous events which occurred in the beet-sugar refining industry during the years 1812-1912.

Thirty-fourth report of the Swiss Agricultural-Chemical Institute at Zurich, 1911 (*Landw. Jahrb. Schweiz*, 26 (1912), No. 3, pp. 167-182).—This report contains analyses of fertilizers, feed stuffs, agricultural products, and miscellaneous substances.

## METEOROLOGY—WATER.

Weather and agriculture, A. SCHMAYSS (*Landw. Hefte*, 1912, No. 7, pp. 36, figs. 7).—The farmer as a weather observer and prognosticator, the signs and methods he makes use of, and means of improving his methods by use of the weather maps and application of scientific principles, are discussed. Predictions based on phases of the moon as well as on the 100-year calendar of Mauritius Knauer and many popular rules are shown to be of no value. Lists of books suitable for the German farmer's use and of weather service stations in Germany are given.

Monthly Weather Review (*Mo. Weather Rev.*, 40 (1912), Nos. 3, pp. 321-486, pls. 10; 4, pp. 487-658, pls. 10, figs. 3).—In addition to the usual climatological summaries, lake levels, weather forecasts and warnings for March and April, 1912, notes on the application of upper-air observations to weather forecasting, March and April, 1912, river and flood observations, lists of additions to the Weather Bureau library and of recent papers bearing on meteorology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 3.—Some Effects of Air Drainage in River Valleys, by J. R. Weeks; The Brevoort Bluff Tornado of February 21, 1912, by J. H. Kimball; The Floods of March, 1912, in the South Atlantic and East Gulf States, by C. F. von Herrmann; Ice Storm in Illinois, by C. J. Root; Abnormal Snowfall at Springfield, Mo., by J. S. Hazen; Temperatures Injurious to Peaches, Apples, and Pears in Various Stages of Development (see page 439); Depth of Snow in the

Mountains of Utah at the Close of March, 1912, by A. H. Thiessen; Report of Snow Measurements in Maple Creek Watershed, Utah County, Utah, March 4 to March 14, 1912, by A. H. Thiessen; Notes on the Rivers of the Sacramento and San Joaquin Watersheds during March, 1912, by N. R. Taylor; Notes on the Streams of the Upper San Joaquin Watershed, by W. E. Bonnett; Weather Conditions at Los Angeles, Cal., by A. B. Wollaber; and The Severe Cold of December 25-26, 1911, in the Citrus Districts of Southern California, and Methods Adopted for Fruit Protection, by A. B. Wollaber.

No. 4.—Destructive [Wind] Storm of April 2, 1912; The Floods of April, 1912, in the Gulf States; Floods in Michigan, Spring of 1912, by C. F. Schneider; Tornadoic Storms in Illinois, by C. J. Root; Tornado at Murphysboro and Bush, Ill., April 21, 1912, by F. H. Colyer; Tornado Near Carbondale, Ill., by F. H. Colyer; City and Suburban Temperatures, by E. D. Coberly; Does Frost Fighting Pay in Utah? by J. C. Alter; Why the Snow Slides from the Mountain Slopes, by J. C. Alter; Measurement of Snow in Big Cottonwood Canyon, Utah (illus.), by S. Q. Cannon; Notes on the Rivers of the Sacramento and San Joaquin Valleys for April, 1912, by N. R. Taylor; Notes on the Streams of the Upper San Joaquin Watershed, by W. E. Bonnett; New Heater and Vaporizer for Frost Protection, by A. G. McAdie (see page 439); Lower Powder Valley Project, Baker County, Oreg., by J. H. Lewis; Reorganization of Government Meteorological Work in Chile; and A Peculiar Stroke of Lightning (illus.), by N. N. Mason.

General weather review, 1910-11, W. M. ESTEN and C. J. MASON (*Connecticut Storrs Sta. Rpt. 1910-11, pp. 579-597, figs. 2*).—A record is given of observations on temperature and precipitation during each month of 1910 and 1911 at Storrs, the rainfall for 1910 and 1911, the monthly mean temperature and monthly precipitation for the 23 years, 1888 to 1910, and dates of the last and first killing frosts for the 24 years, 1888 to 1911. The mean temperature at Storrs during the 24 years has been 47.1° F., the highest 99°, and the lowest -14°. The mean annual rainfall has been 45.35 in., the longest growing season 184 days, and the shortest 131, the average date of the last killing frost in the spring, May 4, and of the first killing frost in the autumn October 8.

Meteorological observations (*Maine Sta. Bul. 197, pp. 329-331*).—Observations at Orono, Me., on temperature, precipitation, cloudiness, and wind during 1911 are compared with the means of similar observations for 43 years. The mean temperature for 1911 was 43.62° F., the mean for 43 years 42.39°; the precipitation for 1911 was 36.06 in., for 43 years 43.30 in.; the snowfall for 1911, 76.25 in., for 43 years 91.11 in.; the number of clear days in 1911 was 113, cloudy days 133; total movement of wind in miles, 54,526. A table is also given which shows the monthly and annual precipitation during 1911 at 18 different places in Maine.

Report of the meteorologist, F. STOCKTON (*New Mexico Sta. Rpt. 1911, pp. 50-55*).—Summaries of observations at the station from 1905 to 1911 on temperature, precipitation, and dates of first and last killing frosts, and from 1906 to 1911 on storms and wind movement are given.

[Meteorology of Finland] (*Fennia; Bul. Soc. Géogr. Finlande, 30 (1911), pts. 1, Cartes 16-19, pp. 62, figs. 3; 3. Cartes 16-19*).—The meteorological and climatological conditions of Finland are shown in a series of charts which are briefly discussed. A bibliography of the more important literature on the subject is given.

“Red rain” dust, T. STEEL (*Chem. News, 105 (1912), No. 2742, p. 282*).—An analysis of dust which fell in Sidney October 11, 1909, is reported, indicating the material to be mainly sand and clay with 0.22 per cent phosphoric acid

and 0.17 per cent nitrogen. Potash was not determined. Other papers on the subject are reviewed.

**Predicting water supply for the farmer, J. C. ALTER** (*Sci. Amer. Sup.*, 73 (1912), No. 1904, pp. 413, 414, figs. 5).—A brief account is given of a snow survey of the Maple Creek watershed near Springfield, Utah, by the Weather Bureau of this Department.

"The actual work of the snow survey consisted in going up the bottom of each gulch or canyon and back and forth along the slopes, measuring the snow depth and density every thousand feet or so, depending upon the variability of the snow deposit, the general topography, and the brush or forest cover, and mapping the snow area on a field map. . . .

"Stream flow measurements at a weir, located some distance above the highest farm land, have been made daily since the completion of the survey, and will be continued throughout this year (1912) and probably indefinitely in the future. Rain and snowfall observations have also been made from a precipitation gage located near the weir, and are to be continued indefinitely.

"The first year's records of run-off, following the survey, are not directly comparable with the amount of water in the form of snow, shown by the survey, even when corrected for precipitation gain, and evaporation loss, as there is a seepage loss in this particular canyon, the amount of which can not be determined from one year's observations."

### SOILS—FERTILIZERS.

**Investigations on soils from crystalline rocks in process of weathering, K. BUSCH** (*Untersuchungen über Verwitterungsböden kristallinischer Gesteine. Inaug. Diss., Univ. Halle, 1911, pp. 67; Kühn Arch., 1 (1911), pt. 2, pp. 357-389, fig. 1; abs. in Zentbl. Agr. Chem., 41 (1912), No. 3, pp. 145-147*).—It is pointed out that previous investigations on soil particles, such as those by Ramann, Keilhack, Meyer, Sachse, Borzuchowski, and Puchner, have had to do with soil material of a heterogeneous character. In his work, therefore, the author used soils derived from known sources, that is, those formed in place from diabase, granite, and basalt rocks. With them he studied (1) the relation between the mechanical composition as determined by Hilgard's elutriator method and the hygroscopicity of the soil by the Mitscherlich method (E. S. R., 24, p. 419), and (2) the proportion of plant-food constituents contained in the different sized groups of soil particles. The surface soil derived from the diabase rock was a porous, fertile loam with a very porous, slightly sandy subsoil. The granite soil was a shallow, sandy loam with a rocky subsoil, and the basalt soil was a deep, heavy loam.

It was found that the individual soil particles of the different groups as separated out by sedimentation were not of the same size. This the author attributes to a difference in the surface area of the particles and a consequent variation in the resistance to the current of water. The variation in results of repeated mechanical analyses of the same soil is attributed to errors in sampling. Contrary to the conclusions of Mitscherlich, the hygroscopicity of these soils was not found to be proportional to the outer surface area. This may be explained by the fact that the larger soil particles contained hygroscopic water in the weathered cracks and crevices. Soils of the same mechanical composition differed in their hygroscopicity, this difference being determined by the mineral composition and the stage of weathering of the soil.

A relation between the size of the soil particles and the plant-food constituents was determined only for the iron and the calcium and magnesium carbonates. The iron was associated mostly with the finest particles. The dis-

tribution of the calcium and magnesium carbonates in these soils was similar to that in soils derived from marls, that is, the percentage of these constituents was higher for the finer particles and decreased in the sand components of the soil. There was no relation between the total lime, magnesia, phosphoric acid, potash, and nitrogen contents and the size of the soil particles. The amount of these constituents in the individual groups of soil particles was found to be dependent entirely upon the mineral composition of the soil particles which go to make up the individual groups.

It was also found that the solubility of phosphoric acid, calcium, and magnesium of the diabase subsoil in hydrochloric acid was greater than that of the surface soil. This was thought to be due to the more advanced weathering of the subsoil.

**Gray sand and hardpan (Ortstein),** WILHELM GRAF ZU LEININGEN (*Abhandl. Naturhist. Gesell. Nürnberg, 19 (1911), No. 1, pp. V+45, fig. 1; abs. in Internat. Mitt. Bodenk., 1 (1912), No. 6, pp. 584, 585*).—This report contains a review of the literature and an account of the author's own contributions to the subject. It is shown that hardness of hardpan is not dependent upon the iron compounds it contains but seems to be closely related to the moisture content of the soil. The aeration of the soil also seems to prevent the extreme hardening of the hardpan formation.

It is held that no one theory regarding the formation of hardpan has general application since the conditions of formation vary with the locality, especially with the kinds of vegetation and climatic conditions. Ortstein is rich in alumina and phosphoric acid and poor in lime, magnesia, and potash. Diluvial gray sand is, as a rule, poor in plant-food constituents. It may, however, be more fertile when the soil is formed in place. As a rule, the absorptive capacity of gray sand is low. Ortstein is not associated with any definite formation, although it generally occurs in fertile, loose sands and also on granites and buntersandstein. It is seldom formed in lime and gneiss soils. The age of ortstein has been determined in one case to be over 2,000 years.

Regarding brown soils, K. D. GLINKA (*Pochvovūdnĕie (Pédologie), 13 (1911), No. 1, pp. 17-48; abs. in Internat. Mitt. Bodenk., 1 (1912), No. 6, pp. 578-580*).—The author reports a study of typical formations of the so-called brown soils of central Europe as compared with similar formations (podzol soils) in Russia. It is stated that these brown soils are in a less advanced state of "podzolization" (chemical leaching processes under the influence of the solvent action of humus acids) than those of Russia, which are not of a typical brown type.

A geological sketch showing the distribution of the brown soils in Europe and in Asia is included.

**Unproductive black soils,** S. D. CONNER and J. B. ABBOTT (*Indiana Sta. Bul. 157, pp. 235-264, figs. 5*).—It is stated that Indiana contains, principally in the northwestern counties, several hundred thousand acres of black or peat soils which are more or less unproductive but capable of being made fertile and productive by drainage and fertilization. Cooperative experiments were, therefore, undertaken on this soil in different counties to test the value of various fertilizer materials and mixtures for its improvement. Chemical analyses of samples of the soil are also reported.

The results showed that these soils were more often deficient in potash than in any other element and that applications of potash gave decided profit. "Some black soils of Indiana are more or less acid. Where there is strong acidity some form of basic lime, such as pulverized limestone, should be applied. On acid soils phosphoric acid is almost always needed in addition to limestone.

Potash is usually a secondary need on such soils." All the soils were well supplied with organic matter and only in a few cases was nitrogen necessary.

The soils of Alabama and their adaptations to crops, J. F. DUGGAR (In *Alabama's New Era. Montgomery: State Immigr. Dept. [1911], pp. 39-47, pl. 1*).—This is a general description of the physiographic divisions of Alabama and their characteristic soils and crop adaptations.

"Taking the State of Alabama as a whole, it may be said that sandy soils cover a larger area than do either clay loams or clays and that the largest areas of clay soils are in the central prairie regions and in the Appalachian Valley and Piedmont Region, in the eastern part of the State. The greater part of the surface of Alabama is slightly rolling, but there are broken or mountainous areas as well as comparatively level land. The largest areas of nearly level land are (1) in the southern edge of the Coastal Plain, that is, in the quarter of the State nearest to the Gulf; (2) in the Central Prairie Region and adjacent narrow regions on each side of it; and (3) in the Tennessee Valley. By far the greater proportion of the cultivated land of Alabama is free from stones, but the presence of stones, especially in the Piedmont Region, in the region of gravelly hills, and elsewhere, does not decrease productiveness, though the stones interfere with the convenience of cultivation."

[Analyses of soils of the Burirhat Station Farm] (*Ann. Rpt. Agr. Stas. East Bengal and Assam, 1911, pp. 25-28, pl. 1*).—Chemical analyses of samples of soil from fertile and from barren areas on this farm showed very little difference in composition except that the calcium carbonate content in the samples of fertile soil was about twice that in the samples of barren soil. The ratio of magnesia to lime was high in both cases, being generally in the proportion of 3 or 4 to 1. Experiments to determine the effect of liming the soil for its improvement are now in progress.

Weeds in relation to soils, WINIFRED E. BRENCHLEY (*Jour. Bd. Agr. [London], 19 (1912), No. 1, pp. 20-26*).—These studies have been previously noted (E. S. R., 27, p. 29).

The chemical characterization of soils, E. J. RUSSELL (*Chem. World, 1 (1912), No. 1, pp. 5-8, figs. 3*).—From a consideration of factors which influence the availability of plant-food constituents of the soil the author concludes "that for a complete account of the fertility relationships of soils a chemical examination alone is not likely to lead to any useful result." It is shown that soils of identical composition as determined by ordinary methods of soil analysis vary widely in productiveness as a result of difference in water conditions, suitability of the organic matter to support active bacterial life, and various other factors. Ordinary analysis must therefore be supplemented by various other inquiries before advice regarding improvement of a soil can safely be given.

More recent investigations in soil science, ALBERT (*Ztschr. Forst. u. Jagdw., 44 (1912), No. 4, pp. 240-249*).—The author reviews the development of studies in colloid chemistry, pointing out particularly the application of this subject to the study of the soil. He is of the opinion that the colloid theory is often used to explain hitherto unsolved problems of physics and chemistry without exact knowledge of the scientific basis upon which it rests. There is need of a more careful and extended study of the subject.

A short bibliography is added.

Colloid chemistry studies on humus in limed and unlimed soils, W. THAER (*Jour. Landw., 60 (1912), No. 1, pp. 1-18; abs. in Chem. Abs., 6 (1912), No. 13, p. 1797*).—This is an extract from a dissertation which has already been noted (E. S. R., 25, p. 823). Preliminary studies of the chemical composition and

other properties of products obtained by extracting limed and unlimed compost with water, precipitating with alcohol, and dialyzing the products are reported.

The concentration of phosphoric acid in the soil in the neighborhood of old centers of population, F. HUGHES and A. ALADJEM (*Agr. Jour. Egypt*, 1 (1912), No. 2, pp. 81-83).—Analyses of soil samples from the "Kom" of Sakha showed a much higher phosphoric acid content than the soils of the Delta of Egypt as a whole. It is stated that this "Kom" marks the site of one of the oldest cities of the Delta, and that the accumulation of phosphoric acid is a "clear case of valuable plant food being drawn from a large area and becoming concentrated in the course of time over an area much smaller and more circumscribed."

The quantities of radium and thorium emanations contained in the air of certain soils, J. SATTERLY (*Proc. Cambridge Phil. Soc.*, 16 (1912), No. 6, pp. 514-533, figs. 5).—Measurements of radium and thorium emanations in the air of different soils to depths of 106 and 152 cm. showed at depths of from 100 to 150 cm. in gravelly soil about 2,000 times as much as there is usually in the atmospheric air.

The production and movement of nitric nitrogen in soils, R. STEWART and J. E. GREAVES (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 4-7, pp. 115-147, fig. 1).—This article embodies the results of investigations previously reported in Bulletins 106 and 114 of the Utah Station (E. S. R., 22, p. 617; 26, p. 616), as well as of later investigations by improved methods on a new series of plats on the same soil. These investigations dealt with the amount and distribution of nitric nitrogen in the soil to a depth of 10 ft. as affected more particularly by water conditions and crop.

The results obtained indicated a pronounced variation in nitric nitrogen content of the soil from foot to foot during the season due to movement by water, variation in nitrification, feeding of the plant, and fixation of nitric nitrogen in the form of insoluble protein by micro-organisms. The application of irrigation water had a distinct beneficial effect upon the formation of nitric nitrogen, being greatest where 15 in. of water was applied.

In cropped land there was always less nitrogen in the soil during the fall than in the spring. In fallow soil, on the other hand, more nitrogen was found in the fall than in the spring, but this surplus largely disappeared during the winter months.

The amount of nitric nitrogen in alfalfa and oat soils was low. In corn and potato soils it was high. Alfalfa was found to be a heavier feeder on soil nitrogen than potatoes notwithstanding the fact that the alfalfa was abundantly supplied with root tubercles. The concentration of the soil solution was very low in alfalfa and oat soils and high in fallow, potato, and corn soils. The concentration of the solution was always higher in fallow soil than in alfalfa, oat, and corn soil, and nearly always greater in unirrigated than in irrigated soil. It varied, however, quite widely not only with the crop grown and the amount of water applied but also at different depths in the soil. There was always a larger amount of nitric nitrogen in the fallow plats than in the cropped plats, but when the amount of nitrogen removed in the crop was taken into account it was found that more nitric nitrogen had always been formed in the cropped soil. The amount of nitric nitrogen was found to be more constant in the uncropped plats than in the cropped plats. The proportion of nitric nitrogen was found to be comparatively constant in the lower foot sections of the soil irrespective of the amount of water applied, up to 25 in., indicating that there was little leaching of the nitric nitrogen beyond the lower depths of sampling.

**Nitrates in soils**, F. L. STEVENS (*Science, n. ser.*, 35 (1912), No. 913, pp. 996-1000).—An abstract of this paper has already been noted (E. S. R., 26, p. 723).

**The influence of molasses on nitrification in cane soils**, S. S. PECK (*Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul.* 39, pp. 5-25, charts 8).—In continuation of previous experiments on this subject with solutions and small quantities of soil (E. S. R., 24, p. 224), observations were made on 24 lysimeters, previously described (E. S. R., 25, p. 824), filled with surface soil from the station field.

Four lysimeters received no nitrogen and 4 each received sodium nitrate, ammonium sulphate, and high-grade tankage in amounts furnishing 100 lbs. of nitrogen per acre. Eight received the same amount of nitrogen in form of a mixture of equal parts of the 3 fertilizing materials named. One series of lysimeters was irrigated with water alone, one with water containing the equivalent of the ash content of 40 gal. of molasses per acre-foot of 3,000,000 lbs.; one series received molasses at the rate of 40 gal. per acre-foot before each irrigation; and one series received molasses at the rate of 400 gal. per acre-foot 1 week before the first irrigation. The molasses used contained nitrogen 0.27 per cent, lime 0.84, magnesia 0.99, potash 5.68, phosphoric acid 0.18, sulphuric acid 1.58, and chlorine 3.66 per cent. For the purpose of these experiments the ash was assumed to be composed of potassium chlorid 7.69, potassium sulphate 1.53, magnesium sulphate 1.32, and calcium phosphate 0.40 per cent.

A study of the drainage water from the lysimeters gave results confirming the conclusions from the previous experiments, indicating that "molasses applied to land which is receiving the usual fertilizer applications as practiced in [Hawaii] will work harm by causing a part of the nitrogen applied as nitrate to revert back to less available or unavailable forms of nitrogen; by checking the nitrification of sulphate of ammonia dressings, and by retarding the ammonification and nitrification of the nitrogen of organic fertilizers. The harmful effect of molasses dressings is due entirely to the organic constituents of the molasses, the mineral matters having no influence. Dressing with carbonate of calcium does not correct such adverse action of molasses."

**Bacteriological studies of the fixation of nitrogen in certain Colorado soils**, W. G. SACKETT (*Centbl. Bakt. [etc.]*, 2. Abt., 34 (1912), No. 4-7, pp. 81-115, figs. 5).—This is substantially a reprint in the German language of Bulletin 179 of the Colorado Experiment Station (E. S. R., 25, p. 815).

**Regarding legume cultivation and inoculation experiments**, A. EICHINGER (*Pflanzer*, 8 (1912), No. 4, pp. 190-219).—Experiments were made to determine the value under Amani (German East Africa) conditions of inoculating soils (with nitro-bacterine) with and without fertilizers for the growth of *Desmodium tortuosum*, *Canavalia ensiformis*, soy beans, and cowpeas, and the value of these crops for green manuring purposes.

The best results were obtained by soaking the seeds before inoculating. The heavier classes of soil were not benefited by inoculation. Applications of superphosphate increased the number of nodules formed, whereas with sodium nitrate no nodules were formed.

The tests with different crops were for the most part inconclusive, and are being continued. The work with the soy bean, however, seemed to indicate that the production of this crop is not profitable for this region.

**Regarding a new method of soil aeration in its scientific and practical aspects** (*Deut. Landw. Presse*, 39 (1912), Nos. 41, pp. 483-485; 42, pp. 493-498).—This article is divided into three parts, as follows: (1) A description of the method and its development, by M. Friedersdorff; (2) observations on the effect on the soil of the above method of aeration, by P. Höldefleiss; and (3) a

theoretical discussion of the importance of soil aeration for bacteria and plant culture, by B. Heinze.

It is stated that, after several years' observations, the conclusion was reached that the most important factor concerned in the increased productivity of a soil from tile draining is the improvement in aeration. In order, therefore, to bring about more perfect aeration he conceived the idea of connecting the tiles with the atmosphere by means of flues or pipes, which constitutes the method here described. It is maintained that such a system, which entails very little additional expense beyond that of the original cost of tiling, brings about a complete circulation of the air not only in the tiles but also in the soil and, furthermore, that the temperature and humidity of the soil and of the atmosphere tend to equalize as a result, thus having a most important bearing on the productivity of the soil.

Determinations were made from time to time of the organic matter content and oxidizing power of soils aerated in this manner as compared with soils not aerated. The results, although indicating greater bacterial activity in the aerated soil, are as yet inconclusive. The experiments are being continued.

On the penetration of soluble fertilizers into the soil, A. DEMOLON and G. BROUET (*Ann. Sci. Agron.*, 3. ser., 6 (1911), II, No. 6, pp. 401-418, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 3 (1912), No. 4, pp. 897-899).—The investigations reported in this article have already been noted from a briefer report (E. S. R., 25, p. 120).

The chemical composition of farmyard manure as a measure of its value, C. CROWTHER and A. G. RUSTON (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 24 (1912), pp. 219-236).—This article is based upon a study of the manure obtained in 2 steer feeding experiments, the object of which was "to compare a ration including a heavy allowance of roots and a moderate allowance of concentrated foods with another ration including a moderate allowance of roots and a high allowance of concentrated foods. The foods used were precisely the same in each ration, the difference simply being in the relative proportions of roots and concentrated foods."

The composition of the different lots of manure produced and their effects upon crops as tested in field trials are reported. It was found that "the difference in composition between the manures produced by animals fed under the same conditions but on different rations may differ widely from that which the composition of the foods consumed would lead one to expect. This is especially the case where the amounts of 'roots' included in the rations differ greatly. The chemical composition of the manures by itself is not a reliable measure of their relative values. . . . The richer manure in each case apparently [gave] the better crop, but the differences in value thus far realized [were] well below those calculated from the chemical composition by the ordinary method of computation."

The effect of watery foods (roots) in increasing the bulk and reducing the fertilizing value of the manure was marked.

The manufacture of nitrates from the atmosphere, E. K. SCOTT (*Jour. Roy. Soc. Arts*, 60 (1912), No. 3104, pp. 645-667, figs. 12; *Nature [London]*, 89 (1912), Nos. 2227, pp. 463-465, figs. 3; 2228, pp. 490-492, figs. 4).—This is a very complete account of the present status and outlook of this industry, describing the various processes in use, the capacity of the works, the cost of power, and the possible extension of the industry.

The manufacture of nitrates from the atmosphere, H. E. P. COTTRELL (*Jour. Roy. Soc. Arts*, 60 (1912), No. 3108, pp. 756, 757).—This article contains statistics on the world's production and consumption of ammonium sulphate and

the consumption of sodium nitrate, 1906 to 1911, inclusive, supplementing data given in the article by E. K. Scott noted above.

**Potash salts a protection against frost,** MÅAS (*Illus. Landw. Ztg.*, 32 (1912), No. 6, pp. 39, 40, figs. 4).—Marked effects in preventing frost injury to rye and potatoes by liberal applications of potash salts are reported.

**Potash salts a protection against frost,** W. GOLTE (*Illus. Landw. Ztg.*, 32 (1912), No. 10, p. 77; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 902, 903).—Liberal applications of potash salts apparently prevented frost injury to rye by increasing the concentration of the soil water and thus preventing the freezing of the soil and by withdrawing a certain amount of water from the tissues of the plants.

**Fertilizer experiments with ground phonolite,** W. THAER (*Jour. Landw.*, 60 (1912), No. 1, pp. 19-30).—Comparative tests of 40 per cent potash salt and phonolite on beans and potatoes showed neither appreciable direct action nor after effect of the potash in the phonolite.

**Results of investigations of the potash deposits of Upper Alsace,** B. FÖRSTER (*Mitt. Geol. Landesanst. Elsass-Lothr.*, 7 (1911), No. 4, pp. 349-524, pls. 7; *abs. in Kali*, 6 (1912), No. 4, pp. 77-81; *Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 4, pp. 901, 902).—The character of these deposits as determined by numerous deep borings is described. It is estimated that they are capable of yielding 1,472,058,000 metric tons of 22 per cent potash salts.

**The composition of the Pacific kelps,** J. W. TURRENTINE (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 6, pp. 431-435).—In analyses of 81 samples of oven-dried seaweeds from the Pacific coast the potash (K<sub>2</sub>O) varied from 0.37 per cent (equal to KCl 0.59 per cent) in the stipe of *Pterygophora californica*, to 29.9 per cent (equal to 47.5 per cent KCl) in bulbs of *Pelagophycus porra*.

“When the average potassium chlorid content of the 29 samples of the northern kelps (from Puget Sound) is compared with that of the 27 samples of the southern (from the region of San Diego), the respective values being 21.3 per cent and 23.4 per cent, it appears that the content of the southern plants exceeds that of the northern.” However, choosing the 4 varieties in the northern collection which occur in the greatest quantities (the genera *Nereocystis*, *Macrocystis*, *Postelsia*, and *Egregia*—9 specimens), the average KCl content is 25.7 per cent, and the 2 genera of the north considered as a commercial source of potash, *Nereocystis* and *Macrocystis*, show an average content for 6 specimens of 29.4 per cent. The average content of the 2 specimens of *Macrocystis* from Puget Sound is 26.5 per cent; that of the 22 specimens from the south is 21.6 per cent.

“The average iodine content of the 30 specimens from Puget Sound is 0.155 per cent and of the 4 main varieties (10 specimens) is 0.14 per cent. The average of 6 specimens of the 2 giant kelps, the *Nereocystis* and the *Macrocystis*, is 0.16 per cent. The average percentage content of the southern kelps is 0.29, a value nearly twice that from the northern kelps.”

Of the 3 giant kelps *Nereocystis* contained on the average 32.6 per cent KCl, 0.14 per cent iodine; *Macrocystis* 22.2 per cent KCl, 0.27 per cent iodine; and *Pelagophycus* 31.3 per cent KCl, 0.36 per cent iodine.

In addition to the variations in composition between the varieties of kelps there was a marked variation between members of the same genus from different localities and from the same locality. There is also a variation strikingly shown in the case of *Pelagophycus* between the different parts of a single plant. These differences have been pointed out by Balch.

From analysis of a limited number of kelps it was found that phosphoric acid varied from 0.51 per cent in *Pelagophycus porra* to 1.84 per cent in *Macrocystis pyrifera*, and sulphur from 1.08 in *Nereocystis leutkeana* to 3.45 in *M. pyrifera*.

**Significance of the word kainit, A. ZARAGÜETA** (*Jour. Agr. Prat., n. ser., 23* (1912), No. 18, pp. 556, 557).—It is stated that the natural salt found in the Stassfurt deposits to which the name kainit was originally given has, according to Precht, the formula:  $MgCl_2 \cdot K_2SO_4 \cdot MgSO_4 \cdot 6H_2O$ . The theoretical composition of kainit is  $KCl \cdot MgSO_4 \cdot 3H_2O$ , according to Van't Hoff, who showed that Precht was at fault in maintaining that the potassium was present as sulphate. In fact, in all of the natural potash salts of the German mines of most commercial importance the potassium is present as chlorid. The term kainit is used at the mines to designate all products containing from 12.4 to 16 per cent of potash soluble in water, and less than 6 per cent of magnesium chlorid soluble in alcohol. The kainit group is therefore usually a mixture of various salts in which, however, the potassium is always combined with chlorine. Salts containing over 6 per cent of magnesium chlorid soluble in alcohol are classed as carnallite.

**Discovery of chalk and phosphatic sands in the Department of the Yonne, France, G. NEGRE** (*Compt. Rend. Acad. Sci. [Paris], 154* (1912), No. 20, pp. 1314-1316).—The geological character and estimated extent of deposits in the vicinity of Sens are briefly discussed.

**Report on departmental experiments with ground limestone, H. J. COLBOURN** (*Agr. Gaz. Tasmania, 20* (1912), No. 3, pp. 94-97, figs. 2).—The beneficial effect of ground limestone on mustard and rape in experiments here reported is ascribed to its favorable action on nitrification.

**Some bacteriological effects of liming, P. E. BROWN** (*Centbl. Bakt. [etc.], 2. Abt., 34* (1912), No. 4-7, pp. 148-172; *abs. in Jour. Chem. Soc. [London], 102* (1912), No. 597, II, p. 670).—This is substantially a reprint of matter contained in Iowa Station Research Bulletin 2 (E. S. R., 23, p. 428).

**Experiments on the action of sulphur as a fertilizer in 1911, BERNHARD** (*Deut. Landw. Presse, 39* (1912), No. 23, p. 275).—Experiments are reported which showed marked benefit from applications of sulphur (44 lbs. per plat of 600 sq. yds.) on hoed crops, especially potatoes and mangolds.

**The fertilizing action of sulphur, L. DEGRULLY** (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 33* (1912), No. 11, pp. 321-324).—This is mainly a review of investigations by Boullanger (E. S. R., 27, p. 27) and Demolon (E. S. R., 26, p. 819), with reference also to the suggestion of Gastine that the fertilizing effect of carbon bisulphid is due in part at least to the sulphur left in the soil in a fine state of division.

**Sulphur as a fertilizer (Abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 5, pp. 1109-1111).—This is a review of investigations by Boullanger, Demolon, Bernhard, and Degrully, referred to above.**

**Sand and ashes from Vesuvius, E. CASORIA** (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 9* (1910), Art. 6, pp. 26).—Analyses of a large number of samples show generally a rather high percentage of potash (about 7 per cent in some cases) and about 0.75 per cent of phosphoric acid.

**Artificial manures in Hungary, DE MIKLÓS DE MIKLOSVÁR** (*Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3* (1912), No. 4, pp. 899, 900).—It is stated that the use of fertilizers is increasing each year with the growing improvement in agriculture. The conditions under which the National Hungarian Agricultural Association will give prizes for the best articles on the importance of the use of superphosphates in Hungary are stated.

The consumption of chemical and mineral fertilizers in Spain, T. CALLEGO (*Mem. Dir. Gen. Agr., Minas y Montes [Spain], 1912, pp. 361-365, pl. 1; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 5, pp. 1113, 1114*).—Statistics collected by the ministry of agriculture show a marked increase in the use of fertilizers due to an energetic propaganda, low prices, improved laws relating to inspection and purchase, and formation of purchasing associations. It is estimated that the total consumption in Spain in 1911 was 581,320 metric tons, of which 82,580 tons was consumed in Valencia alone. A large proportion of the fertilizers is now imported.

Inspection and analyses of commercial fertilizers in Mississippi, 1911-12, W. F. HAND ET AL. (*Mississippi Sta. Circ. 34, pp. 31*).—This circular contains the analyses and valuations of 88 samples of fertilizer drawn by regular inspectors and also guaranties for all brands registered to date.

Analyses of fertilizers, spring season, 1912, B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr., 33 (1912), No. 4, pp. 95*).—This bulletin contains analyses of fertilizers collected by the fertilizer inspectors of the state department of agriculture during the spring of 1912, as well as a list of brands of fertilizers registered for sale during the season 1911-12.

The inspection of cotton-seed meal, season 1911-12, W. F. HAND ET AL. (*Mississippi Sta. Bul. 156, pp. 3-33*).—This bulletin contains tables of analyses of samples of cotton-seed meal drawn by inspectors from shipments in various parts of the State and of so-called official samples forwarded by oil mills in accordance with the requirements of the law. The valuation of cotton-seed meal is briefly discussed.

The mixing of fertilizers, G. VECCHI (*Riv. Agr. [Parma], 18 (1912), No. 23, pp. 355-357*).—This is a brief discussion containing a convenient table showing compatibles and incompatibles in fertilizing materials.

Home mixing and general fertilizer formulas (*South Carolina Sta. Circ. 4, pp. 7*).—Forty formulas for the use of farmers in preparing home mixtures of fertilizers are given.

## AGRICULTURAL BOTANY.

Practical botany, J. Y. BERGEN and O. W. CALDWELL (*Boston, New York, Chicago, and London, 1911, pp. VII+547, figs. 388*).—This book is designed to supply the needs of students in secondary schools, the recommendations regarding the botanical courses suggested by the Botanical Society of America and the North Central Association of Colleges and Secondary Schools being followed. After treating of plant life and structures, the great groups of plants are discussed at some length. The authors include the principles of plant nutrition, and the relation of plant nutrition to soils and climate and to the food of animals and men. Discussions are also given of diseases produced by parasitic plants, the propagation of plants, plant breeding, forestry, and the main uses of plants and plant products.

The relative amount of information of economic importance that is included in this work makes it appear to be well adapted to secondary schools, particularly those leading to higher institutions where the economic relations of plants are featured.

A laboratory manual of general agricultural bacteriology, E. G. HASTINGS, C. HOFFMANN, and W. H. WRIGHT (*Madison: Univ. Wis., 1911, pp. 47*).—This manual gives an outline of a course of laboratory instruction which is designed to convey to the student some of the principal relations of bacteria to farm operations and to illustrate their importance in the daily life of the farm. The

four principal divisions treated are soil bacteriology, dairy bacteriology, the bacteriology of the diseases of animals, and the bacteriology of foods.

**A biologic and taxonomic study of the genus *Gymnosporangium*, F. D. KERN** (*Bul. N. Y. Bot. Gard.*, 7 (1911), No. 26, pp. 391-394, pls. 11, figs. 36).—The results of a study begun at the Indiana Station in 1906 on the biology and taxonomy of the genus *Gymnosporangium* are given. Preliminary notes on some of the phases of the investigation have appeared previously (*E. S. R.*, 19, p. 754; 20, p. 453; 23, p. 354).

The author recognizes 40 species of the fungus, all of which are described at length. Under the biological studies accounts are given of experimental investigations on the life histories of different species of the fungus. Cultures were made of 26 species and in 18 they were successful. Of this number 9 were cultivated for the first time and their alternate hosts demonstrated, the others confirming previous reports.

The economic importance of the species is discussed, especially those whose recidial forms occur on such trees as the apple, pear, and quince. The methods of control that have been suggested are reviewed, and the author points out some of the difficulties attending spraying by reason of the prolonged season of the maturing of the teleutospores. The planting of resistant varieties of apples, pears, etc., is thought to offer promising results.

**Natural history, morphology, and cytology of *Azotobacter chroococcum*, A. PRAZMOWSKI** (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 11-14, pp. 292-305).—This is a somewhat detailed biological study of this dimorphic schizomycete.

It is stated that morphologically it presents itself in its first or vegetative stage as a bacterium, in the fruiting stage as a micrococcus. Under certain circumstances it resembles a ciliated free-moving fission fungus. The division of the nucleus marks the first step in cell division. In the resting stage the nucleus assumes a globular form, having a strongly refractive nucleolus, with clearly differentiated bounding layer. The individuality of the nucleus appears to be practically lost at times owing to its relations to the cytoplasm. The so-called sarcina forms are said to be morphologically and physiologically similar to the endogenous spores of other bacteria, in particular *Bacillus bütschlii*.

**The physiology of denitrifying bacteria, H. VON CARON** (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 1-6, pp. 62-116).—This is an account of the author's studies in extension of the work of Koch and Pettit (*E. S. R.*, 23, p. 123), employing cultures in soil of 3 common denitrifying bacteria, viz, *Bacterium hartlebi*, *Bacillus pyocyaneus*, and *Bacterium fluorescens liquefaciens*. The investigations relate to the requirement and utilization of food and energy materials by these bacteria in denitrification and the influence of atmospheric oxygen in that process. The principal conclusions announced are as follows:

Dextrose is a most suitable source of energy for nitrate reduction. So is fresh straw; but in rotting this loses much of its available carbon, so that compost seldom shows much loss of nitrates by bacterial activity. Cellulose may also serve as a source of energy in mixed cultures but in less degree. Other sources of energy of varying availability are mentioned. The addition of nitrogen increases the rate of denitrification, and this rises toward a maximum of intensity per unit of energy used.

Investigations in the presence of hydrogen tend to confirm the view that denitrifying bacteria are responsible for the loss of nitrates observed to occur in the presence of a source of energy and of nitrates with exclusion of air. The hydrogen is said to play here the rôle of a too high water content in the soil; whence it is inferred that any means of excluding air in soils may lead to

nitrate destruction by these bacteria when present and other conditions are favorable.

The most divergent denitrifying organisms appear to act in the same ways on exclusion of oxygen. Simultaneously with the admission of air an increase of proteins occurs with coincident increase of energy requirement. The most diverse experiments indicate that the degree of air access did not affect the relation between synthesis and use of energy material.

The 3 bacteria studied do not show the same activity and nitrate requirement per unit of energy material used. The optimal relation between the carbon and the nitrate used is for the 2 stronger bacteria (*B. pyocyaneus* and *B. fluorescens liquefaciens*) 1 per cent dextrose to 1.6 per cent potassium nitrate. Reduction of nitrate supply far below that of carbon greatly reduces the intensity of the process. All of these 3 kinds of bacteria use carbon the more freely as more individuals are present. With a sugar concentration of more than 1 or 2 per cent, a depression of denitrification occurs, as thereby (through the building of fatty acids) the development of the denitrifying bacteria is retarded. The increase of alkaline carbonates has the opposite effect. Increased concentration of dextrose within limits is accompanied by its increased employment as a source of energy.

These experiments confirm the findings of Koch and Pettit and of Marr (E. S. R., 23, p. 430) that in the soil, under otherwise favorable conditions of moisture, etc., a loss of nitrates may still occur. No certain explanation is at hand, but the suggestion is made that an increased production of carbon dioxide and the indirectly produced exclusion of air may in part account for the destruction of nitrates observed.

It is suggested also that an explanation may now be expected of the very different results obtained by investigators, and that a point of departure for investigations of great importance has been reached.

**Metabolism and translocation in young foliage trees, H. BAUER** (*Naturw. Ztschr. Forst u. Landw.*, 9 (1911), No. 9, pp. 409-419).—This is a further account of the author's investigations of the nutritive changes in young trees (E. S. R., 25, p. 27). This report gives detailed and tabulated particulars of changes (expressed in percentages) observed in the study of the second year's growth of ash trees during the four successive periods of about 50, 50, 70, and 60 days, extending from February 27 to November 17.

**The periodicity of nutritive processes in young beeches, W. KÜBLER** (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 4-5, pp. 161-187, figs. 2).—This is contributory to the work of E. Ramann (E. S. R., 26, p. 443; 27, p. 229) and of H. Bauer (see above). The author investigated the seasonal changes occurring in beeches of 2 years' growth as regards nutritive requirements, the formation of dry substance, etc., in the plants. The results are given in tabular form of analyses made of the whole plant, of stem and root, together and separately, and of the leaves.

The results as regards the whole plant, which are graphically represented, show that phosphoric acid, nitrogen, potash, lime, and magnesia (which follow much the same general course but show individual differences) all decrease until early in May. The percentages then rise sharply until about the middle of September when a decline almost as steep sets in, reaching by November approximately the same levels as about the middle of July. The curves are very much steeper in case of those plants grown under the more favorable conditions.

**The periodicity of synthetic processes in young foliage trees, H. BAUER** (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 4-5, pp. 188-199).—This is a report in continuation of the work carried on by this author, E. Ramann, and

W. Kübier (see above). Beginning on March 15 with oaks about 1 year old, analyses were made of the growing plants after four successive periods of 70, 32, 36, and 50 days, closing September 19. The results of these numerous analyses as regards potash, soda, lime, magnesia, oxid of iron, silicic acid, and nitrogen found in the whole plant, the stem and root, and the foliage, respectively, are given in tabular form.

The relations between changes in protein structure and respiration.—I, The influence of atmospheric oxygen on proteolytic ferments in plants, W. PALLADIN and G. KRAULE (*Biochem. Ztschr.*, 39 (1912), No. 3-4, pp. 290-301).—From studies of *Agaricus campestris* and etiolated leaves of *Vicia faba*, both in ordinary air and in an oxygen-free atmosphere, the authors conclude that autolysis of proteins in killed plants is increased by the presence of oxygen in the amount found in ordinary air, especially where the plants are of loose structure. The dependence of autolysis upon oxygen is probably indirect. It is claimed that the various ferments present may work independently or even antagonistically in the cells of the dead plants, but that the conditions most favorable to the work of such ferments have not yet been ascertained.

The significance of respiration pigments in the oxidation processes of plants, W. PALLADIN (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 3, pp. 104-107).—In continuation of previous work (E. S. R., 25, p. 124; 26, p. 326), the author presents a preliminary report on his later investigations on this subject, the principal conclusions being as follows:

(1) The rôle played by respiration pigments in the oxidation processes consists in the withdrawal of hydrogen from the substance to be used as an oxidizer. (2) The oxidases are water-forming ferments. (3) During respiration all the hydrogen of the glucose is oxidized exclusively through the oxygen of the air. (4) The water formed during respiration is exclusively of aerobic origin. (5) The oxidation of glucose, with the aid of respiratory pigments, takes place with participation of water. (6) The oxidation of glucose during respiration goes on with the employment partly of the oxygen from the water assimilated in the process of respiration, partly of that from the glucose. (7) During respiration, water is not only separated but is also assimilated. A brief discussion is given of some of the changes involved in these processes.

The influence of diastase and of emulsin on alcoholic fermentation and the respiration of plants, S. L'YOV (*Ztschr. Gärungsphysiol.*, 1 (1912), No. 1, pp. 19-34, fig. 1).—Substantially the same as an article already noted (E. S. R., 27, p. 221).

The relation of protoplasmic-streaming movements to movements of starch grains within the cells, A. L. HEILBRONN (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 3, pp. 142-146).—A preliminary report on investigations still in progress.

In the course of his studies, first with *Phaseolus multiflorus* and *Vicia faba* and later with *Calceolaria chelidonioides*, *Verbascum thapsus*, and *Mimulus moschatus*, the author found that if cells are placed in their natural position with the starch grains lying on the lower cell wall and the cells are then rotated through 180° the grains after 10 or 15 minutes begin to descend, partly in consequence of protoplasmic movement but partly by gravity, some passing through the vacuole, each grain or group in such case pulling through after it a thread of protoplasm. After reaching the bottom, which required from 10 to 28 minutes, the grains were observed to be carried upward and around by the protoplasmic movement which, once started, persisted for from 40 to 70 minutes.

The author expresses the opinion that either the weight of the starch is the stimulus to further motion of the plasma to which the cell reacts in this way, or

else that the effects of the friction of the starch grains or the impetus of their descent are communicated to the medium. It is suggested that a way is thus opened for further study of the properties of the several cell contents.

The carbohydrates of the snowdrop leaf and their bearing on the first sugar of photosynthesis, J. PARKIN (*Bio-Chem. Jour.*, 6 (1911), No. 1, pp. 1-17, fig. 1).—This is a fuller account of work already in part reported (E. S. R., 21, p. 319).

The results as first given have been confirmed. Only 3 carbohydrates were present in these leaves in appreciable quantity, viz. sucrose, glucose, and fructose. The total quantity of these in a leaf was from 20 to 30 per cent of the dry substance, or from 4 to 6 per cent of the fresh, active leaf. The greater proportion in the lower part of the leaf may be due to the greater shading of this part as the amount was greater in leaves from thick clumps. The lower part of the leaf seems to function somewhat as storage tissue for sugars when obscured. It seems that, as spring advances, the hexoses increase at the expense of the sucrose. The leaves, when detached and insolated, contain decidedly more sucrose than their controls, while the quantity of hexoses remains much the same. The fructose as a rule is in excess of the glucose. Leaves when darkened lose sucrose rapidly during the first 48 hours, after which the proportion remains fairly constant.

In general, the results favor the conclusion announced by Brown and Morris that sucrose is the first sugar to arise on photosynthesis, and that the two hexoses, glucose and fructose, as well as starch, are derived from sucrose. Important services by sucrose in relation to circulation, storage, and transformation purposes are suggested.

The origin and function of pentosans in plants, C. RAVENNA, O. CERESER, and O. MONTANARI (*Gaz. Chim. Ital.*, 41 (1911), II, No. 2, pp. 115-129).—Substantially the same work as previously reported (E. S. R., 24, p. 228), with the conclusions that the pentosans probably have their origin in sugars and that among other functions they perform that of storage of reserve materials.

The significance of mucilage in the germination of seeds, C. RAVENNA and M. ZAMORANI (*Gaz. Chim. Ital.*, 41 (1911), II, No. 2, pp. 138-143).—This is substantially the same as a report previously noted (E. S. R., 24, p. 534).

Dimorphism of chlorophyll grains in some plants, U. GIOVANNONZI (*Nuovo Gior. Bot. Ital.*, n. ser., 19 (1912), No. 1, pp. 39-51, figs. 2).—Studies carried on with numerous plants, more particularly *Portulaca oleracea* and *Alternanthera sessilis amana*, led the investigator to the conclusion that the dimorphism of chloroplasts, observed in numerous and widely separated groups, is related to the environment of the plant and the principal function of the cells under observation. In leaf parenchyma of mainly assimilative function the chloroplasts were found to be larger and more active, while in regions more concerned with conduction these grains were reduced in size and seemed to be less active. Heat, dryness, and light also appear to show some relation to the differences observed.

Remarks on a new method of studying stomatal aperture of stomata, EMMY STEIN (*Ber. Deut. Bot. Gesell.*, 30 (1912), No. 2, pp. 66-68).—Concerning the method described by Molisch (E. S. R., 27, p. 221) which is stated to have been previously discovered and used by others, the author makes the following claims:

The number of substances suitable for the purposes of infiltration is much larger and the range of possibilities of the method is much greater than claimed by Molisch. For example, melted paraffin, entering only wide apertures, and petroleum ether, which penetrates exceedingly minute ones, are much further apart than are alcohol and benzol. It is claimed that estimates of apertures

may be made with a high degree of accuracy beyond the point where Molisch regarded the stomata as practically closed. Also, these more sensitive indicators are less injurious to the cells than are benzol and xylol.

**Heterozygosis in evolution and in plant breeding.** E. M. EAST and H. K. HAYES (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 243, pp. 58, pls. 8*).—In cooperative work between this Department, the Connecticut State Station, and the Bussey Institution, the authors have studied heterozygosis in evolution and in plant breeding, predicating their belief that Mendel's law—that is, the segregation of character factors in the germ cells of hybrids and their chance recombination in sexual fusions—is a general law; that stimulus to development is greater when certain, or possibly all, characters are in the heterozygous condition than when they are in a homozygous condition; and that this stimulus to development is cumulative up to a limiting point and varies directly with the number of heterozygous factors in the organism.

Their studies were made with 30 varieties of maize and several species of *Nicotiana*. As a result of their investigations the authors believe they have demonstrated that "the decrease in vigor due to inbreeding naturally cross-fertilized species and the increase in vigor due to crossing naturally self-fertilized species are manifestations of one phenomenon, heterozygosis. Crossing produces heterozygosis in all characters by which the parent plants differ. Inbreeding tends to produce homozygosis automatically. The phenomenon exists and is in fact widespread in the vegetable kingdom. Inbreeding is not injurious in itself, but weak types kept in existence in a cross-fertilized species through heterozygosis may be isolated by its means. Weak types appear in self-fertilized species, but are eliminated because they must stand or fall by their own merits."

The experimental data upon which these conclusions are based have been obtained entirely from plants, but observations on animal hybrids and published records lead the authors to believe that the facts are the same among animals, and that their conclusions will apply equally to the animal and the vegetable kingdoms where organisms are reproduced sexually.

A bibliography is appended.

**The inheritance of red color, and the regularity of self-fertilization in the common jute plant.** R. S. FINLOW and I. H. BURKILL (*Mem. Dept. Agr. India, Bot. Ser., 4 (1912), No. 4, pp. 73-92*).—From 1902 to 1907 the authors made a survey of the different races of jute cultivated in India, and as a result of their survey they recognize 33 races, including 3 which are grown as vegetables. These are grouped according to color types, and the inheritance of color in them is shown.

It is stated that when a pure green jute is crossed with a fixed red plant the Mendelian law is obeyed, the red acting as a simple dominant. The  $F_1$  generation of hybrids appears to consist of plants of one tint of redness. The  $F_2$  generation, on the other hand, varies widely in the amount of red color the plants contain.

The authors in their studies found that self-fertilization is the rule with this plant, probably not more than 2 per cent of the plants under the most favorable conditions being the result of cross breeding.

**Department of botanical research.** D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 10 (1911), pp. 49-68, pl. 1*).—An outline is given of the investigations carried on by the staff attached to the botanical research laboratory at Tucson, Ariz., a number of the investigations having been previously reported upon at length (*E. S. R.*, 25, pp. 219, 327, 732; 26, pp. 433, 532, 628; 27, pp. 29, 329, 331).

## FIELD CROPS.

Water requirements of crops in India, II, J. W. LEATHER (*Mem. Dept. Agr. India, Chem. Ser., 1 (1911), No. 10, pp. 205-281, pl. 1, figs. 34*).—Earlier work by this author on the same subject has already been noted (E. S. R., 23, p. 331).

Tables and charts present data on the amount of water transpired by corn, wheat, flax, barley, oats, gram (*Cicer arietinum*), peas, sugar cane, and rutabagas on various soils, in pots of different sizes, and when treated with various fertilizers. From these and other data presented the author draws certain conclusions.

The ratios between the amounts of water transpired and the crop weights produced were apparently not affected by the nature of the soil so long as the water supply did not fall below a certain concentration. The concentration of water in the soil required for good development varied with the soil. In the Pusa soil, 10 per cent was sufficient for good plants, but in a soil designated by the author as black cotton soil, 25 per cent sufficed only for the most meager growth. The reduction in concentration in the Pusa soil was more or less uniform for about 5 or 6 ft., below which the change was smaller. After allowing for the moisture which evaporated directly from the soil into the air, a comparison of the observed decrease of water in a unit column of soil with the crop weight produced gave approximately the same ratio as that obtained by the pot culture method. Thus most of the water required was accounted for by the observed decrease of water within the root range, while the data obtained in these experiments may be accounted for by supposing that the quantity of water which moves through the soil in a time unit is dependent on concentration, distance, and physical character of the soil. The author believes that temperature also has an important influence and that a laboratory method for the estimate of the soil's water-conducting capacity would be desirable.

[Dry farming soil preparation methods], A. E. V. RICHARDSON (*Dept. Agr. So. Aust., Rpt. Dry Farming Conf., 1 (1911), pp. 14, 15*).—The results given are for the third year of a test already noted (E. S. R., 26, p. 631).

During this third season only slight differences could be attributed to variations in time or frequency of subpacking. The 3 plats plowed 6 in. deep gave slightly lower yields than those plowed only 4 in. deep. From the test as a whole, however, the author concludes that subpacking gives a substantial profit under the conditions obtaining at Hammond in South Australia.

[Field crops at the Delta substation, 1911], G. B. WALKER (*Mississippi Sta. Bul. 157, pp. 3-10, 13-23, figs. 4*).—In a variety test of wheat the estimated yields ranged from 16 to 35 bu. per acre, the leading varieties apparently being Blue Stem and Klondike.

In a fertilizer test with cotton of cotton-seed meal, acid phosphate, and kainit applied singly and in various mixtures, the highest yields and the greatest net increases in value, after deducting the cost of fertilizers, followed applications of (1) 200 lbs. cotton-seed meal and 50 lbs. kainit, (2) 200 lbs. cotton-seed meal, 150 lbs. acid phosphate, and 50 lbs. kainit, and (3) 150 lbs. acid phosphate, and 50 lbs. kainit. In a test of applications of lime alone and in a mixture with other materials the yield of 1,366 lbs. of seed cotton per acre followed an application of 1,000 lbs. of lime as compared with 1,516 lbs. on the check plat, and 1,666 lbs. after an application of 200 lbs. cotton-seed meal, 150 lbs. acid phosphate, 50 lbs. kainit, and 1,000 lbs. lime. In another test the total seed cotton yield on the check plat was 1,549 lbs. as compared with 1,649 lbs. after what the author terms a normal application of 200 lbs. cotton-seed meal, 150 lbs. acid phosphate, and 50 lbs. kainit. A yield of 1,733 lbs. followed an application of double this normal mixture.

In another comparison "of varying amounts of cotton-seed meal, acid phosphate, and kainit, other elements being normal, with no fertilizer," the highest yield followed an application of 600 lbs. cotton-seed meal, 150 lbs. acid phosphate, and 50 lbs. kainit, but the highest net profit followed the use of 200 lbs. cotton-seed meal, 150 lbs. acid phosphate, and 50 lbs. kainit. On another plat, however, this latter mixture was applied at an apparent financial loss. In a test of different nitrogen sources and of applications made entirely at planting time, or half at planting and half on July 20, 2,483 lbs. of seed cotton per acre was obtained after fertilization with 80 lbs. of nitrate of soda on each of these two dates as compared with 2,133 lbs. when 160 lbs. were applied at planting time. An application of 400 lbs. of cotton-seed meal was followed by a lower yield than that secured on the check plat. An application of 200 lbs. of cotton-seed meal at planting time and 80 lbs. of nitrate of soda, July 20, was followed by a yield of 2,216 lbs. of seed cotton per acre. This application ranked second in value of increased yield over the cost of the fertilizer used, the divided application of nitrate of soda being first in this respect as well as in yield. Spacing and variety tests are noted on page 434.

Better yields of peanuts were obtained from plants planted during the first week in June than on other dates, and from plantings 16 in. apart in rows 3 ft. apart than at other distances. No increase in yield followed the use of fertilizers for peanuts on a fertile sandy loam.

Brief progress reports are also given on tests with corn, alfalfa, oats, and soy beans, and with wheat and vetch followed by soy beans.

[Cabbage and potatoes at the New Mexico Station], F. GARCIA (*New Mexico Sta. Rpt. 1911, pp. 33-37, fig. 1*).—Four different plantings of cabbage were made at intervals of about 2 weeks, beginning March 2. The earliest planting gave the best results on the whole, but the second planting did almost as well, while the last planting, made April 17, was too late to do much good.

Practically no yields of potatoes were secured in either plat or pot tests. The plants in pots in a more humid section of the greenhouse grew considerably taller than those in the drier portion or those in the field, but the size of the vines did not seem to affect materially the size or yield of tubers.

Results of cooperative experimental work for 1911, F. G. TARBOX, JR. (*South Carolina Sta. Circ. 5, pp. 3-19*).—The results of cooperative experiments the station is conducting with farmers in the State are briefly noted. In the spring of 1911, the station distributed among the farmers of the State for this work about 140 bu. of cotton seed, about 60 bu. of corn of the Marlboro Prolific, Boone County White, and Coker Williamson varieties, and a quantity of seed of winter cover crops, including vetch, clover, and rye.

Tables of field crops, J. N. HARPER (*South Carolina Sta. Circ. 2, pp. 18*).—Popular information regarding the culture of field crops adapted to the South is presented in tabular form.

Competition in cereals, E. G. MONTGOMERY (*Nebraska Sta. Bul. 127, pp. 3-22, figs. 7*).—This bulletin states the results of tests in which wheat and oats were planted  $\frac{1}{4}$ ,  $\frac{1}{2}$ , 1,  $1\frac{1}{2}$ , and 2 in. apart in rows to determine the percentage of plants which survive competition of these different degrees of intensity. The competition of well developed with poorly developed kernels and of one variety with another was also tested. Data are presented in 19 tables from which the author concludes that the percentage of plants which survive until harvest decreases as the rate of planting is increased. In these tests the total decrease amounted to 34 per cent and the relative survival of the thinnest and thickest stands averaged 75 and 56 per cent, respectively.

When plump and small or poorly developed seed were alternated in the same row, the decrease in number of plants was 28 and 38 per cent, respectively, but

when the same grades were planted alone the decreases were 35 and 40 per cent. Plants from all grades decreased markedly from various causes besides competition. Since natural elimination of weaklings from either large or small seed has been going on for ages, it would seem that artificial seed separation by fanning mill or screens could not increase the efficiency of seed, particularly since the usual method of thick seeding permits the natural elimination of one-half the plants without affecting the yields.

The desirability of separating pure strains is indicated by the fact that the variety which when sown alone is the best yielder, in a mixed sowing may be dominated by a less productive type. When the seeds of 2 varieties were alternated in the same row, the yield of the mixture was always greater than that of either variety alone. Seed from corn strains which had been grown for 6 years at the rates of 1, 3, and 5 plants per hill averaged 34.9, 38.5, and 41 bu. per acre, respectively, in 1911.

The manuring of grass land (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 13, 1910; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 941*).—A brief progress report on fertilizer and other tests conducted at 9 points in Oxfordshire in 1909-10. Phosphorus applications gave profitable returns in most localities and the addition of potash and nitrogen still further increased the yields.

The manuring of grass land (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 13, 1910; abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 941*).—This is a report of tests similar to those noted above, but conducted at 18 points in Bucks.

The grasses and grass-like plants of New Mexico, E. O. WOOTON and P. C. STANDLEY (*New Mexico Sta. Bul. 81, pp. 176, pls. 12, figs. 32*).—This bulletin is intended to supply information with regard to the individual grasses and grass-like plants of New Mexico to dry farmers, stockmen, and students. It contains a tentative relief map and an outline map showing the distribution of the principal grass societies, a technical description of each species, and a key for their determination.

Studies in Indian fiber plants, A. and G. L. C. HOWARD (*Mém. Dept. Agr. India, Bot. Ser., 4 (1911), No. 2, pp. 9-36, pls. 7*).—Notes are given on the botanical and other characters of varieties and types of *Hibiscus cannabinus* and *H. sabdariffa*.

Peruvian alfalfa, A. OPAZO (*An. Agron. [Santiago de Chile], 6 (1911), No. 3-4, pp. 365-375*).—A brief account is given of tests of Peruvian and Chilean alfalfa sown separately and mixed in various proportions. Physical and chemical analyses of the soil of the Coquimbo experiment fields are also reported.

Lucern (*Jour. New Zeal. Dept. Agr., 4 (1912), No. 3, pp. 188-190, figs. 2*).—Notes on the vegetation habits of a number of alfalfa varieties tested are given.

Tests of treated and untreated beet seed, H. K. GÜNTHER (*Centbl. Zuckerindus., 19 (1911), No. 30, p. 1021; abs. in Centbl. Bakt. [etc.], 2. Abt., 32 (1912), No. 6-12, p. 308*).—Additional tests of prepared seed (*E. S. R., 25, p. 135*) showed a greater percentage of germination, a higher degree of resistance to injurious influences, and a tendency to earlier sprouting. It is stated also that the favorable yield reported from the earlier observations was maintained.

Germination tests of the different colored seeds of red clover, B. KAJANUS (*Landw. Jahrb., 41 (1911), No. 3-4, pp. 527-533*).—Tables state in full the data obtained in germination and other tests of red clover seed of different colors. The relation of color to rate of germination is also discussed, and a bibliography of 4 titles is given.

Yellow and brown seeds appeared about equal in weight, but violet seeds were much heavier. Violet seeds germinated somewhat better than yellow ones and both excelled brown seeds in this respect. The percentage of hard seed was

exceedingly variable, and although it averaged lowest among the violet and highest among the brown seeds it had no apparent connection with color.

Native seed corn, E. G. MONTGOMERY (*Nebraska Sta. Bul. 126, pp. 3-13, figs. 4*).—At the Nebraska Station native seed of 6 leading corn varieties was compared for 2 and 3 years with that grown in either Iowa or Illinois. In every case the native seed gave the better yield, the average difference being 6.2 bu. These tests were conducted during the period 1903-1905. In 1909 seed representing 3 different degrees of acclimatization was tested. Show corn of 5 varieties grown in Illinois, Indiana, and Ohio produced average yields of 39.8 bu. per acre as compared with 45.6 bu. per acre in case of 5 varieties of Nebraska-grown seed and 48.8 bu. per acre in case of 7 local varieties grown near the station.

In central and western Nebraska a number of farmers conducted cooperative tests in 1908-9. In 1908 varieties native to the localities of those reporting averaged 30.5 bu. per acre as compared with 24.1 bu. per acre from seed furnished by the station from western or central Nebraska. In 1909 the varieties could be divided into 3 groups: Those from eastern Nebraska, which gave an average yield of 20.9 bu. per acre, those from central and western Nebraska which averaged 21.9, and those from the growers' own or native seed which averaged 25.4 bu. per acre.

It is concluded that it will be safer for growers in western Nebraska to use their native seed than to try importing seed, even from the eastern part of the State.

Studies in water requirements of corn, E. G. MONTGOMERY and T. A. KIESSELBACH (*Nebraska Sta. Bul. 128, pp. 3-15, figs. 4*).—The authors summarize the results of earlier work at this station on the water requirements of corn, already noted (*E. S. R., 24, p. 137; 25, p. 832*).

As it has been noted in the past that water loss was more closely related to humidity than to any other factor, the humidity of one greenhouse was maintained at that of the surrounding atmosphere by leaving it open, while that of another was kept much higher by means of atomizers and wet floors. Eight corn plants were grown in each house. Some of the data collected for those grown in the dry and humid greenhouses, respectively, were mean relative humidity at night, 48 and 72 per cent; by day, 37 and 58 per cent; mean temperature at night, 80 and 75° F.; by day 91 and 88°; total weight of 8 plants, 670.36 and 861.77 gm.; average leaf area per plant, 1,079 and 1,070 sq. in.; total water used, 227.785 and 184.230 kg.; water to produce 1 gm. of dry matter, 340 and 191 gm.; water per square inch of leaf area, 27.3 and 19.2 gm.; and water evaporated from 36 sq. in. of free surface, 3,891 and 2,187 gm. These figures are for 1911. In 1910 and 1911, 250 and 345 gm. of water, respectively, were required per gram of dry matter produced.

In work on the relation of water requirements to soil fertility, 3 lots of 4 cans each were filled respectively with an infertile, residual sandstone soil, a quite fertile black alluvial pasture soil, and a mixture of the two. Another series of cans also received 2.4 lbs. per can of moisture-free sheep manure, equivalent to an application of 12 tons per acre. Analyses of the soils used are given. The water requirements of the infertile, intermediate, and quite fertile soils were found to be 549.5, 478.9 and 391.8 gm., respectively, per gram of dry matter produced as compared with 350.3, 341.3, and 346.6 gm. in case of the manured soils. For the fertile soil the decrease was small, and it is considered doubtful whether, under field conditions, adding manure to soils of good fertility would decrease the water requirements.

The "Williamson Plan" of corn culture (*South Carolina Sta. Circ. 3, pp. 8*).—A description of the Williamson method reprinted from Bulletin 124 (E. S. R., 18, p. 731).

Cotton in Hawaii, C. K. McCLELLAND and C. A. SAHR (*Hawaii Sta. Press Bul. 34, pp. 24, figs. 2*).—This is a report on the cotton industry of the Hawaiian Islands, which contains directions for the production of the crop and a statement of the results of experiments on Sea Island and Caravonica cottons in continuation of earlier work (E. S. R., 27, p. 135).

As regards Caravonica cotton, "the yield per acre upon the station grounds from 1-year-old trees which had been pruned in December, 1910, was at a rate of 531 lbs. of lint per acre. Upon similar trees pruned in March, 1911, the yield was only at the rate of 363 lbs. per acre, the average yield upon the field being 448 lbs. per acre, which is approximately four times the yield that was obtained from the same field in 1910."

Pinching back undertaken to induce the growth of fruiting branches and increase the yield restricted vegetative growth but showed no great effect on the yield.

A brief note is given on a trial of semiannual pruning and the production of 2 crops per year by E. C. Smith, a pioneer cotton grower of Pearl City, Oahu. The method consists in picking a crop in June and July, immediately pruning back the plants and giving enough irrigation to start new growth, which makes a crop in December and January. At this time another pruning is given which results in another crop in June and July. "Upon 3-year-old plants pruned in July of 1910 a winter crop of 2.5 lbs. per tree was obtained, while in the following July 4.7 lbs. were picked, making a total of over 7 lbs. seed cotton per tree for the year." This includes all the cotton which opened on the pruned branches within 2 weeks after pruning. When the entire neighborhood follows this method the cotton bollworm can be controlled at nominal expense.

Sea Island cotton seemed to thrive better as an annual than as a perennial, and an acre produced 292 lbs. of lint.

Recent cotton experiments (*Mississippi Sta. Bul. 155, pp. 29*).—This is a continuation of earlier cotton experiments in Mississippi (E. S. R., 23, p. 39), and consists of 4 papers.

I. *Results from the Central Experiment Station, J. W. Fox et al. (pp. 4-14)*.—Meteorological data are followed by a statement of the results of a variety test in which Sunflower, Rowden 116, Columbia, and Cook stood highest in total value of lint and seed per acre in 1911. In 1910, 5 strains of Cook and the Triumph and Covington-Toole varieties constituted the first 7 in money value.

Applications of 288 lbs. each of kainit and acid phosphate were followed by approximately equal 5-year average yields, both greater than those secured when either was applied with cotton-seed meal or when both were used together. Still higher yields, however, followed the application of 8 tons of manure or of 4 tons of manure with phosphate, kainit, or lime. Another table states the relative earliness of the crop secured after the various applications in different fertilizer tests in 1911.

"The application of from 200 to 400 lbs. of potash to land on which cotton rusts badly is usually profitable." "We do not get profitable results from potash used here on soils where cotton does not rust."

Cotton topped July 15 and August 1 yielded 1,931 and 1,788 lbs. of seed cotton per acre, respectively, as compared with 1,756 lbs. secured from the untopped cotton. The order of yields was exactly reversed in 1910, but the dates of topping were about a week later. In 1909 the untopped cotton and that topped

August 1 yielded 1,461 and 1,580 lbs. per acre, respectively. In 1907 the cotton topped August 3 yielded 1,808 lbs., as compared with 1,575 lbs. on the check plot, and that topped August 26 yielded 1,780 lbs. as compared with 1,821 on the corresponding untopped or check plot.

Rows 3 ft. apart produced more cotton than those farther apart, in 1911, but were not included in the 1909 test when 4-ft. rows gave greater yields than either 5 or 6 ft. rows. In these tests the plants averaged 15 in. apart in the row. In rows 3 ft. 8 in. apart, plants spaced 12 in. apart gave greater 2-year average yields per acre than those spaced 20 or 30 in. apart.

Poisoning the army worm on August 20 and 30 resulted in a yield of 1,414 lbs. of seed cotton per acre as compared with 767 lbs. on the untreated plots. Paris green appeared to be more effective than arsenate of lead.

II. *Results from the McNiel Experiment Station, E. R. Ferris (pp. 14-21).*—Meteorological data are followed by a statement of the results of a variety test in which Ashcraft Double Jointed Snow Bank, Trice, and Truitt 90-day produced the highest yields.

A table states the 6-year average results secured in a test of various fertilizers. The highest yields were obtained after applications of (1) 100 lbs. each of cotton-seed meal and acid phosphate, and (2) 100 lbs. each of cotton-seed meal, acid phosphate, and kainit. Both plots were on land on which cattle were fed during the winter of 1902-3. On land on which cattle had not been fed the highest yield followed an application of 200 lbs. of cotton-seed meal and 100 lbs. of acid phosphate. Cotton planted April 1 gave 278 lbs. per acre as compared with 289 lbs. from that planted April 15, 55 lbs. from that planted May 1, and a total failure in case of that planted May 15.

III. *Results from the Holly Springs Branch Experiment Station, C. T. Ames (pp. 22-27).*—In a variety test at this station the highest yields of lint cotton per acre were given by Truitt 90-day, Broadwell Double Jointed, and Rowden 116. In the fertilizer test the highest yields followed applications of (1) 200 lbs. acid phosphate (2) 100 lbs. each acid phosphate and cotton-seed meal, and (3) 200 lbs. cotton-seed meal, in the order named. Ten applications were tested in this series of experiments and in a parallel series 7 of them were duplicated except that the applications were doubled in amount. In this series much the highest yield followed the application of 200 lbs. each of cotton-seed meal and acid phosphate. These figures are for 1911. Another table states the 6-year average results in which the same applications were followed by the highest yields but with less distinct advantage. In another fertilizer test in 1911 the highest yields followed applications of (1) 200 lbs. of cotton-seed meal and (2) 400 lbs. of raw-rock phosphate. In a test of nitrogen sources supplemented in each case by 200 lbs. of acid phosphate the use of (1) 200 lbs. of cotton-seed meal and (2) 80 lbs. of nitrate of soda gave yields somewhat higher than those secured from the use of 150 lbs. of nitroline or 486 lbs. of ammoline. The soil used has been in cultivation more than 50 years and is characteristic of the poorer soils of the section.

IV. *Results from Delta Branch Experiment Station, G. B. Walker (pp. 27-29).*—The Express and Triumph varieties excelled the others tested in value of lint cotton per acre.

In a spacing test in which the stalks stood from 18 to 24 in. apart in the row, better yields were obtained from rows  $3\frac{1}{2}$  ft. apart than from rows 3, 4, 5, or 6 ft. apart.

Note on the present position of cotton investigation in India, B. COVENTRY (*Agr. Research Inst. Pusa, Bul. 26, 1911, pp. 11*).—A brief survey of the status of cotton planting, fertilizer, and cultural investigations in India.

[Flax experiments in India], E. M. VANDEKERKHOVE (*Agr. Research Inst. Pusa, Bul. 25, 1911, pp. 11, pls. 4*).—This is a brief report of fertilizer and rate of sowing tests of flax at Dooriah during the year 1910-11.

Ragged Jack kale (*Agr. Gaz. N. S. Wales, 23 (1912), No. 2, p. 183*).—Seed sent from the botanical gardens to the Bathurst experiment farm produced plants which ran to seed as soon as planted, presumably because of the lateness of the season. Seed sent to the Glen Innes farm, however, produced succulent plants entirely devoid of woody fiber, but did not equal white chou moellier in quality of green fodder.

Black oats, A. H. E. McDONALD ET AL (*Dept. Agr. N. S. Wales, Farmers' Bul. 50, 1911, pp. 3-13*).—A discussion of the wild oat (*Avena fatua*), with suggestions on its control and eradication.

Fertilizers and the growth of rice, J. ZAMORA (*Philippine Agr. and Forester, 1 (1911), No. 8, pp. 152-154*).—This article states the result of pot experiments with rice in which the chemically pure salts ammonium nitrate, potassium phosphate, calcium phosphate, magnesium chlorid, magnesium nitrate, and magnesium sulphate were used in molecular solutions. A table states the number of leaves, date of flowering, height of plants, and number of rice grains per plant secured.

Correlation in rye, D. LEHN (*Illus. Landw. Ztg., 32 (1912), No. 3, pp. 13, 14*).—The author presents figures from the records of C. Kraft, who has practiced individual selection from Zeeländer rye for 10 years.

From data for the 4-year period 1908-1911, it appears that the length of haulms varies directly with length of head, number of internodes, weight per head and per 1,000 kernels, and number of kernels per head, while it varies inversely as the weight per plant, the number of haulms, the density of head, the grain weight per plant, and the chaff percentage.

Soy beans, W. F. INGALLS (*Cooperstown, N. Y. [1912], pp. 36, pls. 3*).—This is a brief manual of information for the soy bean grower.

The growth of sugar beet (*Abs. in Jour. Bd. Agr. [London], 18 (1912), No. 11, p. 9/3*).—In a comparative test of sugar beets and mangels at 6 points in Somerset the yields were 16 and 40 tons per acre, respectively. The beets were left a little closer in the drills. Heavy manurial applications tended to depress the sugar percentage of the beets.

Experiments on the cultivation of sugar cane at the Partabgarh Experimental Station, 1909-1911, G. CLARKE ET AL (*Agr. Research Inst. Pusa, Bul. 27, 1912, pp. 29, pls. 2*).—This is largely made up of tables stating the results of rate of planting tests at the Partabgarh station in India during 1909-1911. The author notes that the sugar canes of upper India differ markedly from those of other countries and demand very different treatment, and that the general conclusions holding good for varieties growing in Java, the West Indies, and southern United States can not always be applied to them.

Sweet potato investigation, T. E. KEITT (*South Carolina Sta. Bul. 165, pp. 43*).—Previous work on the sweet potato by the station (*E. S. R., 25, p. 534*) is reviewed, and some general information regarding the crop is presented. Determinations of sugar, glucose, and starch, and studies on the formation of sugars and starch and the content of these substances at different times of harvesting are reported, together with descriptions of the different varieties tested, fertilizer and proximate analyses of different varieties, and a report of an additional laundry test of the starch.

Determinations of samples filtered under pressure showed an average of 4.21 per cent, and samples filtered without pressure an average of 4.22 per cent, of sucrose and glucose together. It was found that some changes took place in

the samples as they stood, the indication being the formation of an acid. To prevent this change, for the purpose of obtaining more accurate results, bichlorid of mercury was used as a disinfectant to arrest enzym action and fermentation, but this was also found to interfere with the accuracy of the method.

The study of the formation of the sugars and starch by analyzing samples harvested on different dates showed that on August 28, 1908, in every case, the sucrose was high and the glucose low, that the sucrose decreased and the glucose increased as the time of maturity approached, and that the total sugars and starch both decreased at the time of the most rapid development. Later the starch increased, but the total sugars continued to decrease, the water decreasing at the same time, until September 29 when the sucrose was at its lowest and the glucose generally at its highest.

Similar work was continued in 1909. The results led the author to believe that in the very immature potato the sugar may be present either as glucose or sucrose, probably depending upon the meteorological conditions. It is stated that in 1908 when the 10 days previous to the first digging were wet and cloudy, the sugar was in the form of sucrose, while in 1909 when the 10 days preceding the digging were fair, it was present almost entirely as glucose. The crop of 1908 was grown on a clay loam soil, while the 1909 crop was grown on a sandy soil.

Crop rotation and fertilizer experiments with sun-cured tobacco, W. W. GREEN (*Virginia Sta. Bul. 196, pp. 3-20, figs. 8*).—Earlier reports on these experiments, which are in cooperation with this Department, have already been noted (*E. S. R., 22, p. 137*).

The results of the crop rotation work led to the recommendation of the following 7-year rotation: Tobacco, wheat, grass, grass, corn with crimson clover as a cover crop, cowpeas, and red clover. The rotation of crops in the sun-cured tobacco district was found necessary and profitable. In connection with this rotation work it was found that seeding grass alone in August gave better results than seeding with small grain.

The fertilizer experiments showed that phosphoric acid was needed most in the soils of the sun-cured tobacco district, and that a complete fertilizer gave the best returns. Potash and nitrogen were unprofitable without phosphoric acid. The use of lime did not respond very perceptibly. Applications of cotton-seed meal made a much finer grade of tobacco than the use of nitrate of soda, but the yield was smaller. Only two-thirds as much nitrogen was found necessary when given in the form of nitrate of soda as when applied as cotton-seed meal. Heavy applications of fertilizer were found to be more profitable than light applications. The use of 1,000 lbs. of 3:8:3 fertilizer per acre gave a profit of \$40.29, while 1,300 lbs. of a home-mixed fertilizer gave a profit of \$112.17.

Growing and curing sun-cured tobacco, W. W. GREEN (*Virginia Sta. Bul. 197, pp. 3-14, figs. 6*).—Directions for growing and curing sun-cured tobacco accompany a statement of the results of a fertilizer test.

A yield of 580 lbs. of tobacco and a profit of \$38.69 followed an application of 1,000 lbs. of a ready-mixed 3:8:3 fertilizer costing \$12.50 as compared with 1,110 lbs. and \$79.92 after an application of a mixture of 1,500 lbs. cotton-seed meal, 500 lbs. of acid phosphate, and 200 lbs. of sulphate of potash per acre costing \$32.41. "This shows more than twice the net returns from the heavy application of home-mixed fertilizer" than were secured after the use of the ready-mixed fertilizer. The following wheat crop also received a marked benefit.

**Crop rotation and fertilizer experiments with bright tobacco.** R. P. COCKE (*Virginia Sta. Bul.* 198, pp. 3-20, figs. 6).—Results similar to those reported have been previously noted, with descriptions of the experiments (E. S. R., 22, p. 137).

The results here reported indicate the value of using a complete fertilizer for bright tobacco. The value of the crop less the cost of the fertilizer when fertilized with nitrogen, potash, or phosphoric acid alone was \$63.43 or less per acre, while it reached \$124.54 per acre where a complete application was used. The use of 1,400 lbs. of a 3:8:3 fertilizer per acre gave a net profit of \$19.58 more than 800 lbs. of the same fertilizer, and the effects on succeeding crops were more pronounced.

The rotation recommended for 6 years is as follows: Tobacco, wheat, grass, grass, corn with crimson clover as a cover crop, and cowpeas. An average yield of tobacco under this rotation of 1,257 lbs. per acre, having a value of \$116.98, was secured. It was found that the use of lime darkened the color of bright tobacco, showed little benefit to corn and wheat, but had a most satisfactory influence on the growth of grass.

**Wheat breeding experiments,** E. G. MONTGOMERY (*Nebraska Sta. Bul.* 125, pp. 5-16, figs. 9).—A historical sketch of wheat culture and wheat-breeding work in Nebraska is followed by a statement of the results of variety tests at the station and of tests of improved strains by farmers.

Tests of over 100 varieties already noted (E. S. R., 14, p. 36) have indicated only 3 varieties that were capable of surviving Nebraska's very dry winters, and as Turkey Red excelled the other 2 varieties in milling qualities it was evidently most suitable for general cultivation. Attempts to improve it by the importation of new seed from southern Russia or from Alberta, Canada, have given negative results. Selection, however, produced strains which varied in ability to resist lodging and in shape and quantity of grain, as well as in yielding power. A table states results secured during the period 1907-1910 from 26 strains. They varied in yield from 28.88 to 40.75 bu. per acre, but it was difficult to tell by appearance the best from the poorest yielders in the field.

In 1910, 26 8-acre fields of improved strains were sown in 20 different counties of the State. The results reported by 21 experimenters showed average yields of 25.9 bu. of the improved Turkey Red as compared with 21.9 bu. of the locally grown Turkey Red. The 3 strains used in this test were Nos. 287, 425, and 48. "No. 48 has proved to be a very satisfactory yielder in comparison, but was reported as somewhat light in color." A fourth strain, No. 42, which is now ready for distribution "appears to be superior to any of the other varieties so far tested, especially in color and quality."

**Is Federation wheat degenerating?** J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 3, pp. 213-215).—An account is given of the occurrence of 3 mutants in Federation wheat and of the crops secured from them. Inquiry indicated that a number of other variations had been observed in this variety at the different experiment farms.

**Twenty five years' plant improvement in Sweden,** N. H. NILSSON (*Sveriges Utsädesför. Tidskr.*, 21 (1911), No. 4, pp. 175-187).—This is a history and explanation of the organization and work of the Swedish Seed Improvement Society.

## HORTICULTURE.

**Radium as a means of forcing plants,** H. MOLISCH (*Österr. Gart. Ztg.*, 7 (1912), No. 6, pp. 197-202, figs. 3).—A summarized account of the author's experiments in the use of radium chlorid and radium emanation in forcing plants,

During the latter part of November lilac branches were successfully forced out by attaching pipettes containing a small quantity of radium chlorid to the terminal buds. The forcing effect was irregular, however, since the individual buds were situated at different distances from the radiating area. Lilac branches exposed to radium emanation for periods of 20, 48, and 72 hours were successfully forced, the longer exposure giving the quicker results. Similar results were secured with chestnut branches, except that exposure to emanation for a day appeared to be sufficient. Tests were also made with branches of a number of other trees. The tulip, bladdernut, and maple were successfully forced, whereas the ginkgo, sycamore, red beech, and linden gave negative results. The experiments indicate that radium emanation will only stimulate growth during that part of the rest period between the middle of November and the end of December.

New garden plants of the year 1911 (*Roy. Bot. Gard. Kew. Bul. Misc. Inform., 1912, App. 3, pp. 39-64*).—A list is given of garden plants described in botanical and horticultural publications during 1911. It comprises all the new introductions recorded, together with the most noteworthy of those which have been reintroduced after being lost from cultivation.

Report of the division of horticulture of the Central Agricultural Station for the year 1911, M. CALVINO (*Estac. Agr. Cent. [Mexico] Bol. 66, 1912, pp. 82, pls. 74*).—This comprises a report of varietal, climatal, and cultural experiments with forage crops, fruits, rubber trees, rubber vegetables, ornamentals, and cereals conducted at the Central Agricultural Station.

Home gardening in South Carolina, C. C. NEWMAN (*South Carolina Sta. Bul. 166, pp. 3-48, figs. 6*).—A popular treatise presenting general considerations relative to soil and plant classification, how plants feed and grow, crop rotation, cultivation, fertilizers, hotbeds and cold frames, and giving specific directions for the culture of the important vegetables. Directions are given for controlling the more troublesome insects and fungus diseases, together with planting tables and varieties of vegetables recommended for the home garden in South Carolina.

Growing Denia onion seed, F. GARCÍA (*New Mexico Sta. Bul. 82, pp. 27, figs. 8*).—In a previous bulletin (*E. S. R., 22, p. 732*) it was shown that the Spanish or Denia onion is well adapted for culture in certain parts of New Mexico.

Successful experiments in the production of a home supply of Denia onion seed are here reported. The seed was produced at the rate of 525 lbs. per acre in 1910 and 430 lbs. per acre in 1911. The germination tests showed 89 per cent and 81 per cent for the 2 years, respectively. The onions raised from the home-grown seed compare favorably with those from imported seed.

Impediments to the vegetable industry and their control, J. KINDSHOVEN (*Flugschr. Deut. Landw. Gesell., 1912, No. 13, pp. 26*).—This comprises a popular treatise on the control of plant diseases, animal pests, and other drawbacks to successful vegetable growing.

Pomology (*9. Cong. Internat. Agr. Madrid, 1911, pp. 639-715*).—This comprises reports of papers presented and discussed in the pomological section of the Ninth International Congress of Agriculture, Madrid, in 1911, as follows: The Culture of Oranges, Olives, and Other Important Fruit Trees, by J. M. P. Jaramillo; a report on the same theme, by Janini; Suggestive Improvements in the Culture of Olives and the Manufacture of Olive Oil, by J. Chapelle; Methods of Defense against the Parasites and Principal Diseases of Fruit Trees, by L. Navarro; reports on the same theme, by L. Salas Amat and R. Janini; Recent Progress in the United States against Insects Destructive to Oranges, by C. L. Marlatt; and The Ink Disease in Chestnut Groves at Ardèche, by J. Farcy.

**Fruit culture**, R. GOETHE (*Obstbau. Berlin, 1910, pp. 174, pls. 30, figs. 77*).—A practical treatise on fruit growing with special reference to German conditions.

**How to grow and market fruit** (*Berlin, Md. [1912], pp. 131, pls. 24*).—A practical treatise on fruit culture and marketing.

**The California fruits and how to grow them**, E. J. WICKSON (*San Francisco, Cal., 1912, 6. ed., rev., pp. 602, figs. 181*).—The present edition of this treatise (E. R. S., 22, p. 734) has been revised with a view to including recent progress in various phases of the fruit industry.

**Experiments on the pollination of our hardy fruits**, C. H. HOOPER (*Irish Gard., 7 (1912), Nos. 76, pp. 83, 84; 77, pp. 102, 103*).—A summarized account of this work has been previously noted (E. S. R., 25, p. 338).

**Orchard heating**, L. GREENE (*Iowa Sta. Bul. 129, pp. 131-164, figs. 16*).—This bulletin reports tests conducted by the station in 3 different orchards during the season of 1911 to determine the value and efficiency of some of the orchard heating devices now on the market. Reports from individual growers in various sections of the State, who also tried out heating devices, are included and general information is given relative to methods of heating orchards.

The spring of 1911 did not offer the best conditions for a thorough test because injurious temperatures did not occur.

**How a Ventura lemon grove was protected**, C. A. TEAGUE (*Pacific Rural Press, 83 (1912), No. 26, pp. 604, 605*).—A detailed statement is given of frost fighting experience during the past season in a California lemon grove.

**New heater and vaporizer for frost protection**, A. G. MCADIE (*Mo. Weather Rev., 40 (1912), No. 4, pp. 618, 619*).—A new heater and vaporizer being tried at the San Francisco office of the Weather Bureau is here described.

**Temperatures injurious to peaches, apples, and pears in various stages of development** (*Mo. Weather Rev., 40 (1912), No. 3, p. 426*).—This comprises data collected under the direction of the Fruit Growers' Association of the Grand Valley, Colo., with the view of assisting growers in frost protection work.

**Tests of summer sprays on apples, peaches, etc.**, G. P. CLINTON and W. E. BRITTON (*Connecticut State Sta. Rpt. 1911, pt. 5, pp. 377-406, pls. 8*).—Tests of various Bordeaux, lime-sulphur, and miscellaneous sulphur mixtures (E. S. R., 24, p. 553) were continued on an extended scale in 1911. Lead arsenate was used, both with the mixtures and alone, as an insecticide. The details of the year's work with apples, peaches, pears, quinces, plums, cherries, and currants are reported and the results of the 2 years' work with apples and peaches are reviewed. With the results secured in the above experiments as a basis recommendations are given as to spraying practice for these fruits.

In these experiments Bordeaux has on the whole shown the best fungicidal value of any of the sprays tried. In the work with apples it was found that 3 sprayings having lead arsenate in the last 2 keep most of the fungi and insects under control. In the control of black rot on the leaves complete removal of the diseased branches should be combined with spraying. The prevention of rust requires a continuous coating of the leaves from the time they first appear until all danger of infection from the cedar apple stage is over. To reduce the russetting or burning of apples that occurs with Bordeaux used alone, the authors advise using the 4:4:50 formula in the first spraying before the blossoms have opened at the critical time for scab. In the second and third spraying a 1:4:50 formula may be used. Compared with the commercial lime-sulphur sprays, however, even weak Bordeaux is apt to produce more russetting on such susceptible varieties as Baldwin and Greening. The authors are not yet prepared to recommend a substitution of lime-sulphur solutions for Bordeaux

on those varieties not seriously liable to russetting or on those very susceptible to fungus attack. The varieties which were found to be either immune or susceptible to scab, rust, sooty blotch, fruit specks, and rot are indicated. Taking all things into consideration, including the difficulty of making self-boiled lime-sulphur, this mixture appears to have no special advantage over the commercial lime-sulphurs as a fungicide for apples.

When commercial lime-sulphur is substituted for Bordeaux it should be used at the rate of  $1\frac{1}{2}$  gal. per 50 gal. of water for all 3 sprayings. For the insecticide lead arsenate at the rate of 3 lbs. of paste or  $1\frac{1}{2}$  lbs. of powder per 50 gal. of mixture may be added in the last 2 sprayings. The treatment recommended for the pear and quince is similar to that for the apple. For peaches, cherries, and plums, where there is always danger of burning from Bordeaux and also often from commercial lime-sulphurs, especially if used with lead arsenate, self-boiled lime-sulphur appears to be the best fungicide since it produces on the whole the least injury of any spray tried. The 8:8:50 formula for all 3 sprayings has given the best results.

In the 2 years' work with peaches lead arsenate has done little to prevent the attacks of curculio, and since it seems to increase the danger of spray injury when combined with lime-sulphur, the authors advise leaving it out unless there is considerable danger from sawfly injury, when it can be added in the second spraying as with apples.

Orchard spraying experiments, W. W. BONNS (*Maine Sta. Bul.* 198, pp. 32, pls. 5).—Spraying experiments were continued at the Highmoor Farm in 1911 (E. S. R., 25, p. 538), and cooperative experiments were conducted in 3 nearby orchards. The formulas used in the Highmoor experiments included lead arsenate at the rates of 2 lbs. and 4 lbs. to 50 gal. of water, lime-sulphur at the rates of  $1\frac{1}{2}$ ,  $1\frac{3}{4}$ , and 2 lbs. to 50 gal. of water, plus 2 lbs. of lead arsenate in each case, and Bordeaux mixture 3:3:50 plus 2 lbs. of lead arsenate. The results are presented in detail and discussed.

Seasonal conditions combined with other inhibitive factors were unfavorable for the development of fungus and insect injury to any practical degree, hence no valuable data for estimating the fungicidal or insecticidal value of the sprays were secured. In the case of fruit russetting none of the percentages from any plats were high and all so nearly alike that no deductions are warranted. The relation of lime-sulphur injury to strength of solution was not indicated in any way.

In view of observations made in 1911 the author is now inclined to the opinion that calyx injury, which was found quite generally on fruit sprayed with lime-sulphur in 1910, may be due as much to lack of vigor in the tree as indicated by the tissues of the fruit, as to the caustic action of the spray.

A form of injury known as sunscald was produced by sunlight on fruit directly exposed to the sun upon the southern sides of trees. The sunscald appeared as discolored sunken spots or maculations with a sharply defined margin. Spraying during hot weather appeared to increase the severity of sunscald where injured areas were present before the last spray was applied. Also the amount of scald, though relatively small, varied directly with the strength of lime-sulphur used. Injury on the lead-arsenate plats was less in amount but qualitatively equally serious. Scald injury on the Bordeaux plats was very slight.

Aside from fruit russetting a large percentage of the apples on the Bordeaux plat showed more or less Bordeaux injury, the fruit appearing to be either well mottled with dull-brown flecks a few millimeters in diameter or speckled with minute dots. This gave to the fruit a general soiled dull-brown hue. The coloring of the fruit from this plat was far below that of the apples on any of

the others, whereas the fruit of the other experimental plats, benefited by the rains of late summer and the long period of sunshine, grew to unusual size and was of exceptionally high quality and color. The development of Bordeaux injury appears to have coincided with a period of rainy weather.

From the results of the experiments as a whole the author concludes that spray injury may be, and very likely is, due as much to a physical factor, i. e., the application of a mist or spray to growing plant tissues under extreme, or some now undetermined, but unfavorable, meteorological conditions, as to any chemical action of the material used.

**Analyses of materials sold as insecticides and fungicides** (*New York State Sta. Bul.* 348, pp. 85-98).—Analyses are reported of Paris green, lead arsenate, Bordeaux lead arsenate, Bordeaux mixture, Bordeaux-Paris green mixtures, lime-sulphur solutions, mixtures of soluble sulphur and oils, nicotin preparations, soap solutions, sulphur, and hellebore.

**The precooling of fruit in the United States.** S. J. DENNIS (*Ber. II. Internat. Kältenkong. Wien, 2 (1910), pp. 434-456, figs. 8*).—A paper on this subject read before the Second International Refrigeration Congress, held at Vienna in 1910.

**Refrigeration in relation to fruit growing in Canada.** J. A. RUDDICK (*Ann. Rpt. Fruit Growers' Assoc. Nova Scotia, 48 (1912), pp. 33-42*).—In this paper the author points out some of the possibilities of cold storage in relation to the fruit industry.

**Breeding citrus trees.** A. D. SHAMEL (*Pacific Rural Press, 83 (1912), No. 25, p. 589*).—An abstract of a paper read before the California State Fruit Growers' Convention at Santa Barbara.

In his study of bud selection with citrus fruits (*E. S. R., 24, p. 737*), the author finds frequent variation in type of tree and fruit such as would come under the heading of bud sports or so-called bud mutation. A study of one grove of Washington navel oranges of about 150 acres revealed the presence of 7 frequently occurring types, 5 of which are unproductive, bearing low-grade undesirable and unprofitable fruit. All of the trees of this grove were propagated from the 2 parent Washington navel trees in Riverside. Similar variations were found in grapefruit and lemons. The frequency and general prevalence of bud sports in the Valencia orange is much greater than in any citrus variety yet studied.

The trees have been found to vary consistently, not only in striking typical differences, but in the amount of production within the type. About 10 per cent of standard type trees studied are consistent producers of the highest grades of fruit and free from any evidence of bud sports. The author calls attention to the successful results secured by G. T. Powell from the practice of careful bud selection (*E. S. R., 19, p. 1142*), and offers a general conclusion that a careful study of bud variation and bud selection will prove of great benefit to the growers of all plants propagated by budding.

**Work for citrus improvement.** J. E. COIT (*Pacific Rural Press, 84 (1912), No. 1, pp. 5, 6*).—This comprises a brief sketch of the plan of development of the work of the California Citrus Substation.

**Viticulture** (*9. Cong. Internat. Agr. Madrid, 1911, pp. 587-637*).—This comprises the following papers presented and discussed in the viticultural section of the Ninth International Congress of Agriculture, Madrid, 1911: Grape Stocks Best Adapted to Dry and Limy Soils, by N. García de los Salmones (*E. S. R., 27, p. 145*); The Grape Stocks in Dry and Limy Soils, by P. Gervais; and New Phases in the Utilization of Musts and Wines, by C. Mestre Artiga.

[**Report of the viticultural branch**], M. BLUNNO (*Rpt. Dept. Agr. N. S. Wales, 1911, pp. 60-64*).—This report is largely a review of the work of recon-

stituting phylloxera-infested vineyards with resistant stocks, together with a review of the 1911 vintage and enochemical analysis.

A new process of grafting American grapes, P. BUNERT (*Möllers Deut. Gärt. Ztg.*, 27 (1912), No 24, pp. 277, 278, figs. 2).—The method described consists of the use of a plaster of Paris bandage around the union and rooting the grafted cuttings without artificial heat.

Making a rock garden, H. S. ADAMS (*New York, 1912, pp. 52, pls. 8, figs. 6*).—A short treatise on the details of constructing and plant materials for rock, wall, water, and bog gardens.

Making a garden to bloom this year, GRACE TABOR (*New York, 1912, pp. 54, pls. 8, fig. 1*).—A popular discussion of plant material for quick effects.

## FORESTRY.

Illustrated key to the wild and commonly cultivated trees of the northeastern United States and adjacent Canada, based primarily upon leaf characters, J. F. COLLINS and H. W. PRESTON (*New York, 1912, pp. VII+184, figs. 279*).—The authors' Key to New England Trees (*E. S. R.*, 21, p. 241) has been extended in the present handbook to include the northeastern States and adjacent Canada. Illustrations showing an outline of a typical leaf of every tree of which the leaves differ sufficiently to be easily recognized have also been included.

Key to the wild and cultivated trees in autumn, C. A. DARLING (*Torreya, 12 (1912), No. 7, pp. 155-164*).—This key is designed to be used in the field to determine the trees to be found growing in the eastern United States.

The seedlings of the live oak and white oak, W. C. COKER (*Jour. Elisha Mitchell Sci. Soc.*, 28 (1912), No. 1, pp. 34-41, pls. 2).—A comparative study of the seedling structure of live and white oaks, with special reference to the tuberous formations of the roots of live oak seedlings.

Tulipwoods and tulip trees, W. DALLIMORE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1912, No. 5, pp. 241-245).—Descriptive accounts are given of a number of woods which are commonly classed as tulipwood.

Eucalyptus, its history, growth, and utilization, C. H. SELLERS (*Sacramento, Cal., 1910, pp. 93, figs. 35*).—This is a treatise on eucalyptus culture, based largely on data secured from various groves in California. Information is given relative to the soil and climatic requirements, adaptability of species for given localities, time and method of planting, and subsequent care and management. Considerable data are also given relative to the rate of growth, yield, and utilization of the different species.

Camphor from *Cinnamomum camphora*; cultivation and preparation in the Federated Malay States, B. J. EATON (*Dept. Agr. Fed. Malay States Bul.* 15, 1912, pp. 38, pl. 1).—In addition to a description of the experiments carried out in the Federated Malay States Agricultural Department, a summary is given of experiments conducted in other countries, together with a résumé of the present condition of the industry.

[Rubber tapping experiments], H. NEWPORT (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1909-10, pp. 67-74*).—This comprises a detailed statement of experiments in tapping Para rubber, together with estimates of the cost of establishing, upkeep, and the profits to be derived from a Para rubber plantation.

The woodlot for central Indiana, E. C. PEGG and M. B. THOMAS (*Proc. Ind. Acad. Sci.*, 1909, pp. 419-439, figs. 4).—This paper describes the condition of central Indiana woodlots and makes suggestions for their improvement and perpetuation.

**Wood-using industries and National Forests of Arkansas** (*U. S. Dept. Agr., Forest Serv. Bul. 106, pp. 49*).—This is a 2-part bulletin dealing with the forest products and resources of Arkansas.

Part I. *Uses and supply of wood in Arkansas*, J. T. Harris and H. Maxwell (pp. 7-26).—This comprises a statistical account of that part of the sawmill output which passes through further processes of manufacture in the State. Tabular data are given showing the amount of such wood consumed annually in Arkansas by species and industries, together with the cost and the percentage grown in and out of the State. The various woods included are briefly described.

Part II. *Timber resources of the National Forests in Arkansas*, F. Kiefer (pp. 27-36).—This describes the various kinds of timber on the National Forests and the means of purchasing it.

Grades and specifications of rough stock and squares employed in making special hardwood products for factory use, together with a summary of uses of wood by Arkansas manufacturers are appended to the bulletin.

**Forest products of Canada, 1911.**—Pulphwood, H. R. MacMILLAN, E. G. McDougall, and W. G. H. Boyce (*Dept. Int. Canada, Forestry Branch Bul. 30, 1912, pp. 17, figs. 3*).—A statistical account of the quantity and value of the pulp wood produced in Canada, reported by species, Provinces, and processes. Data are also given showing the pulp exported from the Dominion, together with the pulp wood exported from the various Provinces in a manufactured state. The 54 firms reporting used 672,288 cords in 1911 and 847,939 cords were exported in the raw state.

**Strength tests of cross-arms**, T. R. C. Wilson (*U. S. Dept. Agr., Forest Serv. Circ. 204, pp. 15, figs. 2*).—This circular describes tests of Douglas fir, shortleaf pine, longleaf pine, and southern white cedar cross-arms, conducted at the Forest Products Laboratory, Madison, Wis.

The average maximum load borne by the various species and grades ranged from 10,180 lbs. for longleaf pine with 75 per cent heartwood to 5,200 lbs. for white cedar, the weakest wood used. Inasmuch as the poles have not withstood an average side pull of much more than 3,000 lbs., all of the woods tested are considered sufficiently strong to be used for cross-arms.

**The preservation of mine timbers**, E. W. Peters (*U. S. Dept. Agr., Forest Serv. Bul. 107, pp. 27, pls. 4, figs. 7*).—Experiments conducted cooperatively by the Forest Service and various mining companies throughout the United States to secure authentic data on the efficiency of various methods of preserving mine timbers from decay, in continuation of previous work (E. S. R., 19, p. 545), are here reported. The work is discussed under the general headings of agencies destructive to mine timbers, practical methods of increasing the durability of timber, results of experimental treatments, cost of treatment, durability of treated timbers, economy in the use of treated timber, and the avoidance of waste. Analyses of preservatives are appended.

Decay was found to be the agency most destructive to timber used in mines. Although this may often be retarded by peeling and seasoning, treatment with a suitable preservative is more effective. Mine timbers impregnated with zinc chlorid and creosote oils have shown the best results. Green, unpeeled, and untreated loblolly pine gangway sets lasted less than 1½ years. Brush treatments with creosote and carbolineum increased the average life about 3 or 4 years, while impregnation treatments with zinc chlorid and creosote left from 70 to 90 per cent of the timbers sound at the end of 4 years. Either the brush treatment, the open tank process, or the pressure process may be used in treating mine timbers, the method employed depending on the amount of material to be treated.

Silviculture (9. Cong. Internat. Agr. Madrid, 1911, pp. 507-586).—This comprises the following papers on reforestation presented and discussed in the silvicultural section of the Ninth International Congress of Agriculture, Madrid, 1911: Reforestation, Its Advantages and Methods Affecting It, by C. de Camps; Reforestation, by Daubrée; The Problem of Reforestation in the Mediterranean Basin, by R. Hickel; Value of Reforestation and Methods of Accomplishing It, by P. Descombes; The Work of Official Corporations, Societies, and Individuals in Connection with Reforestation in Spain, by R. Codorniú; Principles of Reforestation in Denmark, by C. Dalgas; Value of Reforestation and Methods of Accomplishing It, by A. Mendès d'Almeida; Reforestation, by M. L. de Vilmorin; and Protection and Surveillance of Trees, by Fuensanta de Palma.

On the influence of various degrees of light and extreme temperatures upon the germination of forest seed, G. PITTAUER (*Centbl. Gesam. Forstw.*, 38 (1912), Nos. 4, pp. 157-172; 5, pp. 213-224, figs. 2).—Experiments conducted with spruce, larch, white, black, and Weymouth pine, locust, and red beech seeds are reported in detail.

The selection strip-felling and its system, C. WAGNER (*Der Blendersaumschlag und sein System. Tübingen, 1912, pp. XII+368, pls. 2, figs. 73*).—A treatise on forestry in which the author sets forth a system of forest management based on the selection strip method of felling discussed in his previous work, *The Principles of Spacial Arrangements in Forests* (E. S. R., 20, p. 645).

The lightning danger of various trees, E. STAHL (*Die Blitzgefährdung der Verschiedenen Baumarten. Jena, 1912, pp. 75*).—This comprises an examination of both scientific and popular literature dealing with the value of various tree species as lightning conductors.

Summing up the evidence as a whole it does not appear that trees are of material value as lightning conductors near buildings or that they are sufficiently dangerous to be abolished from the vicinity of a building. A comparative study of the characteristics of those trees which have been reported most dangerous and those which have been reported least dangerous shows a tendency for certain trees to become quickly wet from top to bottom during an ordinary thunder shower. To this class of trees, which forms the best lightning conductors, belong the apple, cherry, nut trees, beeches, horse chestnut, hornbeam, maple, and sycamore. The greatest loss of life and damage to property has been caused by such trees as spruce, firs, larches, poplars, willows, elms, linden, ash, pear tree, and oaks.

Forest fire protection under the Weeks law in cooperation with States, J. G. PETERS (*U. S. Dept. Agr., Forest Serv. Circ. 205, pp. 15, fig. 1*).—This circular explains the nature of the aid rendered by the Forest Service of this Department under section 2 of the Weeks law (E. S. R., 24, p. 498), which section authorizes the Secretary of Agriculture to cooperate with States in protecting from fire the forested watersheds of navigable streams.

A review is given of the work done in 1911, together with the results accomplished. The form of agreement for cooperative work, together with a sample fire plan map of the northern district of New Hampshire, is appended.

Eighth annual report of the state forester of Massachusetts, F. W. RANE (*Ann. Rpt. State Forester Mass.*, 8 (1911), pp. 154, pls. 8, figs. 3).—Introductory considerations deal with the organization and staff of the forestry department. Part 1 reviews the general forest operations for the year, including the examinations of woodland and assistance rendered to owners, reforestation and forest nursery work, forest fires and methods of control, progress of the chestnut bark disease in Massachusetts, a sketch showing a proposed cure for the lumbering slash evil, numerous addresses and lectures delivered by the state for-

ester, and new forestry legislation, together with a financial statement for the year. A state-wide forest fire organization, headed by a state warden, was perfected during the year.

Part 2 of this report, which records the year's progress in the suppression of the gipsy and brown-tail moths, is noted on page 455 of this issue.

**Progress report of forest administration in the Andamans for 1910-11.** H. A. FARRINGTON (*Rpt. Forest Admin. Andamans, 1910-11, pp. IV+37*).—This comprises a review of the administration of the state forests of the Andamans, including a financial statement for the year 1910-11. The more important data relative to areas, surveys, protection and miscellaneous forest work, revenues, expenditures, etc., are given in appendixes.

### DISEASES OF PLANTS.

**Four new fungus diseases in Iowa.** L. H. PAMMEL and CHARLOTTE M. KING (*Iowa Sta. Bul. 131, pp. 199-221, figs. 14*).—Notes are given on timothy rust (*Puccinia phlei-pratensis*), alfalfa rust (*Uromyces striatus*), blister canker of the apple (*Nummularia discreta*), and onion smut (*Urocystis cepulae*). The different fungi and their methods of attack are described, and accounts are given on the distribution of the diseases and the relation of the fungus to the host plant, together with suggestions for their control. A bibliography is appended.

**Notes on fungus diseases.** J. C. MOORE (*Rpts. Bot. Sta. [etc.] St. Lucia, 1910-11, pp. 6, 7*).—Brief accounts are given of diseases affecting a number of economic plants, among them the root disease, which attacks cacao, breadfruit, avocados, and other trees; the pink disease of guavas, due to a fungus which has been identified as *Corticium larc*; and a fungus disease of lime branches, which is caused by attacks of *Thelephora pedicellata*.

**Fungi exotici: XIII.** G. MASSEE (*Rep. Bot. Gard. Kew, Bul. Misc. Inform., 1912, No. 4, pp. 189-191*).—The author describes a number of species of fungi, two of which are considered to be injurious parasites. These are *Pheugella hevea*, which is found on the bark of the young Hevea rubber trees in Southern Nigeria, and *Colletotrichum uccator*, which is said to cause the fruit of peppers to become blackened and shriveled. Technical descriptions of the different species are given.

**The seed treatment of summer grains.** L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 10 (1912), No. 2-3, pp. 23-26*).—The author recommends treating oats, barley, and wheat with a 0.1 per cent solution of formalin for the prevention of loose smut of oats, stinking smut of wheat, and barley smut due to *Ustilago hordei*. Other efficient treatments recommended are the use of Sublimoform and Cuproform, combinations of corrosive sublimate and formalin and copper sulphate and formalin. For the treatment of rye a weak solution of corrosive sublimate is preferred. For combating loose smut of wheat and barley chemical treatments can not be recommended, but the modified hot-water treatment is said to be very efficient.

**Control of grain smuts.** JOHANNA WESTERDIJK (*Cultura, 23 (1911), No. 280, pp. 558-598*).—This is a discussion of the present state of the information regarding combating of smut in grains, and of the recent literature on the subject. Attention is given more particularly to the contributions of O. Appel and E. Rheim (*E. S. R., 26, p. 546*) on the treatment with hot air and hot water under conditions claimed by them to produce the best results. The author states that this treatment has already been successfully employed in the Netherlands.

**Cotton anthracnose, H. W. BARRE** (*South Carolina Sta. Circ. 1, pp. 3*).—This circular gives a survey of the situation in South Carolina in relation to the cotton anthracnose, describes the symptoms of the disease and methods for combating it, and requests information from planters in relation to various factors of distribution and control.

**Cotton anthracnose, H. W. BARRE** (*South Carolina Sta. Bul. 164, pp. 22, pl. 1, figs. 6*).—The author has for a number of years been conducting investigations on cotton anthracnose, the technical results of which have been published in the reports of the station (E. S. R., 26, p. 647). The present bulletin brings together in a nontechnical form the information gained to date. The author shows that the disease is spread principally by infected seed and that the fungus retains its vitality in diseased seed for probably 2 years or more. In the field the fungus does not remain alive for more than 1 year. It is claimed that crop rotation and seed selection will control this disease, which is widely spread and very destructive.

**Investigations on potato diseases (third report), G. H. PETHYBRIDGE** (*Dept. Agr. and Tech. Instr. Ireland Jour., 12 (1912), No. 2, pp. 334-359, pls. 3*).—This report gives an account of further studies on various diseases of the potato and means for their control (E. S. R., 25, p. 454). Among the diseases investigated were the ordinary potato blight, sclerotium disease, black stalk rot, corky or powdery scab, leaf curl, leaf roll, sprain, and a new form of potato rot.

In spraying experiments for the potato blight, due to *Phytophthora infestans*, Burgundy mixture, Bordeaux mixture, and lime-sulphur solution were compared. On account of the difficulty of obtaining good lime the Burgundy mixture is given preference over Bordeaux mixture. The lime-sulphur solution was found practically useless in warding off potato blight.

For the sclerotium disease, due to *Sclerotinia sclerotiorum*, no efficient method of treatment has been found, though spraying and cultural methods were tested.

The effect of heating tubers infected with the organism of the black stalk disease (*Bacillus melanogencus*) for 4 hours at 50° C. was tested but without any striking results. When the tubers were subjected to lower temperatures the rot seemed to be accentuated.

The author definitely establishes the fact that *Spongospora subterranea*, the cause of the corky or powdery scab, produces galls on the roots of the potato plant. Soil fungicides were found to reduce the injury due to this organism.

Attention is called to the differences between leaf curl and leaf roll of the potato.

A new tuber rot was investigated which the author states can not be classed as a wet or a dry rot, as it does not exhibit the characteristics of either. The disease occurs in a number of regions in Ireland. It attacks the larger tubers and may cause serious losses in the crop. A study of material demonstrated that it was not due to bacteria, while a fungus was isolated from some of the diseased tubers which is believed to be the cause of the rot. The fungus resembles *P. omnicora*. This form of tuber rot is to be investigated further.

**The Alternaria blight of ginseng, H. H. WHETZEL** (*Spec. Crops, n. ser., 11 (1912), No. 117, pp. 91-95*).—The Alternaria blight, due to *A. panax*, is said to be the most common, widespread, and best known disease of ginseng. It is reported as occurring quite widely throughout the United States, practically in every region where the plant is grown. The symptoms of the disease and the life history of the parasite are described at some length and suggestions given for its control.

According to the author, great care should be exercised to exclude the fungus from the ginseng garden, as its eradication after once becoming established is

practically impossible. The use of a 3:3:50 Bordeaux mixture has proved beneficial both in laboratory tests and when sprayed upon plants. Lime sulphur, which has been tested as a possible substitute for Bordeaux mixture, appeared to be injurious when applied at a strength sufficient to kill the spores of the fungus.

**Leaf-roll disease of potatoes, IV,** O. REITMAIR (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 1, pp. 1-106).—This is the fourth report by the committee on the study of this disease (E. S. R., 27, p. 351), the principal conclusions in which are as follows:

The primary potato leaf-roll disease entails on the plants alterations which affect both plant and tuber, and tend toward a rapid deterioration of the stock. This deterioration through successive generations is accelerated by unfavorable life conditions, but it may be checked or for a time reversed in part by very favorable treatment, the plants meanwhile showing improvement as regards plant development and crop production. Deterioration under favorable conditions is very gradual, but the investigators are not able to report any means of permanently checking the advance of the disease when once established. The question as to whether plants descended from those showing the primary stage of leaf-roll disease are more susceptible to new disease influences is regarded as still unsettled.

The outward indications of deterioration show in varying degree with different varieties of potatoes. Among the sorts now common *Magnum Bonum* seems to most readily acquire this disease. With this variety the investigators were unable even by selection to check the decline of the stock.

The size of the tubers is said to be no criterion of freedom from this disease or of desirability in other respects for seedling purposes.

Observations do not appear to bear out the assumption that inheritance of the disease through the tubers is due to an organism. It appears that along with one primary stage two secondary stages occur, viz. a fungus-free stage resulting from simple inheritance and a fungus-bearing form due to repeated infection. The authors were not able by any treatment of the potatoes to produce therein the characteristic symptoms of the leaf-roll disease.

**Leaf roll of potato,** G. KÖCK and K. KORNAUTH (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 3, pp. 179-247, fig. 1).—This is the fifth report of the committee (see above) and includes studies carried on by the authors for about 3 years on different varieties of potatoes.

Potato leaf roll is held to be a parasitic disease, apparently caused by a fungus of the genus *Fusarium*. This vegetates in the plant attacked, causing the first stage of the disease. Early in its course this fungus may pass into the newly formed tubers or else, through its weakening influence on the aerial portions of the plant, simply produce a crop diminished in size and number of tubers. Subsequent crops produced from these infected or simply lightened or weakened potatoes will show the fungus-bearing or the fungus-free forms, respectively, of the secondary stage of the disease. It was not found practicable to estimate the intensity of the infection with any accuracy from the effect on the crop.

The variety *Magnum Bonum* is said to be very susceptible to the disease, and the deterioration through the successive generations was in this case exceptionally rapid. However, it is considered not to have been conclusively shown that careful selection and favorable treatment on uninfected soil may not check the decline and even show actual improvement.

An important rôle is thought to be played by the soil in the transmission of this disease from the old to the new plants. The question as to the duration of the danger period as regards soil infection and that as to the possibility of limiting or preventing such infection are regarded as still unsettled.

The authors append to this report of their own investigations brief abstracts of a long list of contributions made by others on the subject of potato leaf-roll disease in 1911.

**Experiments with Bordeaux mixture as a cane dip, A. H. ROSENFELD** (*Internat. Sugar Jour.*, 14 (1912), No. 161, pp. 255-263).—The author describes experiments in dipping sugar cane in Bordeaux mixture for the prevention of diseases, and also the effect of the fungicide on the germination and growth of the plants. The experiments were divided into 2 series in which normal strength and double strength Bordeaux mixture was used, one lot of seed cane in each series being left in the solution for 1 hour and the other lot soaked for 24 hours. The cane was planted and observations made on its germination and subsequent growth from time to time.

Inspection showed that cane which had been dipped for 1 hour in the Bordeaux mixture gave better results than the untreated lot, while that which had been soaked for 24 hours in the fungicide gave yields less than the checks. The smallest number of stalks per row was obtained from the lot dipped for 24 hours in double strength Bordeaux mixture.

**Fruit trees and black spot canker, J. F. CARPENTER** (*Brit. Columbia Dept. Agr. Bul.* 34, 1911, pp. 14, figs. 5).—This disease, known also under the names anthracnose, sour sap, etc., in British Columbia since 1901 and in neighboring portions of the United States 10 years earlier, is here described, and the comparative susceptibility of several varieties of trees is discussed.

The disease is said to be due to a parasitic fungus, called *Macrophoma curvispora* by Peck and *Gloeosporium malicorticis* by Cordley. Spore-bearing pustules on the surface mark the course but not the full progress of the disease. The fungus may enter apparently without previous breaches in the bark, but is favored by such injury and spreads in the cambium layer and later in the bark to a corresponding extent, producing broad, deep, and sometimes incurable wounds, sapping the vitality of the trees, killing branches, stunting growth, and materially decreasing crop returns. The spores are contained in a gelatinous mass which dissolves in water, permitting their escape, but not to any very great extent until wet weather furnishes favorable conditions, usually after the appearance of the autumn rains. It seems that infection occurs most freely during November and December.

For control of this disease, comparative dryness and freedom from injury are desirable. Proper elevation, drainage, spacing, pruning, and care in cultivation are insisted upon. To prevent infection of the trees by spores when present, Bordeaux mixture or lime-sulphur wash is recommended. The spraying should be done once early in the fall before the rains set in, and repeated just after the fall of the leaves.

**A new canker-producing fungus, A. POTEBNIA** (*Ztschr. Pflanzenkrank.*, 22 (1912), No. 3, pp. 129-148, pls. 3).—A disease of *Pyrus paradisiaca* was investigated by the author and by him attributed to the activity of a fungus formerly known under the name *Phacidium discolor* but by the author classed as a new genus and named *Phacidella discolor*. A detailed discussion is given of the forms, habits, relationships, and ravages of this fungus, which is found on both dry and living twigs of several species of *Pyrus*, having been noted at Kharkof, Russia, and at Liege, Belgium.

**Diseases of raspberry and loganberry** (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, pp. 124-126, pl. 1).—A description is given of *Hendersonia rubi*, which is responsible for serious injury to raspberries and loganberries, and *Ascochyta pallor*, which occurs as a parasite of raspberries, roses, etc.

The first fungus attacks the stems during the summer when the young growth is tender, and as a rule lurid red or purplish patches appear on the stem.

When several diseased areas are present the canes are killed outright during the winter, whereas when only one or two infected areas are present the canes may survive and produce a certain amount of fruit. Infection mostly takes place during the fruiting period, hence spraying can not be successfully resorted to unless the fruit is sacrificed. If spraying is found desirable the use of Bordeaux mixture is recommended. All diseased canes should be cut out and burned as soon as noticed, and the practice of allowing dead canes to remain standing throughout the winter is condemned.

The second fungus forms white patches on the stems, studded with black dot-like fruits. For the control of this parasite, treatment similar to that suggested for *H. rubi* is recommended.

Invasions of downy mildew in southwest France in 1911, J. CAPUS (*Rev. Vit.*, 37 (1912), No. 958, pp. 568-571).—A detailed account is given of the author's observations made on the 7 outbreaks and the progress of grape mildew in the vineyards of Gironde from June to September, 1911.

Conditions for development of downy mildew.—Temperature, L. RAVAZ and G. VERGE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), No. 16, pp. 485-488).—The authors report on a continuation of their studies (E. S. R., 27, p. 49).

Both young and mature leaves of grapes were inoculated at from 7 to 14° C. with spores in a very moist atmosphere, the controls ranging from 18 to 35°. It was found that the inoculations at temperatures down to 8° showed conidiphores in from 4 to 5 days, but those at 7° failed to develop the infection.

Experiments to determine the danger period from possible infection were also carried out under varied conditions. Conidia on glass plates in a very moist atmosphere under bell jars at from 17 to 27° failed to germinate, as did all of those placed in water. Those placed on the upper surface of leaves, kept at from 15 to 32° temperature and from 55 to 85 per cent of humidity, showed no germination in 6 days; but spores placed on a watch glass under a bell jar in a very moist atmosphere at from 20 to 35° and watered every 2 to 7 hours germinated in from 2 to 4 days, but after 6 or 7 days no further germination occurred. It is inferred from these tests that the power of germination is retained for about 5 days under conditions favorable to germination, but that it is lost very quickly in a less moist atmosphere, supposedly because of desiccation; that it is the occurrence simultaneously of favorable conditions of temperature and moisture that is to be feared; and that it is at such times that treatment should be employed.

Infection experiments with mildew in Hungary, P. LARUE (*Rev. Vit.*, 37 (1912), No. 954, pp. 416-418).—A résumé of an article already noted (E. S. R., 27, p. 47).

Anatomo-pathological investigations on roncet, A. BIASCO (*Ann. R. Scuola Sup. Agr. Portici*, 2. ser., 9 (1909), Art. 15, pp. 1-9).—A brief account is given of the anatomical alterations marking the progress of this disease.

The Panama disease of bananas (*Agr. News [Barbados]*, 11 (1912), Nos. 260, pp. 126, 127; 261, pp. 142, 143).—This gives a summary of knowledge relating to some of the diseases of the banana and particularly that known as the Panama disease.

It is thought that there are probably two distinct diseases which affect the vascular bundles, and therefore the water supply, of certain varieties of plantains and bananas. The first is the Moko disease, which is attributed to *Bacillus musa*, while the second is designated as the Surinam Panama disease, caused by *Leptospora musa*. In addition it is stated that possibly the Panama disease of Central America is distinct from the above.

Diseases of vanilla. C. MAUBLANC (*Agr. Prat. Pays Chauds.* 12 (1912), Nos. 108, pp. 177-188, figs. 2; 109, pp. 277-287, figs. 4).—The author describes a number of fungus diseases of vanilla, among them anthracnose due to *Colospora vanilla*, brown spotting of the stems caused by *Nectria vanillæ*, rust caused by *Uredo scabies*, leaf spots caused by *Fusicladium vanillæ*, *Phyllosticta vanillæ*, *Amerosporium vanillæ*, and *Ocellaria vanillæ*, and attacks by *Scutelia coffeicola*, *S. vanillæ*, and *Cephaluros henningsii*.

Notes upon tree diseases in the eastern States. P. SPAULDING (*Mycologia*, 4 (1912), No. 3, pp. 148-151; *abs. in Phytopathology*, 2 (1912), No. 2, p. 93).—The author describes a number of diseases of forest trees in the eastern United States. Notes are given on the distribution of the chestnut blight to the North, South, and West.

A serious disease of balsam fir, caused by *Lophodermium nervisquum*, is noted as occurring in the Adirondack region. It causes the death of much young growth. Infection occurs in June, the fruiting bodies being formed on the same needles about a year later.

An apparently serious disease of maple, caused by *Myrosporium acerinum*, is described. The disease is said to be widespread and affects the smaller branches. Cutting out and burning the affected branches seems to be the only practical method of treatment.

A disease of Norway and other spruces, due to *Phoma piccina*, which results in the defoliation and death of trees, is described.

Fungus root rot. W. T. HORNE (*Mo. Bul. Com. Hort. Cal.*, 1 (1912), No. 6, pp. 216-225, figs. 7).—This disease, known also as oak fungus, toadstool disease, etc., and ascribed to the activity of *Armillaria mellea* (other fungi possibly also participating), is said to affect a great variety of trees which are woody and long lived and to be much more abundant than is commonly supposed. It works in areas which tend to enlarge from year to year, revealing its presence by large light brown toadstools beside or around the diseased trees, usually during November and December, and arising from decayed roots of some size deep below the surface of the ground. Immense numbers of spores are produced but these do not seem to spread the disease so actively as do the diseased roots. From their subterranean mycelium often arise shiny black cord-like strands which are able to penetrate the soil for several inches or more and attack healthy roots when reached, thus starting new lines of propagation. The mycelium also spreads upward into a somewhat fan-shaped growth, forming a felty white body within the bark of the trees affected. This white mass crowds directly into the perfectly healthy living portion, with the result that this puffs up and becomes watery and often filled with gummy or gelatinous material. The advance of the mycelium is favored by moisture and tends to cause a very complete white rot of the wood.

It is said to be well to dig and dry the toadstools before they pass beyond the button stage and mature their spores, also to dig and burn or dry the diseased roots, which are almost always of the larger size. The land should then be planted to annual crops not attacked by fungus for a sufficient time to allow the old roots with their mycelium to disappear, or else after a time with trees more or less immune, as pears, black walnuts, figs, cherries, etc. Experiments intending to check the spread along diseased roots, as by nuprooting a zone of sound trees, placing a wall of tarred paper around the infected area, etc., have been attempted with varying expense and success.

The fungus of the chestnut tree blight, W. G. FARLOW (*Science*, n. ser., 35 (1912), No. 906, pp. 717-722).—A discussion is presented relating to the

identity of the fungus which is held to cause the blight of the chestnut tree. The author states that so far as can be distinguished by the morphological characters, *Diaporthe parasitica* as described by Murrill (E. S. R., 19, p. 251) resembles the Italian *Endothia radicalis* so closely that they can not be separated specifically unless it be by some peculiarity not hitherto recorded.

**A twig disease of elms, J. ERIKSSON** (*Mycol. Centrbl.*, 1 (1912), No. 2, pp. 35-42, pl. 1, figs. 3).—The author describes a disease found on *Ulmus montana*, *U. montana cronicensis*, *U. campestris*, and *U. effusa*, which usually attacks the younger shoots and plants, dotting the surface with small black pustules and finally killing the affected parts or plants.

The disease is ascribed to a fungus found in connection therewith. This is claimed to be new and is described under the name *Erosporium ulmi*. Attempts with artificial inoculation were successful in several instances, reproducing the characteristic symptoms of the disease and killing the infected twigs or young plants. As protection against this disease the author recommends careful inspection of nursery stock before purchase and repeated examination of suspected trees with removal and destruction by fire of all dead or visibly infected twigs.

**Fungus enemies of Canada poplar in Santena, P. VOGLINO** (*Ann. R. Accad. Agr. Torino*, 53 (1910), pp. 325-377, figs. 4).—Descriptions are given of 33 species of fungi and bacteria known to infest Canada poplar in Italy.

**Hevea rubber stumps as possible carriers of disease (Agr. News [Barbados], 11 (1912), No. 262, p. 158).**—Attention is called to the statement of Stockdale that imported Para rubber stumps showed the presence of fungi, and a warning given against their indiscriminate introduction. Through the careless importation of rubber stumps it is thought probable that a number of fungi might be introduced, among them *Thyridaria tarda*, *Hymenocharte noria*, *Fomes semitostus*, and *Corticium salmonicolor*.

**Immortel canker, F. W. SOUTH** (*Agr. News [Barbados], 11 (1912), No. 263, p. 174*).—In an account of a recent visit to St. Lucia the author describes a disease of immortal (*Erythrina umbrosa*), which has been known to exist for some time in that island. The disease usually starts from a cut surface, spreads rapidly, and generally kills the tree. In its early stages the bark is somewhat split and covered with a thin, shiny, transparent coating, probably consisting of a dried gummy secretion. Inside the bark is rotted, wet, and of a reddish color. Between the wood and the bark were found numerous insects, which were working almost to the advancing margin of the diseased area. As the disease progresses the parenchyma of the bark is destroyed, and the bark dries and falls off the trees in sheets.

A disease of the same species of *Erythrina* has been reported from Ceylon as due to the same fungus as that causing canker of cacao. This fungus, however, has been determined as *Phytophthora faberi*, a fungus which has not been found to develop from diseased immortal bark in St. Lucia.

It is believed that cutting out and burning the diseased bark, followed by an application of tar, would control the disease.

**Pestalozzia hartigi, a new parasite of the silver fir, T. LAGERBERG** (*Meddel. Stat. Skogsförsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens)*, 1911, No. 8, pp. 95-107, V, VII, figs. 10).—An account is given of a new disease found on young firs in seedbeds and nurseries in Sweden. The plants are first covered with dark or black spots; the lower portions become constricted, and the upper swollen; and the twig or plant finally dies. Cultures were grown and examined, and the disease was attributed to a fungus, *P. hartigi*.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

The vertebrates, O. JAEKEL (*Die Wirbeltiere. Berlin, 1911, pp. VIII+252, figs. 281*).—This work deals with both fossil and living forms.

A pocket list of the birds of eastern Massachusetts with especial reference to Essex County, A. P. MORSE (*Salem, Mass., 1912, pp. 92, tables 6, pl. 1*).—This list includes charts which show the months of the year in which the various species are present in eastern Massachusetts.

The senses of insects, A. H. FOREL (*Das Sinnesleben der Insekten. Munich, 1910, pp. XV+393, pls. 2*).—This is a collection of experimental and critical studies of insect psychology.

Control of insects and diseases in grove, garden, and field, N. M. G. PRANGE (*St. Augustine, Fla., 1912, pp. 156*).—This is a brief popular work.

The destruction of insects and other injurious animals, A. L. CLÉMENT (*Destruction des Insectes et Autres Animaux Nuisibles. Paris [1911], pp. 135, figs. 400*).—This work consists of 5 chapters which take up the subject as follows: (1) The life and anatomy of insects; (2) methods of destruction; (3) insects and other injurious articulates; (4) insects grouped according to the plants which they injure; and (5) injurious animals other than articulates.

Potassium cyanid as a larvicide, S. T. GUNASEKARA (*Brit. Med. Jour., 1912, No. 2678, p. 981*).—In tests of the effect of potassium cyanid on anopheline larvæ the author found 1 part in 75,000 to destroy the larvæ in 12 hours, whereas 1 part in 150,000 had no effect. When used in stagnant pools the results obtained were variable; the highest dilution having any effect was 1 in 50,000 and in some pools as much as 1 in 35,000 was required. A solution of 1 in 37,500, or 8 times the strength recommended, was required for most pools.

Fourth annual report of the state entomologist of Indiana. B. W. DOUGLASS (*Ann. Rpt. State Ent. Ind., 4 (1910-11), pp. 266, figs. 297*).—This report consists of papers on peach growing in Indiana (pp. 13-40); insect enemies and diseases of the peach (pp. 41-66); insects injurious to shade trees, including a list of trees (pp. 67-226); miscellaneous notes on injurious insects (pp. 227-233); and bee keeping (pp. 235-261).

Forty-second annual report of the Entomological Society of Ontario, 1911 (*Ann. Rpt. Ent. Soc. Ontario, 42 (1911), pp. 114, figs. 40*).—Among the more important papers here presented are the following: Reports on Insects of the Year, by A. Gibson (pp. 9-25); Some of the Work of the Division of Entomology in 1911, by C. G. Hewitt (pp. 25-27); Insects of the Season in Ontario, by L. Caesar (pp. 28-36); Notes on the Season of 1911, by T. W. Fyles (pp. 36-38); Some Injurious Forest Insects at De Grassi Point, Lake Simcoe, by E. M. Walker (pp. 55-63); Thrips Affecting Oats, by C. G. Hewitt (pp. 63-65); A Hymenopterous Parasite of *Hepialus thule*, by A. F. Winn (pp. 70, 71); Injurious Insects of the Year, MacDonald College, Quebec, by J. M. Swaine (pp. 72-74); Insect Migration at Aweme, Manitoba, by N. Criddle (pp. 74-76); The Preparation of a Catalogue of the Insects of Canada (pp. 79-81), by C. G. Hewitt; Some Notes on *Hepialus hyperboreus*, by H. Dawson (pp. 81, 82); and Blister Beetles, by A. Gibson (pp. 83-88).

Report of the division of plant protection for the year ended June 30, 1911, C. BRICK (*Jahrb. Hamburg. Wiss. Anst., 28 (1910), pp. 312-337*).—This detailed report of inspection and other work conducted during the year includes a list of the insects, etc., infesting imported plants, the occurrence of insect enemies and diseases of cultivated plants during the year, and an index thereto.

Insect pests of cereals and fruit trees in Russia, I. A. PORCINSKIÏ (*Bzheg. Dept. Zeml. [Russia], 1909, pp. 608, 609; abs. in Internat. Inst. Agr. [Rome],*

*Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 6, p. 1532).—An invasion of *Agrotis* sp. occurred in 1909 in many Governments in Russia, but caused serious loss only in the Governments of Tula and Ryazan. *Diplosis tritici* invaded wheat fields and caused considerable injury in the district of Belev. In eastern Russia serious injury was caused by the invasion of *Hylemyia coarctata*, the larvæ of which destroyed young spring wheat seedlings. *Rynchites pauxillus*, which partially destroyed the foliage of fruit trees, is reported to be spreading in southern Russia.

**Insect pests of fruit trees in Russian Central Asia.** I. A. PORCINSKIÏ (*Ezhgeg. Dept. Zcmf. [Russia]*, 1909, pp. 602-604; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 6, p. 1546).—The codling moth, which was formerly unknown in Central Asia, appears to have been introduced since the opening of the railways with consignments of fruits and plants and has become very destructive in apple orchards throughout Turkestan, where it has no natural enemies to prevent its spread.

Mention is made of the injury by *Tingis pyri* which attacks the pear; *Oxythyrca cinctella*, which attacks the blossoms of fruit trees; and *Colophora alcyonipencilla* and *Agelastica* sp., the latter of which devours the foliage of the walnut and almond.

**Notes on injurious insects observed.** C. W. JEMMETT (*Ann. Rpl. Agr. Dept. [South. Nigeria]*, 1910, pp. 26-30).—These notes deal with the enemies of cotton, corn, maize, cacao, etc.

**Report on economic entomology.** F. P. JEPSON (*Dept. Agr. Fiji Council Paper 25, 1911, pp. V+89, pls. 6*).—This report by the government entomologist deals with the Fijian insect pests as follows: Arthropoda injurious to man and animals; insects, etc., injurious to cultivated crops, including coconut, banana, sugar cane, cacao, pineapple, custard apple, granadillas, yaqona (*Piper methysticum*), cotton, yams, tobacco, melons and pumpkins, and oranges; insects injurious to ornamental shrubs; insects injurious to stored goods; and insects injurious to timber.

The 5 appendixes consist of a glossary of technical terms, directions for the collection of insects, reports on a visit to the Lau group and to Honolulu, and notes on sprays and washes used as insecticides.

**The enemies of the orange and lemon in Spain.** D. L. DE SALAS Y AMAT (*Bol. Agr. Téc. y Econ.*, 4 (1912), Nos. 38, pp. 167-181; 40, pp. 365, 373).—This account deals with the important insect enemies of citrus in Spain, and the remedial measures therefor.

**Mango pests in Cavite and Rizal Provinces.** P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 4 (1911), Nos. 6, pp. 312-314; 12, p. 681).—It is stated that in driving through Imus and adjoining barrios the mango blossoms were observed to be almost universally blackened and dead. By sucking the juices from the buds and tender stems, the homopterous insects *Idiocerus clypealis* and *I. niveosparvus* injure them, causing the flowers to drop. They also secrete a honeydew, in which a sooty mold develops, the presence of the insects being readily detected by the blackened leaves and flower panicles. At Imus, insects had practically ruined the season's mango crop, and they were doing great damage to the mangoes at San Francisco.

Another pest that appears to be quite destructive to the mango bloom is a caterpillar that enters the central stem of the flower panicle and hollows it out, causing it to shrivel and die.

**Insect enemies of poplars and willows.** P. LESNE (*Jour. Agr. Prat., n. ser.*, 23 (1912), No. 14, pp. 433-439, pl. 1, figs. 7).—This is a brief account of some of the more important enemies.

The enemies of *Populus canadensis*, P. VOGLINO (*Ann. R. Accad. Agr. Torino*, 53 (1910), pp. 315-444, figs. 16).—The first part of this paper (pp. 325-377) deals with the vegetable enemies, the second part (pp. 378-440) with the insect enemies, of which 45 species are considered.

The tarbagans and the plague, L. J. TCHAOUSHOV (*Vrach [St. Petersburg]*, 1911, No. 24-25; *abs. in Off. Internat. Hyg. Pub. [Paris]*, *Bul. Mens.*, 3 (1911), No. 9, pp. 1626-1630).—This paper on *Arctomys bobac* deals with its distribution, habits, and diseases, especially in its relation to plague.

Termites and living plants, J. CHAINE (*Compt. Rend. Soc. Biol. [Paris]*, 71 (1911), No. 36, pp. 678-680; 72 (1912), No. 3, pp. 113-115).—These, the sixth and seventh papers (*E. S. R.*, 24, p. 753) on the subject, deal with the protection of plants from termites.

New genera and species of North American Thysanoptera from the South and West, J. D. HOOD (*Proc. Biol. Soc. Wash.*, 25 (1912), pp. 61-75, pl. 1, figs. 6).—The forms here described as new are *Stomatothrips flavus* n. g. and n. sp., from Monterey, Mexico; *Bregmatothrips venustus* n. g. and n. sp., *Haplothrips graminis* n. sp., and *Scopothrips unicolor* n. g. and n. sp., all 3 taken at Brownsville, Tex.; *Rhopalothrips bicolor* n. g. and n. sp., taken on *Opuntia*, near Monterey, Mexico; and *Liothrips varicornis* n. sp., swept from grass and weeds at Monterey, Mexico.

Instructions for the destruction of locusts (*Instrucciones para la Destrucción de la Langosta. Buenos Aires: Govt.*, 1910, pp. 60, figs. 25).—This paper gives detailed information on the destruction of locusts in Argentina.

The hemipterous enemies of cotton in Africa, H. SCHOUTEDEN (*Rev. Zool. Afric. [Brussels]*, 1 (1912), No. 3, pp. 297-321, pls. 2, figs. 12).—The cotton insect pests here considered are the cimicid *Calidea apicalis*, the coreid *Leptoglossus membranaceus*, several species of *Dysdercus*, 4 species of *Oxycarenus*, several plant lice of the genus *Aphis*, and the coccids *Pseudococcus (Dactylopius) perniciosus* and *Chionaspis aspidistree gossypii*.

Recent studies on the spontaneous distribution of phylloxera, B. GRASSI and M. TORI (*Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5, ser., 20 (1911), II, No. 11, pp. 603-611; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Inocl. and Plant Diseases*, 3 (1912), No. 2, p. 574).—The following conclusions have been drawn by the authors:

"It is wholly unlikely that phylloxera can, in compact earth not fissured or mined, affect its spread through the earth without returning to the surface, and thus infecting the roots of other vines. The influence of light on the direction of the path of the new born phylloxera insect is beyond doubt; it is attracted by light as certain moths by the lamp.

"It is likewise beyond doubt, on the other hand, that the new born phylloxera insects can attach themselves and grow without ever having seen the light, taking up their abode on the same root on which they are born (after returning to it, should they happen to have left it). Or they may pass to the other roots of the same or different vines, either in contact with or quite close to the first, traversing the fissures in the soil, the galleries burrowed by animals, the cavities formed by the working of the soil, by decomposition, by putrefaction of organic substances, etc.

"It is not in the like degree certain, but is nevertheless probable, that the new born phylloxera insect reaches the surface whenever attracted there by a little light through the soil; thus the insect obeys the influence of positive phototropism to which it is certainly subject, independently of the quality and quantity of the food it finds available. Probably, once it has reached the surface, the insect does not descend again until after night has set in."

The woolly aphid and the apple in Argentina, J. M. HUERGO (*Bol. Min. Agr. [Buenos Aires]*, 13 (1911), No. 7, pp. 358-401, pl. 1, figs. 22).—A brief account is given of the injury caused by the woolly aphid in Argentina, with directions for combating it.

White fly control, E. W. BERGER (*Fla. Quart. Bul. Agr. Dept.*, 22 (1912), No. 2, pp. 38-113).—This is a summarized account of recent work.

Notes on Cuban white flies with description of two new species, E. A. BACK (*Canad. Ent.*, 44 (1912), No. 5, pp. 145-153, figs. 7).—Nine species are recorded from Cuba, of which *Alcurodicus cardini*, taken from the guava (*Psidium guajava radii*) at Havana and Santiago de las Vegas, and *Aleyrodcs trachoides*, taken from an indigenous solanaceous vine (*Solanum scaphorthianum*) at Santiago de las Vegas, are described as new to science. *A. cardini* is said to become quite abundant on guava at times and when not parasitized becomes the source of injury. In May, 1911, the author received specimens from Cuba, over 90 per cent of which had been parasitized by a hymenopteron.

The other species recorded from Cuba are *Aleyrodcs citri*, *A. nubifera*, *A. howardi*, *A. variabilis*, *A. floridensis*, *A. mori*, and *Paraleyrodcs persca*.

A new coconut pest, D. B. MACKIE (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 3, pp. 142, 143, pl. 1).—The coconut white fly (*Alcurodicus destructor*), first collected in the vicinity of Guinjungan in May, 1911, is said to be confined to a district in Negros Oriental, extending from the barrio of Tabon on the north and the barrio of Zamora on the south, a range of some 35 km. (about 21.7 miles) in length. Most of the coconut groves in this area, which extends from the seacoast back to a range of hills to the west, are infested.

The San José scale, F. LAHILLE (*Bol. Min. Agr. [Buenos Aires]*, 13 (1911), No. 7, pp. 410-416, pls. 2, figs. 2).—A brief general account.

The plum scale (*Lecanium cerasifex*), J. C. CHAPUIS (*Nat. Canad.*, 38 (1912), No. 10, pp. 145-151).—This paper consists of biological notes and directions for combating *L. cerasifex*, which appeared in orchards at Kamouraska, Province of Quebec, in 1911.

Native and foreign parasites of *Diaspis pentagona*, so far known and introduced into Italy. G. MARTELLI (*Abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 6, pp. 1521, 1522).—This is a summary of the work with parasites of the mulberry or West Indian peach scale.

Three common coccid enemies of the orange, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucumán*, 2 (1911), No. 3, pp. 116-133, pl. 1).—Descriptions of the purple scale, Florida red scale, and fern scale, with methods for their control.

Gipsy and brown-tail moth suppression, F. W. RANE (*Ann. Rpt. State Forester Mass.*, 8 (1911), pp. 81-144, pls. 4).—Details of the work of the year with these 2 pests are presented.

A newly invented power truck sprayer from which the tank can be easily removed, and the truck then used the same as any truck, is described. With this sprayer it is possible to spray both sides of the highway at the same time, while traveling.

A brief report of the work of the year with insect parasites by Dr. L. O. Howard is included. The recovery in large numbers of the Japanese egg parasite of the gipsy moth, *Schedius kuvanæ*, was a very encouraging feature of the summer's work. Field observations showed that it had practically become established and that in some localities 30 per cent of the eggs in a given mass had been destroyed by it. The parasite "*Monodontomerus arcus*, which attacks the gipsy and brown-tail moths in the pupal stage, is now to be found practically over the whole of eastern Massachusetts, in several towns near

Providence, R. I., through the southern part of New Hampshire, and into eastern Maine to a point nearly to Bangor. Another species, the *Pteromalus egregius*, referred to in previous reports, and which destroys the brown-tail caterpillars in the winter web, has been found in small numbers over a widely scattered area in Massachusetts, New Hampshire, and Maine. Two other species have greatly increased their range; these are *Apanteles lacteicolor* and *Metcorus versicolor*."

Some very good results are thought to have been obtained in several places from work with the gipsy moth wilt disease, the work with which will be prosecuted on a much larger scale during the following year. More plantings of the brown-tail fungus were made with apparently excellent results. The fungus disease of the gipsy moth is said to still be in the experimental stage. The conditions of the moth work at the present time in cities and towns in the infested district are described.

[Silkworm studies] (*Lab. Études Soie Lyon, Rap. Com. Admin., 14 (1908-1910), pp. XVI+261, pls. 25, figs. 36*).—The sericultural papers here presented include the following: A Study of the Utilization of Cold in Sericulture, by J. Testenoire (pp. 47-54); On a Muscardine of the Silkworm not Caused by *Botrytis bassiana*; A Study of *B. effusa* n. sp., by J. Beauverie (pp. 55-81), previously noted (E. S. R., 26, p. 757); Description of the Habits of *Cricula andrei*, by E. André (pp. 83-89); New and Little Known Saturniids and Pinarids of Senegal, by P. Riel (pp. 91-99); A Study of the Wild Silkworm *Borocera madagascariensis*, by Grangeon (pp. 101-118); The Accustoming of the Silkworm (*Bombyx mori*) to the Leaves of *Scorzonera hispanica*, by C. Villard (pp. 119-122); A Psychid Case Bearing Silkworm (*Enmcta junodi*). (pp. 123-125); and Researches on the Development of the Egg of the Univoltin Silk Moth (pp. 127-152) (E. S. R., 23, p. 759), both by C. Vaney and A. Conte; The External Sexual Characters of Chrysalids (pp. 153, 154), and The Diseases of Silkworms, in which pebrine is dealt with, by D. Levrat and A. Conte (pp. 155-163); A Bostrichid (*Xylothrips flavipes*) Injurious to Silk (pp. 163-167), by A. Conte and D. Levrat; The Genus *Theophila* and the Affinities of *Bombyx mori* (pp. 169-174), and A Classification of the Lepidopterous Silk Producers (pp. 175-256), both by A. Conte.

Potato moths in Bengal in 1911, E. J. WOODHOUSE (*Dept. Agr. Bengal, Quart. Jour., 5 (1912), No. 3, pp. 146-153*).—This is a second report (E. S. R., 25, p. 761).

Notes on the life history of *Nepticula slingerlandella* (Tineidæ), C. R. CROSBY (*Canad. Ent., 44 (1912), No. 1, pp. 25-27*).—The data here presented have been noted from another source (E. S. R., 26, p. 557).

Mosquitoes and river vessels. A. BALFOUR (*Lancet [London], 1912, I, No. 16, pp. 1048-1051, fig. 1*).—The author states that the constant attention which has been given has not prevented the invasion of Khartoum every now and then by mosquitoes (*Stegomyia fasciata*, *Culex fatigans*, etc.) from steamers and boats plying on the Nile. "Not a year passes but that cases of locally acquired malaria are traced, more or less definitely, to infected anophelines brought into the town precincts by river vessels."

Some parasites of *Simulium* larvæ and their effects on the development of the host, E. H. STRICKLAND (*Biol. Bul., 21 (1911), No. 5, pp. 302-338, pls. 5*).—Two parasites, one a worm (*Mermis* sp.) and the other a new sporozoon for which the name *Glugea polymorpha* is proposed, have been found by the author commonly to infest *Simulium* larvæ (*S. hirtipes* and an undescribed species) in streams in the vicinity of Forest Hills, Mass. The *Mermis* does not affect the larval development to any extent, except by slightly increasing its size, but it inhibits the development of the histoblasts to such an extent that

pupation becomes impossible. Parasitized larvæ never pupate, but are killed by the worms when they escape. Of 174 larvæ examined, 41 were found to be parasitized. In one case as many as 12 worms were removed from a single host; they all remained small apparently from insufficient food supply.

Parasitism by *G. polymorpha* was found to vary from 1 to 80 per cent.

On the life history of the ox warble (*Hypoderma bovis*), PETER (*Mitt. Deut. Landw. Gesell.*, 27 (1912), No. 11, pp. 156-163, figs. 6).—In this paper the author reports the results of studies commenced in March, 1910, and continued during the summer of 1911 at Hamburg abattoirs. Illustrations showing the development of the larvæ during the various months of the year are included.

How to get rid of flies, F. P. STOCKBRIDGE (*World's Work*, 23 (1912), No. 6, pp. 692-703, figs. 11).—This paper includes accounts of fly campaigns conducted during 1911 in Weir and Topeka, Kans., Wilmington, N. C., Boston and Worcester, Mass., Baltimore, Md., Washington, D. C., and other cities and towns.

[Transmission of *Trypanosoma hippicum* by the house fly] (*Rpt. Dept. Sanit. Isthmian Canal Com.*, 1912, Apr., p. 41).—"Musca domestica caught in Panama were fed with the blood of guinea pigs richly infected with trypanosomes (*T. hippicum*), and after intervals of 23, 46, and 126 minutes microscopic examinations of fluid from the proboscis of some of the flies were made, and animal inoculations were made with material from others. Actively motile living trypanosomes were demonstrated in the mouth parts of the flies 126 minutes after feeding. . . .

"The fact here experimentally established that *M. domestica* can carry living trypanosomes for so long a time as 2 hours shows that with the naturally acquired disease ample time is given for the transference of the infecting agent from the excoriated patches on the skin of infected mules to the freshly abraded surfaces on the skin of noninfected mules, as was previously assumed from an epidemiological study of the disease and its probable mode of infection."

African fruit flies, F. ZACHER (*Tropenpflanzer*, 16 (1912), No. 5, pp. 236-243, figs. 3).—Eleven species of *Ceratitis* and *Dacus* are known to be of economic importance in Africa.

Fruit fly control, W. M. GIFFARD (*Hawaii. Forester and Agr.*, 9 (1912), No. 4, pp. 108-114).—A brief report of work carried on against the Mediterranean fruit fly in Hawaii.

Systematic notes on North American Tachinidæ, J. D. TOTHILL (*Canad. Ent.*, 44 (1912), No. 1, pp. 1-5).—*Winthemia fumiferanæ* bred from the spruce budworm (*Tortrix fumiferanæ*) in the Provinces of Quebec and British Columbia is described as new to science.

Narcissus fly (*Merodon equestris*) [attacking *Galtonia candicans*], E. H. JENKINS (*Gard. Chron.*, 3. ser., 50 (1911), No. 1296, p. 310).—The author has repeatedly found the larva of *M. equestris* in Dutch cultivated bulbs of *G. candicans*, the earliest instance having been some 22 years ago. In the case of the daffodil, discoloration of the outer tissues of the bulb is a not infrequent indication of the presence of the larva, though it may be as frequently due to the presence of the bulb mite (*Rhizoglyphus* sp.).

Mustard beetles, R. S. MACDOUGALL (*Jour. Bd. Agr. [London]*, 18 (1911), No. 12, pp. 1017-1020, fig. 1).—The insects here considered are the mustard beetle (*Phadon betulæ*) and the turnip, mustard, and cabbage flower beetle (*Meligethes æneus*).

An experimental study on the death feigning of *Belostoma* (= *Zaitha Aucet.*) *flumineum* and *Nepa apiculata*, H. H. P. and H. C. SEVERIN (*Behavior Monographs*, 1 (1911), No. 3, pp. 44, pl. 1; *abs. in Science*, n. ser., 35 (1912), No. 903, pp. 628-630).—The general characteristics of the death feint are dis-

cluded, together with the duration of successive death feints; the effect of dryness and moisture, temperature, and light on the duration; the effect of mutilation; the origin and development of the death feint; and its psychic aspect. A bibliography of 28 titles is appended.

**Dascillus cervinus** as a marshy meadow pest, W. HEROLD (*Centbl. Bakt. [etc.]*, 2. Abt., 33 (1912), No. 17-19, pp. 438-442, pl. 1, figs. 6).—The larva of this beetle is reported to have been the source of injury to meadows in the southern part of the Province of Posen.

**A new enemy of the coconut palm**, G. HERSCHER and L. MILLOT (*Abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 6, pp. 1552-1554).—A small nocturnal beetle of the genus *Hylecoetus*, the larva of which bores in the trunk, is reported to be a serious enemy of the coconut palm all along the northwestern coast of Madagascar.

**A grove of deformed trees**, R. J. TERRY (*Science*, n. ser., 35 (1912), No. 905, p. 715).—A grove of 400 or 500 small persimmon trees in St. Louis County, Mo., is said to have suffered from the ravages of beetles (*Oncideres cingulata*), limbs of young and old trees varying in diameter from 5 to 15 mm. (from 0.2 to 0.6 in.) being girdled and the ends falling to the ground. The girdling is said to be done mainly in September and October.

"There is no tree in the grove that does not present crooked trunk and limbs. The deformities in some cases are extreme. Most of the trees are as a consequence dwarfed, although able to make some advance in growth."

**On an enemy of the coffee tree**, L. DUPONT (*Bul. Écon. Indo-Chine*, n. ser., 14 (1911), No. 90, pp. 392-397, fig. 1).—An account of *Xyleborus coffeæ* and its injury to *Coffea robusta* in Indo-China.

**Bark beetles (Ipidae)** which live in rubber trees, M. HAGEDORN (*Rev. Zool. Afric. [Brussels]*, 1 (1912), No. 3, pp. 336-346, pl. 1, figs. 11).—Twelve species are here dealt with, namely, *Diamerus fici*, *Phloeotribus puncticollis*, *Stephanoderes congonus* n. sp., *S. heveæ* n. sp., *Hypothenemus tuberculosus* n. sp., *Cryptarthrum walkeri*, *Xyleborus affinis*, *X. ambasi* n. sp., *X. camerunus*, *X. cognatus*, *X. confusus*, and *X. spathipennis chausi* n. var.

**A new enemy of the Douglas fir (Pseudotsuga douglasii)**, M. DE KONING (*Abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 6, p. 1554).—The beetle *Strophosomus obsesus* is said to have destroyed the annual shoots of Douglas fir in the Province of North Brabant, Netherlands, young trees being most severely injured. Gradually the dead branches lose their needles and nothing remains but dry wood. Careful observation shows that the bark at their base has been eaten away. As the injured branches live on for some time, the sap which oozes out sometimes forms a thickening just above the wound.

**Apiculture in Tunis** (*Bul. Dir. Gén. Agr. Com. et Colon. Tunis*, 14 (1910), No. 57, pp. 448-475, pls. 2, fig. 1; 15 (1911), Nos. 58, pp. 74-107, pl. 1, fig. 1; 61, pp. 645-700, figs. 6).—A general account of bee keeping in Tunis with statistical data.

**Bee diseases in Ontario**, M. PETTIT (*Ontario Dept. of Agr. Bul.* 197, 1912, pp. 16, figs. 4).—This is an account of American foul brood, European foul brood, and starved or pickled brood, their prevention and treatment. A report of inspection of apiaries of Ontario follows.

**Report on the Isle of Wight bee disease (microsporidiosis)** (*Jour. Bd. Agr. [London]*, 19 (1912), No. 2, Sup. 8, pp. 143, pls. 6, figs. 2).—This report consists of 13 parts, in addition to an extensive bibliography, which take up the subject as follows: Introduction, by G. S. Graham-Smith (pp. 5-11); The History of the Disease (pp. 12-28) and Symptoms (pp. 29-38), by G. W. Bullamore and W. Malden; The Relation of *Nosema apis* to the Isle of Wight Disease, by G. S.

Graham-Smith, H. B. Fantham, and Annie Porter (pp. 39-56); The Life History of *N. apis*, and the Significance of the Various Stages of the Parasite in the Disease, by H. B. Fantham and Annie Porter (pp. 57-78); Experimental Infection with *N. apis*: (a) Earlier Infection Experiments, by H. B. Fantham and Annie Porter (pp. 79-81), and (b) Infection Experiments Carried out During 1911, by G. S. Graham-Smith and G. W. Bullamore (pp. 81-94); The Ways in Which the Disease may be Spread, by G. S. Graham-Smith and G. W. Bullamore (pp. 95-118); Some Field Observations on Natural Methods of Infection, by H. B. Fantham and Annie Porter (pp. 119-122); Examinations of Certain Insects Found in Hives, by H. B. Fantham and Annie Porter (pp. 123, 124); Treatment and Prevention, by G. S. Graham-Smith and G. W. Bullamore (pp. 125-129); Microsporidiosis in Other Hymenoptera: (a) Infection Experiments, by H. B. Fantham and Annie Porter (pp. 130, 131), (b) Observations on Humble Bees, by H. B. Fantham (p. 131), and (c) Infection Experiments and Observations, by G. S. Graham-Smith (pp. 131, 132); Bacteriology of the Disease, by W. Malden (pp. 133-137); and Note on Certain Protozoa Found in Bees, by H. B. Fantham and Annie Porter (p. 138).

A contribution to the embryology and to the biology of *Apanteles glomeratus*, R. GRANDORI (*Redia*, 7 (1911), No. 2, pp. 363-428, pls. 4, fig. 1).—A detailed report of studies of this braconid parasite of the cabbage butterfly (*Pieris brassicæ*).

The pear slug (*Caliroa cerasi* [*Eriocampoides limacina*]), R. L. WEBSTER (*Iowa Sta. Bul.* 130, pp. 167-192, figs. 13).—This is a detailed report of studies of the life history and bionomics and of remedial measures for the pear slug (*C. cerasi*), a brief account of which has been previously noted (E. S. R., 26, p. 863). The subject is taken up under the headings of control measures: past history, destructiveness, and distribution; food plants; classification; life history; and natural enemies. A bibliography of 35 titles is appended.

The slugs feed on the upper surface of the leaves, removing only the upper portion and leaving the veins bare, badly injured trees appearing as if they had been scorched by fire. The damaged leaves dry, turn brown, curl up, and finally fall. Frequently trees are entirely stripped of their foliage in midsummer. Cherry trees, under such conditions, are forced to put out a new growth of leaves, weakening the tree and greatly reducing the crop of fruit the following year.

There appear to be 2 generations of the insect in central and northern Iowa. In central Iowa the first brood slugs appear in June and early in July and the second late in July and during August, the 2 generations generally being quite distinct. The winter is passed by the slugs within their cocoons in the soil. In the spring they pupate, and late in May and early in June the adult sawflies emerge from the cocoons and deposit their eggs under natural conditions just beneath the epidermis of the upper side of the leaves of cherry, plum, and other trees. The egg hatches in from 10 to 18 days and in the vicinity of Ames most of the slugs have become fully grown and have gone into the soil beneath the trees where they are feeding by July 4, the adult flies emerging about the middle of the month. At Ames most of the second brood slugs have disappeared by the middle of September, although a few straggling ones may be found after that time.

Parthenogenesis is thought to occur in this species although it has not been satisfactorily proven. Large numbers of sawflies have been collected and examined by the author without the discovery of a single male. The author has found much variation in the number of molts passed. Thus in 14 cases closely observed 5 larvæ molted 5 times, 5 molted 6 times, 3 molted 7 times, and 1 molted 8 times.

Investigations show hellebore, lead arsenate, and Paris green to be the least expensive of the treatments recommended. One lb. of hellebore to 5 lbs. of air-slaked lime, or 1 lb. of hellebore to a barrel of water; lead arsenate 2 lbs. to 50 gal. of water; Paris green 1 lb. to 150 gal. of water; kerosene emulsion containing 10 per cent kerosene; whale oil soap, 1 lb. to 2 gal. of water; white laundry soap and Ivory soap, one 10-oz. bar to 2 gal. of water were all effective in combating the pest. Attention is called to the fact that cultivation under infested trees is of value since it disturbs the cocoons in the soil.

A sawfly injurious to the gooseberry, G. LÜSTNER (*Möller's Deut. Gärt. Ztg.*, 26 (1911), No. 25, p. 295, figs. 2).—The sawfly *Nematus ventricosus* is reported to have been a serious enemy of the gooseberry in Germany during the early part of the season of 1911.

The large larch sawfly (*Nematus erichsoni*), E. B. DUNLOP (*Zoologist*, 4, ser., 16 (1912), No. 184, pp. 147-156).—A brief account of this sawfly, its habits, injury, etc., in Great Britain.

A contribution to the knowledge of the galls of North America, A. TRÖTTER (*Marcellia*, 10 (1911), Nos. 1, pp. 28-32, pls. 2, figs. 4; 2, pp. 33-61, figs. 17).—Eighty-eight galls collected by F. Silvestri in Oregon, Washington, California, Arizona, Mexico, and Hawaii are here described, many of which are new.

Information concerning ticks (*Agr. News [Barbados]*, 10 (1911), No. 246, p. 314).—A brief account of the occurrence of ticks in the West Indies.

Some new North American Ixodidæ with notes on other species, F. C. BISHOPP (*Proc. Biol. Soc. Wash.*, 24 (1911), pp. 197-208, pl. 1).—Two new species and 2 new varieties are here described, namely, *Ixodes banksi*, taken from muskrat (*Fiber zibethicus*) in Arkansas; *I. kingi*, taken from the badger (*Taxidea taxus*) and other hosts in Wyoming and other western States; *I. cooki rugosus*, taken from the dog in Oregon, Washington, and California; and *I. angustus woodi*, taken from Baird's wood rat (*Neotoma micropus*), in Texas.

New laboulbeniaceous parasites of acarids, G. PAOLI (*Redia*, 7 (1911), No. 2, pp. 283-295, pl. 1).—Three species of Rickia and 3 of Dimeromyces are here described as new.

Handbook of pathogenic protozoa, edited by S. VON PROWAZEK (*Handbuch der Pathogenen Protozoen*, Leipzig, 1912, pt. 3, pp. 249-360, pl. 1, figs. 50).—In this third part (E. S. R., 26, p. 865), the pathogenic trypanosomes are dealt with by M. Mayer (pp. 249-323); the Cnidosporidia (Myxosporidia and Microsporidia), by O. Schröder (pp. 324-344); and the Sarcosporidia, by E. Teichmann (pp. 345-360).

A bibliography accompanies each paper.

## FOODS—HUMAN NUTRITION.

[Refrigeration and food products] (*Ber. II. Internat. Kältkong. Wien*, 1 (1910), pp. 308, pls. 3; 2 (1910), pp. 1085, pls. 2, figs. 67, dgms. 109).—A number of papers were presented at the Second International Refrigeration Congress at Vienna of special interest to students of nutrition and related matters. Volume 2 contains the full papers and volume 1 the discussions, lists of members, and other general data.

Among others the following papers may be mentioned: Changes in the Physical and Morphological Character of Foods (Meat, Fish, and Milk), by Bützler; Cooling Houses and Other Buildings in the Tropics, by J. F. H. Koopman; Studies of the Preservation of Horseflesh by Cold and Its Use for Food Purposes, by A. Costa and N. Mori; The Effect of Low Temperatures on

the Life Processes of Fruits and on the Rate of Fermentation of Cider, by H. C. Gore; The Refrigeration of Poultry and Eggs in the United States, by Mary E. Pennington; The Manufacture of Ice, by Sandras; An Improved Method of Packing Guttled Fish for Transport and Keeping it Fresh and Sweet for a Long Time, by A. Soelling; A New Application of Low Temperature to the Preparation of Concentrated Food Extracts or Solids, Particularly Milk Powder, by F. G. Lecomte and A. R. Loinville; The Preservation of Eggs by Low Temperature, by F. Lescardé; Importation and Exportation of Meat to Different Countries with Special Reference to the Use of Cold Storage and Frozen Meat in the Netherlands, by F. B. Löhnis; The Relative Value of Frozen and Refrigerated Meat for Food Purposes, Particularly with Reference to the Army, the Navy, and Public and Private Institutions, by H. Martel; Refrigeration and Ventilation of Inhabited Places, by H. Torrance, Jr.; Relative Value of Frozen and Refrigerated Meat in General and Particularly for the Army and Large Groups, by H. Viry; Cold Storage and the Preservation of Fresh and Salted Meat, by L. van Wanjenbergh; Feeding the Nations, by A. de Wendrich; and Several Methods of Testing Cold Storage Insulation, with Comparative Results, by W. M. Whitten.

The essential constituents in food, E. F. ARMSTRONG (*Chem. World*, 1 (1912), No. 5, pp. 147-149).—A summary of some of the newer work in nutrition, particularly studies of the effects of cooked and uncooked food and similar topics.

Brooklyn Eagle government cook book (*Brooklyn*, 1912, 2. ed., pp. 112).—This publication is a reprint of Farmers' Bulletins 85, Fish as Food (E. S. R., 10, p. 678); 128, Eggs and Their Uses as Food (E. S. R., 13, p. 166); 142, Principles of Nutrition and Nutritive Value of Food (E. S. R., 13, p. 974); 203, Canned Fruit, Preserves, and Jellies—Household Methods of Preparation (E. S. R., 16, p. 392); 293, Use of Fruit as Food (E. S. R., 19, p. 60); and 391, Economical Use of Meat in the Home (E. S. R., 23, p. 165).

Phosphorus in Indian foodstuffs, D. HOOPER (*Jour. Asiatic Soc. Bengal*, n. ser., 7 (1911), pp. 313-322; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 2, p. 88; *Nature* [London], 88 (1912), No. 2209, p. 594).—The data reported have to do with the phosphorus content of polished and unpolished rice, rice polish, Indian wheat, and wheat flour; and of barley, pearl barley, lentils, cheese, cooked fish, cooked potatoes, beans, pineapple, edible birds nest, and other foodstuffs.

The author discusses the alleged relation of phosphorus in milled rice to beriberi. Experiments made with fowls fed rice of varying quality showed that polyneuritis developed when milled rice was used but not with husked rice. With rice containing only 0.277 per cent phosphoric anhydrid the disease appeared in a few weeks, while with rice containing 0.469 per cent it did not appear. Analyses of rice from various parts of India showed that on an average unmilled rice contained 0.65 per cent phosphoric anhydrid and milled rice 0.38 per cent. Pulses (legumes) contained larger proportions, and, according to the author, it is significant that pulse eaters generally remain free from the disease, while their neighbors, who are rice eaters, are attacked by it.

Cryoscopy of meat extract, T. JONA (*Kryoskopie der Fleischextrakte*. Pavia, 1911, pp. 15; *abs. in Chem. Zentbl.*, 1912, I, No. 14, p. 1136).—Results of cryoscopic studies of meat extracts are reported.

Microbial content of cooked sausage, G. GUÉRIN (*Hyg. Viande et Lait*, 6 (1912), No. 4, pp. 197-207).—Results reported show the occurrence of microorganisms in sausage and on sausage casings.

Analyses of wheats and flours [and barleys], J. C. BRÜNNICH (*Ann. Rpt. Dept. Agr. and Stock* [Queensland], 1910-11, pp. 58-60).—A large number of

analyses are reported. The data for wheat include the yield, weight per bushel, yield of milling products, composition of the flour, results of baking tests, and similar information.

**Technical flour analysis and comparative baking test, O. J. FREED** (*Oper. Miller, 17* (1912), No. 7, pp. 467-469).—The analytical data reported illustrate the methods followed in the technical examination of flour for bread-making purposes.

The effect of organic acids on wheat bread with reference to infection with micro-organisms causing slimy bread, M. P. NEUMANN, K. MOHS, and O. KNISCHEWSKY (*Ztschr. Gesam. Getreidew., 4* (1912), No. 5, pp. 127-132, figs. 3).—The hay bacillus does not develop and cause slimy bread in an acid dough, provided the acidity is equal to at least 0.3 per cent lactic acid or 0.1 acetic acid.

Sour milk can be used in the baking industry as a convenient method for hindering slimy bread. Organic acids exercise a favorable effect upon the character of the bread, since they increase volume and improve the porous texture. Lactic acid proved the most satisfactory, about 0.5 per cent being the maximum amount desirable. With over 1 per cent the expansion of the dough was not nearly so good. With acetic acid the quantities are somewhat smaller, 0.3 per cent being the maximum amount which can be used without affecting the dough unfavorably. Formic acid, owing to the small quantities in the dough, is without special effect upon the fermentation. According to the investigations reported, 0.2 per cent prevents the development of the micro-organisms causing slimy bread.

Some experiments on the relative digestibility of white and whole meal breads, L. F. NEWMAN, G. W. ROBINSON, E. T. HALNAN, and H. A. D. NEVILLE (*Jour. Hyg. [Cambridge], 12* (1912), No. 2, pp. 119-143).—The chief purpose of the experiments reported was to study the relative digestibility of white and so-called "standard" breads. The tests were made with 4 men and were of 7 days' duration.

"With regard to digestibility, the information given by the experiments may be looked upon as conclusive. The 4 individuals who ate the breads varied greatly in physical type, and the 2 forms of bread were eaten by all under strictly comparable conditions.

"As measured by energy and protein the degree of absorption in different individuals showed marked uniformity. In the case of phosphorus 1 individual showed a degree of absorption which was considerably less than that of the other subjects. The results as a whole lend no support to any extreme view as to the advantages or disadvantages possessed by standard bread: at any rate as regards the availability of the main and more familiar food constituents.

"With respect to the availability of their total energy white bread and standard bread differ but little. With regard to protein there is a distinct advantage on the side of white bread, some 3½ per cent more of its nitrogen-content being absorbed.

"On the other hand, the experiments lend no support to the belief that the phosphorus compounds of bread of the "standard" type are worse absorbed than those of white bread, so that the former contains an appreciably larger amount, not only of total, but of available phosphorus. The ratio of available phosphorus to available nitrogen stands, in the case of the standard bread, nearer to the ratio present in efficient mixed dietaries, a circumstance, however, which only becomes of practical significance when bread forms a large proportion of a person's dietary."

Experiments for a shorter period (3 days) were made with 2 of the subjects with 2 breads containing a larger proportion of the wheat berry than so-called

"standard" breads, the results showing that the availability of the nitrogen and phosphorus present was lower. "With regard to the possible importance and special nutritive influence of unknown constituents present in the cortex of wheat, the experiments described yield no evidence. The periods were of course much too short, and, moreover, to judge from the available knowledge on the matter, the milk taken would supply an equivalent for such factors. They can only be of practical importance in cases where bread forms a very large proportion of the total dietary, and their influence can only be tested by long observations carried out on special communities."

**Principles of jelly making**, NELLIE E. GOLDTHWAITE (*Cornell Reading Courses, Food Ser., 1912, No. 3, pp. 241-254*).—Results of the author's experiments (E. S. R., 24, p. 363) are summarized with particular reference to home jelly making.

**Studies of the utilization of dum palm: The chemical composition and food value of its fruit** (*Agr. Colon. [Italy], 6 (1912), No. 4, pp. 129-152*).—Analyses are reported and discussed.

[**Mince-meat and other pure food and drug topics**], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul., 2 (1912), No. 5, pp. 81-92, 94-96*).—Results are reported and discussed, of the examination of 51 samples of mince-meat and of miscellaneous foodstuffs.

Of the samples of mince-meat examined, 19 contained no meat or less than 1 per cent (i. e., no meat fiber could be detected), 18 contained less than 3 to 6 per cent meat, and 14 less than 6 to 10 per cent. In cases of samples containing no meat fiber, "the flavor of meat was undoubtedly due to the presence of meat extract."

Seven of the samples contained glucose. Commenting on the results of their investigations, the authors state that "to add starch or glucose, making the same largely a constituent of the [mince] meat, is equally deceptive. The fruit can not legitimately be tomatoes, or apple skins, or waste material generally discarded as articles of food."

According to the authors' view, few of the preparations examined were entitled to be classed as mince-meats under ordinary definitions.

**Vinegar and vinegar laws**, J. O. JORDAN (*Mo. Bul. Health Dept. Boston, 1 (1912), No. 3, pp. 57-59*).—A proposed law regulating the sale of vinegar is outlined.

**Official food analysis, 1912**, R. E. ROSE and A. M. HENRY (*Fla. Quart. Bul. Agr. Dept., 22 (1912), No. 2, pp. 194-197*).—Analyses of miscellaneous food materials are reported.

[**Food inspection and other pure food topics**] (*Tenn. Food and Drugs Insp. Bul. 5, 1911, pp. 100, fig. 1*).—Results of the examination of a number of miscellaneous foods are reported, and short weights, pure food and drugs, and related topics are discussed.

**Camp cookery in the West**, C. F. SAUNDERS (*Country Life Amer., 22 (1912), No. 3, pp. 51, 52, figs. 6*).—Camp provisions, methods of camp cookery, and other similar problems are discussed and some recipes given.

**Cooking with electricity**, ELLEN A. HUNTINGTON (*Deseret Farmer, 7 (1912), No. 37, pp. 792, 793*).—Electrical cooking apparatus is discussed, particularly with reference to its cost.

[**Report of the**] committee on markets, AMY A. BRADLEY (*Women's Municipal League Boston Bul., 3 (1912), No. 5, pp. 24-26*).—An account is given of the survey work with reference to market conditions in Boston and the attempts which have been made to remedy them.

**The budget of a vine dresser's family in Caltagirone**, C. CONIGLIO (*Rivista [Conegliano], 5. ser., 18 (1912), Nos. 8, pp. 177-181; 9, pp. 201-206; 10, pp.*

232-235).—Data regarding the amount and cost of individual foods, as well as total expenditures for food, are summarized in this statistical study of the household expenditures of an Italian vineyard laborer's family.

Synthesis of cell building material in plants and animals, E. ABDERHALDEN (*Synthese der Zellbausteine in Pflanze und Tier*. Berlin, 1912, pp. X+128).—The author discusses fundamental problems of nutrition on the basis of his own extended investigations and the work of others.

Such questions are considered as the work of plant cells, the synthesis of cell building material by plants; the work of animal cells; the transformation of nutritive material in the body substances, blood, and cell substances; the metabolism of carbohydrates, fats, phosphatids, nucleo-proteids, proteids, and inorganic material in organic combination; the solution of the problem of nutrition with synthetic products (E. S. R., 26, p. 869); and the possible application of recent work along such lines to invalid dietetics.

Experiments on the influence of a number of foods upon the solubility of uric acid, M. HINDHEDE (*Skand. Arch. Physiol.*, 27 (1912), No. 1-3, pp. 87-99, figs. 3).—Continuing experiments previously reported (E. S. R., 26, p. 765), the author studied the effects of different foods upon the solubility of uric acid and the presence in the urine of uric acid which precipitates. In general, he concludes that a bread, potato, and fruit diet, with small amounts of milk, is the ideal in this respect, as distinguished from the sort of vegetarian diet made up chiefly of such foods as beans, peas, lentils, cabbage, salad plants, and spinach.

The influence of an excess of sodium chlorid upon nutrition and renal excretion, A. DESGREZ and Mlle. B. GUENDE (*Compt. Rend. Acad. Sci. [Paris]*, 154 (1912), No. 15, pp. 939-941).—According to the results of experiments with dogs which are briefly reported, an excess of sodium chlorid without an excess of water lowered the metabolism of nitrogen qualitatively and quantitatively. When the excess of salt was accompanied by an excess of water the excretion of nitrogen was increased quantitatively but lowered qualitatively. In all cases an excess of sodium chlorid apparently diminished cleavage processes qualitatively. It would seem that salt in excess, lowering, as it does, elaboration and elimination, would favor autointoxication.

The elimination of caffein: An experimental study of Herbivora and Carnivora, W. SALANT and J. B. RIEGER (*U. S. Dept. Agr., Bur. Chem. Bul.* 157, pp. 23).—According to the authors' investigations, continuing previous work (E. S. R., 27, p. 166) caffein introduced subcutaneously, by mouth, or intravenously, is eliminated by rabbits and guinea pigs in part unchanged, in the urine, into the gastrointestinal canal, and into the bile. The amount recovered in the urine was in most cases approximately from 6 to 10 per cent with rabbits and from 6 to 11 per cent with guinea pigs. More caffein was eliminated in the urine on a diet of carrots than of oats and hay, but the reverse was noted with the elimination into the gastrointestinal tract, which was marked with both kinds of animals.

"The presence of very small quantities of caffein in the gastrointestinal contents of animals at the end of 48 hours points to its reabsorption into the circulation, since destruction of caffein is highly improbable on account of its resistance to bacterial action."

Cats and dogs were found to eliminate very small quantities, slightly over 1 per cent of the amount ingested. "The elimination of caffein begins soon after its introduction into the circulation. It was found in the urine from 15 to 40 minutes after its subcutaneous injection and in some cases continued to be present for 48 hours. The greater part, however, is eliminated during the first 24 hours, only small quantities being found in the urine later.

"The data herein presented lead to the conclusion that in the carnivora larger amounts of caffeine are demethylated than in the herbivora, and that the resistance to caffeine is inversely as demethylation, since it has been shown that caffeine is much more toxic for carnivora than herbivora. The mechanism of demethylation is in all probability utilized in the body as a means of defense against the deleterious action of caffeine, being more active in organisms for which the drug is more toxic."

A bibliography is appended.

Studies on water drinking.—XIII. Hydrogen ion concentration of feces. P. E. HOWE and P. B. HAWK (*Jour. Biol. Chem.*, 11 (1912), No. 2, pp. 129-140).—The hydrogen concentration of the feces of 2 men was determined in a water drinking experiment, and of 1 man in a fasting experiment, with the usual preliminary and final periods.

"The reaction of the feces was uniformly alkaline, the hydrogen ion concentration varying between  $0.15 \times 10^{-8}$  and  $9.8 \times 10^{-8}$ . As the result of water drinking with meals there was a tendency for the hydrogen ion concentration to increase. Pronounced changes in the dietary régime, such as high protein, low protein and fasting, did not affect the hydrogen ion concentration of the feces sufficiently to cause other than small variations in the uniformly alkaline reaction. As the result of fasting, the stools were alkaline in reaction (hydrogen ion concentration of  $1.4 \times 10^{-8}$  and  $0.94 \times 10^{-8}$ ) as opposed to the acid stools reported by previous investigators. The hydrogen ion concentration differs for the feces of different individuals living on the same diet."

Earlier work has been previously noted (E. S. R., 27, p. 168).

Fasting studies.—VI. Distribution of nitrogen during a fast of one hundred and seventeen days, P. E. HOWE, H. A. MATILL, and P. B. HAWK (*Jour. Biol. Chem.*, 11 (1912), No. 2, pp. 103-127, fig. 1).—In general, the percentage of nitrogen distribution was similar to that reported by the authors in connection with shorter fasting studies with dogs (E. S. R., 26, p. 360).

Fasting studies.—VII. The putrefaction processes in the intestine of a man during fasting and during subsequent periods of low and high protein ingestion, C. P. SHERWIN and P. B. HAWK (*Jour. Biol. Chem.*, 11 (1912), No. 3, pp. 169-177).—Continuing the above experiments, the present investigation was conducted with a normal man weighing 76 kg. to study the influence of fasting, and a subsequent feeding of low and high protein diets upon the course of intestinal putrefaction. The authors summarize the work as follows:

"Intestinal putrefaction as measured by the output of urinary indican was markedly decreased during the fasting interval. The seventh fasting day showed an indican excretion amounting to 13.7 mg. as against an output of 60.5 mg. for the second fasting day. During the postfasting interval of low protein ingestion putrefaction was increased in a very pronounced manner, the indican values rising far above those obtained during the normal period preceding the fast. The average daily indican output was but slightly higher during the period of high protein ingestion than during the low period.

"The indican data for the preliminary period, when taken into consideration in connection with other similar data collected previous to certain tests upon the influence of a high water ingestion, furnish an important verification of a conclusion previously reported from this laboratory to the effect that 'the drinking of copious or moderate volumes of water with meals decreases intestinal putrefaction as measured by the urinary indican output.'

"It was demonstrated that intestinal putrefaction was 50 per cent greater when but 5.23 gm. of nitrogen was passed into the gastro-intestinal tract after the fast than it was when 21.86 gm. of nitrogen was ingested before the fast.

"Data from this and previous experiments along similar lines made upon [one of the subjects] seem to indicate that there is of necessity no uniform relationship between the urinary indican excretion and the output of bacteria in the feces, even when the diet of the subject is of the same general character.

"The indican value for the high protein period subsequent to the fast was approximately 60 per cent higher than the indican value for the preliminary period, notwithstanding the fact that the ingested diet was identical in kind and quantity in the two instances.

"On the seventh day of fasting approximately 40 per cent of the total quantity of ethereal-SO<sub>2</sub> excreted in the urine was in the form of indican-SO<sub>2</sub>, whereas only about 10 per cent was excreted in this form in the urine of the fourth fasting day."

**An experiment on a fasting man, F. G. BENEDICT** (*Science, n. ser., 35 (1912), No. 909, p. 865*).—A brief note is given regarding a 31-day experiment during complete fasting. Many factors, including those measurable with the respiration calorimeter, were taken into account.

**The interstitial granules of striated muscle and their relation to nutrition, E. T. BELL** (*Internat. Monatschr. Anat. u. Physiol., 28 (1911), No. 10-12, pp. 297-347, pl. 1; abs. in Zentbl. Biochem. u. Biophys., 13 (1912), No. 3, p. 92*).—The interstitial granules of striated muscles of mammals were found to consist chiefly of liposomes. Neither fatty acids nor soaps were found.

During fasting the liposomes disappear from the muscle and appear again on feeding. In the case of the frog an increase of these bodies is noticed at the beginning of summer and a decrease in autumn. When rats are fed fat meat a marked increase in liposomes is noted and a deepening of their color. The author believes that the liposomes are not cellular organs but fat depositories.

An extended bibliography is included.

**Idiosyncrasy and anaphylaxis (Med. Rev. of Reviews, 18 (1912), No. 6, pp. 366, 367)**.—The data here summarized indicate that idiosyncrasies observed in individuals with respect to different articles of diet may be attributable to hyper-susceptibility to the toxic action of proteids or other material.

**The respiration calorimeter and its uses for the study of problems of vegetable physiology, C. F. LANGWORTHY and R. D. MILNER** (*Jour. Biol. Chem. 11 (1912), No. 2, Proc., p. xxxiii*).—A brief account is given of the use of the respiration calorimeter (E. S. R., 25, p. 570) for the study of problems concerned with ripening fruit and of the construction of a new calorimeter specially designed for use in the study of such problems.

**Nutrition laboratory, F. G. BENEDICT** (*Carnegie Inst. Washington Year Book, 10 (1911), pp. 183-197*).—A brief description is given of the equipment, investigations in progress, publications, and work of the laboratory in general.

## ANIMAL PRODUCTION.

**The influence of selection and assortative mating on the ancestral and fraternal correlations of a Mendelian population, E. C. SNOW** (*Proc. Roy. Soc. [London], Ser. B, 85 (1912), No. B 578, pp. 195, 196*).—"In general terms, it was established that the effect of taking a selected sample instead of a random one from a population showing a zero coefficient of assortative mating would be to find the ancestral and fraternal correlations within that sample less than those of a random sample, so long as the variability was diminished by the selection. If an ancestor be selected, the correlations between that ancestor and descendants diminish in geometrical progression. On the whole, selection of parents appears to affect the correlations between them and their offspring to a greater extent than it affects the relationship between those offspring them-

selves. For all ancestral cases the regressions appear to be more stable properties of a particular population than the corresponding correlations; frequently the regression of offspring on ancestor is the same as for a random sample, though the correlation is changed. . . .

"The value 0.5 in each case for the fraternal and parental correlations obtained when random samples of a general Mendelian population are dealt with does not depend upon the fact that the samples are random ones, but upon the fact that for such a population the frequency of the heterozygote is twice the geometric mean of the frequencies of the dominant and recedent homozygotes. For, if any selected sample of the form  $p^2(AA) + 2pq(Aa) + q^2(aa)$  be taken from the general population  $p^2(AA) + 2pq(Aa) + q^2(aa)$ , the parental and fraternal correlations reached when the individuals of the selected sample mate at random within the sample always have the constant value 0.5. . . .

"Assortative mating within a random sample of the general population, if positive, increases the parental and sibling regressions as well as the correlations. The ancestral regressions diminish in geometrical progression, the correlations not perfectly, but nearly so. In certain cases the expressions found for the parental and sibling correlations were identical with those reached by the very general methods previously employed by Pearson, and which have no connection whatever with Mendelism, but this can hardly be more than a curious coincidence.

"[In] assortative mating within a selected sample, the regression of offspring on parent depends upon both the assortative mating and the intensity of selection, and increases as those factors increase. Selection and assortative mating affect the correlations in opposite directions, the decreasing tendency of the former appearing to have the predominating effect in practical cases. The sibling correlation is not raised so much by assortative mating nor reduced so much by selection as is the parental one.

"Fairly similar qualitative results were found throughout for somatic characters, though not so much weight can be given to them as to those for gametic characters. Moreover, it is the latter which agree most closely with observation. It is to the results for gametic characters, therefore, that we must look for theoretical verification for experimental conclusions which, at first sight, appear paradoxical, e. g., the closeness of the resemblance between cousins."

See also a previous article (E. S. R., 27, p. 175).

**Mendel's principles of heredity.** A. H. MARSH (*Jour. East Africa and Uganda Nat. Hist. Soc.*, 2 (1911), No. 3, pp. 52-60, pls. 2).—A popular exposition of Mendel's law, with special reference to applying it to the improvement of domesticated animals in East Africa.

**Concerning the inheritance and the origin of species,** J. GROSS (*Biol. Centbl.*, 31 (1911), Nos. 6, pp. 161-177; 7, pp. 193-214; *abs. in Zentbl. Allg. u. Expt. Biol.*, 2 (1912), No. 24, pp. 641, 642).—A criticism of the extreme views of the Mendelians.

**On the changes in the cranial capacity caused by domestication,** B. KLATT (*Sitzber. Gesell. Naturf. Freunde Berlin*, 1912, No. 3, pp. 153-179, figs. 9).—Measurements of skulls of wild and domesticated animals are given, with a discussion of the changes that have taken place. The cranial capacity of domesticated sheep, swine, and dogs was found to be smaller than that of closely related wild species.

**The inheritance of the dun coat color in horses,** J. WILSON (*Sci. Proc. Roy. Dublin Soc., n. ser.*, 13 (1912), No. 14, pp. 183-201).—Additional data (E. S. R., 23, p. 476) are cited as a further illustration that dun is recessive to gray and roan, and dominant to brown, bay, black, and chestnut.

The nature of the inheritance of horns in sheep, T. R. ARKELL and C. B. DAVENPORT (*Science, n. ser.*, 35 (1912), No. 911, p. 927).—An explanatory note concerning the work of Castle previously noted (*E. S. R.*, 27, p. 370).

Is there association between the yellow and agouti factors in mice? A. H. STURTEVANT (*Amer. Nat.*, 46 (1912), No. 546, pp. 368-371).—Evidence is submitted to show that the ticking or the agouti factor is closely associated with the factor which produces yellow-haired mice.

Evidence of the zebra in the pleistocene fauna of France, S. TROTTER (*Science, n. ser.*, 33 (1911), No. 849, p. 530).—A study of the drawings in *L'Art pendant L'Age du Renne*, by Edouard Piette (Paris, 1907), leads the author to believe that the zebra lived in western Europe as a contemporary of the cave bear, woolly rhinoceros, and other animals depicted by paleolithic man.

Some current conceptions of the germ plasm, R. A. HARPER (*Science, n. ser.*, 35 (1912), No. 911, pp. 909-923).—This is an address made before the American Association for the Advancement of Science, 1911, and in which the recent studies on fundamental problems of cell behavior and heredity are reviewed. The author finds that the later researches strengthen the view that chromosomes are the bearers of hereditary traits, but that the attempt to express the results in terms of unit characters is but a relic of the earlier corpuscular and preformational theories of heredity.

On melanin, R. A. GORTNER (*Biochem. Bul.*, 1 (1911), No. 2, pp. 207-215).—A summary of work, wherein it is pointed out that the work of different investigators is not comparable because of the diversity of methods. The following conclusions are drawn:

"All available data indicate that the formation of melanin is brought about by the interaction of an oxidase and an oxidizable chromogen. Melanins are of at least 2 types, which may be differentiated by their solubility or insolubility in dilute acids. Those melanins which are soluble in dilute acids are of a protein nature, and for this type the name melano-protein is suggested. It appears probable that these melano-proteins are not present as granules, but that they are 'dissolved' in the keratin structure. The melanins which are insoluble in dilute acids are of an unknown constitution, and are, probably, the 'pigment granules' which may be seen in the hair and tissues. It is probable that they are formed by the oxidation of a different chromogen from that which yields the melano-proteins. The protein portion of the melano-protein molecule is readily decomposed by the action of alkalis or acids, and colored products are obtained which are not soluble in dilute acids. Tyrosin, lysin, and arginin have been identified among the hydrolytic products of a melano-protein. Sodium hydroxid solution decomposes the melanin molecule, and causes a loss of both nitrogen and hydrogen. As many different products as may be desired can be obtained by varying the strength of the alkali employed."

The origin of the melanotic pigment in the embryonic eye and in malignant tumors, A. VON SZILLY (*Arch. Mikros. Anat.*, 77 (1911), No. 2, I, pp. 87-156, pls. 4; *abs. in Jour. Roy. Micros. Soc.* [London], 1912, No. 2, pp. 168, 169).—The author studied the eyes of several vertebrate embryos and melanotic tumors in the eye of man. The pigment bearers were found to arise from the chromatin of the nucleus and pass into the cytoplasm, being comparable to chromatidia. Some are of a degenerative type, and their appearance is associated with a partial breakdown of the nucleus. The change of colorless pigment bearers into pigment is brought about by specific cell ferments, which act on the chromatin.

On melanin of animal origin, M. PIETTRE (*Compt. Rend. Acad. Sci.* [Paris], 153 (1911), No. 17, pp. 782-785; *abs. in Chem. Ztg.*, 35 (1911), No. 144, p.

1335).—From the sarcomatous tumors in horses the author isolated by acid hydrolysis a protein fraction and a more condensed jet-black nucleus insoluble in acids but easily soluble in alkalis.

**American Society of Animal Nutrition** (*Amer. Soc. Anim. Nutrition Proc.* 1911, pp. 37).—This contains the minutes of the annual meeting held in November, 1911 (E. S. R., 26, p. 197), including the president's annual address on Some Unsolved Problems, by H. P. Armsby (pp. 4-12), and the following papers: Methods in Nutrition Investigation, by E. B. Forbes (pp. 12-21); The Feeding Experiment: Its Improvement and Refinement, by H. J. Waters (pp. 21-28); and Animal Nutrition Investigations in the Bureau of Animal Industry, by G. M. Rommel (pp. 28-30).

**Analyses of fodder plants, grasses, and root crops**, J. C. BRÜNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1909-10*, pp. 58-60).—Analyses are reported of Early Amber cane, *Sorghum saccharatum*, white and red Kafir corn, *Andropogon ipermedius*, *A. affinis*, *Anthistiria arcuata*, *A. ciliata*, *Panicum bulbosum*, spring grass (*Eriochloa punctata*), *Trysacum dactyloides*, *Erodium cygnorum*, *Atriplex halimoides*, *Medicago sativa*, *Lotus australis*, oat chaff, oil cake, imphee silage, cowpea and sorghum silage, turnips, kohlrabi, swedes, mangolds, carrots, sugar beets, and kangaroo grass.

[Analyses of feeding stuffs], H. H. MANN (*Ann. Rpt. Dept. Agr. Bombay, 1910-11*, p. 62).—Analyses of several new fodders are reported, which include the following: Babul pods, water 5.5, ether extract 2.2, protein 11.63, soluble carbohydrates and tannin 59.3, fiber 16.47, and ash 4.9 per cent; and rice konda, water 8.23, ether extract 8.54, protein 32.89, soluble carbohydrates 37.72, fiber 4.9, and ash 7.72 per cent.

The rice konda consisted chiefly of the inner husk and germ obtained in grinding rice. It is thought that babul would form a nutritious fodder, except those varieties containing so large an amount of tannin that they are not relished by stock.

**Inspection and analyses of commercial feeding stuffs on sale in the State**, W. F. HAND ET AL. (*Mississippi Sta. Buls.* 153, pp. 31; 154, pp. 39).—Analyses are reported of wheat shorts, bran and middlings, corn chop, hominy feed, rice polish, rice bran, molasses feeds, and mixed feeds.

**Concentrated commercial feeding stuffs**, A. L. GARRISON (*Tenn. Agr.*, 1 (1912), No. 2, pp. 35-73).—Analyses are reported of alfalfa meal, wheat bran and shorts, linseed meal, cotton-seed meal, and proprietary mixed feeds.

**Molasses and molasses feeds**.—Composition and feed values of rice by-products, J. E. HALLIGAN (*Baton Rouge: La. Bd. Agr. and Immigr.*, [1912], pp. 20, fig. 1).—This is a popular discussion of the feeding value of molasses and rice by-products. Samples of rations for different farm animals are given.

**Animal breeding**, G. WILSDORF (*Tierzüchtung. Leipzig, 1912*, pp. 110, pls. 12).—This is a brief popular treatise on the feeding, breeding, and management of all kinds of live stock.

**Cattle in Latin America**, P. BERGÉS (*Trab. 4. Cong. Cient. Santiago de Chile, 15 (1908-9)*, pp. 508-512, pls. 2).—This contains live stock statistics of the Latin American countries.

**The live-stock industry in the Department of Junin**, A. L. GARCÍA (*Bol. Dir. Fomento [Peru]*, 9 (1911), No. 5, pp. 1-44).—It is stated that this region is better adapted to sheep raising than to cattle raising. Data are given as to the amount of wool exported from Peru to different countries from 1903 to 1909, and the amount, value, and origin of imports of condensed milk, butter, and cheese during the years 1904 to 1909.

**The meat industry of Argentina**, J. E. RICHELET (*An. Soc. Rural Argentina, 46 (1912), No. 2, pp. 160-201, figs. 28*).—A general and statistical article.

Official enumeration of cattle in the Canton of Bern (*Mitt. Bern. Statist. Bur.*, 1911, No. 3, pp. 92).—This gives in detail the statistics of all kinds of live stock in Bern.

Live stock and products thereof (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1909-10, pp. 15-19, 135-148).—This contains general and statistical information on the live-stock industry in Queensland.

[Defrosting beef and mutton] (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 3, p. 239).—A brief description of a process by which frozen meat is thawed in a chamber so constructed that the atmospheric pressure can be regulated and excess moisture extracted without breaking the tissues of the meat. It is claimed that beef and mutton thus treated compare favorably in appearance when placed on the market with prime English meat.

[British meat supplies], J. L. GRIFFITHS (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 121, pp. 722, 723).—This contains statistics on imports of beef, mutton, and pork from different countries, showing how the decrease in imports of meat from the United States to Great Britain has been replaced by shipments from Argentina.

An industry that thrives on the utilization of waste. E. SCHERUBEL (*Sci. Amer.*, 106 (1912), No. 24, pp. 538, 549-552, figs. 6).—A popular account of the use made of the by-products of the packing house.

Hides and sheepskins. E. J. SHELTON (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 4, pp. 297-306, pls. 3, fig. 1).—This contains advice on skinning, curing, and marketing hides.

Sheep raising in southern Chile (*Times [London]*, 1911, June 27, *So. Amer. Sup.* No. 12, p. 34; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 8-10, p. 2200).—A general and statistical account of the rapidly growing sheep industry in the southern part of Chile, which until recently was regarded as a desert.

Sheep and wool for the farmers. J. W. MATHEWS (*Agr. Gaz. N. S. Wales*, 23 (1912), No. 3, pp. 185-207).—Besides a general discussion of the cross-bred *v.* the Merino, there is an account of the results obtained thus far at the Wagga experimental farm.

The pastoral age in Australasia. J. COLLIER (*London and Melbourne*, 1911, pp. XI+345, pls. 16).—A popular history of the sheep industry in Australia.

The economic importance of the South American Camelidæ. D. DAVEL (*Trab. 4. Cong. Cient. Santiago de Chile*, 15 (1908-9), pp. 234-240).—This discusses the value of the llama, alpaca, vicuña, and guanaco as domesticated animals.

Profitable pig breeding and feeding. T. ALLEN (*London*, 1910, pp. XI+196, pls. 9, figs. 24).—A practical treatise on the feeding, breeding, and management of swine, written for the purpose of promoting the industry in Great Britain.

Fattening hogs in Nebraska. W. P. SNYDER (*Nebraska Sta. Bul.* 124, pp. 5-71).—The material in this bulletin has been previously noted (*E. S. R.*, 26, p. S74), additional technical details being here given.

Slaughter trials with swine. N. O. HOFMAN-BANG ET AL. (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsög [Copenhagen]*, 77 (1912), pp. 35).—Transportation trials with pork were made in a refrigerator car and in a common freight car, with hay or sawdust mattresses 3 in. thick laid on the floor and placed around the walls of the car. The air temperature at the time of loading was 19.5° C. The temperature of the pork in the refrigerator car was 8.3° at loading and at the end of the journey. The average temperature of the pork when placed in the common freight car was 8.7°, and at the end of the 40-hour journey it had risen to 12.3°. For this limited period it is, therefore,

concluded that it is practical to ship pork in freight cars in the manner indicated.

Experiments are also reported with different methods of piling pork during the salting process, and with salting hard and soft pork. The latter trials show that soft pork takes up more brine by injection than hard pork, but during the salting process the soft pork shrinks more, so that there will be from  $\frac{1}{2}$  to over 2 per cent more salted hard than soft pork.

**Pig clubs in England and Wales in 1910** (*Jour. Bd. Agr. [London], 19 (1912), No. 3, pp. 203-209*).—This contains data on the cooperative societies for insuring pigs. There are over 1,000 of these in England and Wales, 32 of which are registered.

**Kemerton and Overbury pig club** (*Jour. Bd. Agr. [London], 19 (1912), No. 3, pp. 209-214*).—Statistics are given of a cooperative society for insuring pigs which has been in operation for 25 years.

**The feeding of the horse**, E. LAVALARD (*L'Alimentation du Cheval. Paris, 1912, pp. 164*).—A general treatise on this subject which gives recent results of investigations that can be applied by the practical horse feeder.

**The Przewalskii wild horse**, E. WEBER (*Ztschr. Tiermed., 16 (1912), No. 5, pp. 179-192, fig. 1*).—A discussion of the characteristics of *Equus przewalskii*, which the author considers to be the sole ancestor of the domesticated horse. A bibliography is appended.

**The half-bred in Ireland: Hunters, hacks, and army horses**, E. MEULFMAN (*Le Demi-Sang en Irlande: Hunters, Hacks et Troupiers. Paris, 1910, pp. XI+139, pls. 32*).—An account of the past and present conditions of horse breeding in Ireland.

**The Argentine polo ponies** (*Country Life [London], 31 (1912), No. 806, pp. 19\*, 20\*, figs. 4*).—This discusses the type of Argentine ponies which has been recently introduced into England.

**Certification of stallions**, W. A. N. ROBERTSON (*Jour. Dept. Agr. Victoria, 10 (1912), No. 5, pp. 288-315*).—This reports the results of the fifth stallion registration in Victoria, and also states the regulations under which the animals are registered.

**Castration of the stallion standing by means of the ecraseur**, J. J. EDGAR (*Agr. Jour. Union So. Africa, 3 (1912), No. 4, pp. 486-491, figs. 6*).—Directions are given for castration, based on the results of many years' experience.

**Cattle dogs and sheep dogs**, R. KALESKI (*Dept. Agr. N. S. Wales, Farmers' Bul. 38, 1910, pp. 15, pls. 4*).—A discussion of the requirements of good cattle and sheep dogs, and a description of the varieties in New South Wales.

**Proper temperature for artificial incubation**, S. COVALT (*Rel. Poultry Jour., 19 (1912), No. 5, pp. 785, 832*).—The rectal temperature of the fowls examined was as follows: Cockerels, range 105.2 to 107°, with an average of 106.8°; laying hens and pullets, range 104.8 to 107.5°, average 106.6°; sitting hens, range 105 to 107.4°, average 106.1°. The inside temperature of eggs under a sitting hen at the end of 3, 6, 7, and 24 hours was 100°, at the end of a week 101°, at the end of 2 weeks 102.4°, and on the eighteenth day 102°. When a thermometer was hung on a hook in the incubator and kept at 103°, the inside temperature of the eggs after 24 hours' incubation was only 97°. When the thermometer was placed on the eggs and kept at 103°, the inside temperature of the eggs was approximately that of eggs under the hen.

“There is not much change in the temperature of the live chick in the egg after the end of the second week. And in the incubator the live chicks in the eggs showed an average of 102.4° at the end of the eighteenth day with the thermometer running at 103° on the eggs. I consider that the safest and best

place from then on for the thermometer would be hanging on hooks above the eggs and not more than  $\frac{1}{2}$  in. away from them, running a temperature of 103.5 to 104° at hatching time.

"These experiments bring us, I believe, as near as any possible way can to finding the proper temperature at which to run the incubator. One hen had a temperature of 105.4°, and I always found her eggs, on an average, 2° lower than the others. On examining the chicks in these eggs I found they, without exception, showed improper development."

**Poultry keeping in Egypt.** W. H. CADMAN (*Agr. Jour. Egypt*, 1 (1912), No. 2, pp. 66-80).—A brief summary of the poultry industry in Egypt as compared with that of other countries.

**The long-tailed Japanese fowl.** F. L. SEWELL (*Rel. Poultry Jour.*, 19 (1912), No. 5, pp. 775, 802, 803, figs. 9).—A description of the characteristics of this breed of fowl. It is suggested that as the supply of plumage of wild birds is decreasing, it will be profitable to raise this fowl as the long plumes will find a ready sale with milliners.

**Experiments with ostriches.** J. E. DUERDEN (*Agr. Jour. Cape Good Hope*, 37 (1910), No. 5, pp. 512-517; *Agr. Jour. Union So. Africa*, 1 (1911), Nos. 1, pp. 29-37, pls. 8; 3, pp. 348-351; 3 (1911), Nos. 1, pp. 22-29; 3, pp. 352-356, figs. 2; 4, pp. 492-507, figs. 5; 5, pp. 625-638, figs. 5).—A continuation of earlier work (E. S. R., 24, p. 380).

**The plumages of the ostrich.** J. E. DUERDEN (*Ann. Rpt. Smithsn. Inst.*, 1910, pp. 561-571, pls. 8).—This is a reprint of a portion of the work noted above.

**Shellfish industries.** J. L. KELLOGG (*New York*, 1910, pp. XIII+361, pls. 16, figs. 33).—A popular work on the oyster, soft clam, hard clam, and scallop, written for those interested in their culture or who may have an interest in the biological problems involved in their artificial control.

## DAIRY FARMING—DAIRYING.

**Report of the Fifth International Dairy Congress** (*Compt Rend. 5. Cong. Internat. Lait.* [Stockholm], 1911, pp. 176, pl. 1).—This is a complete report of the proceedings and papers read at the International Dairy Congress, held at Stockholm, June and July, 1911.

**Norwegian dairy industry.** P. E. TAYLOR (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 137, pp. 1041-1043).—A brief report on the recent development of the dairy industry in the Stavanger consular district, where most of the creameries are on the cooperative plan and in a profitable condition. A large amount of cheese and butter is exported. The growth of the industry has opened the market for several kinds of American machinery, such as mowing machines, ensilage cutters, dairy appliances, etc.

**The production of milk in Italy.** BIGNAMI (*Villaggio*, 36 (1911), No. 1826, p. 313; *abs. in Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 8-10, p. 2224).—Information regarding the production of milk, butter, and cheese from cows, sheep, and goats in Italy.

**Half yearly exports of milk and dairy products from Italy** (*Statis. Import. e Esport.* [Italy], 1911, Jan.-June, pp. 315; *abs. in Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and Plant Diseases*, 2 (1911), No. 8-10, p. 2225).—Data on milk, butter, and different varieties of cheese exported from Italy in the years 1909-1911.

[**The dairy industry of Tasmania.**] H. D. BAKER (*Daily Cons. and Trade Rpts.* [U. S.], 15 (1912), No. 128, p. 851).—This contains notes on the present condition of the industry. At present about 53,000 cows are kept for dairy purposes. The output of the registered factories during the year ended June

30, 1911, was 2,815,680 lbs. of butter, valued at \$611,719, and 423,920 lbs. of cheese, valued at \$51,487. Most of this cheese and butter was sent to England, via Melbourne.

[Dairying] (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1909-10, pp. 24-31, 47, 63*).—This consists of reports on dairy legislation, inspection of dairy products, and testing glassware, and analyses of butter.

Results of the Douglas County cow testing association, A. L. HAECKER and J. H. FRANSEN (*Nebraska Sta. Bul. 129, pp. 3-15, figs. 6*).—A summary is given of records of a cow-testing association which included 21 herds and 435 cows. Comparisons are drawn between the best and the poorest cows in each herd. The 10 most profitable cows showed a total profit of \$1,032.88, as compared with \$57.82 made by the 10 poorest cows. One cow returned only 55 cts. for each dollar of feed consumed. The best cow returned \$4.17.

Cooperative cow insurance societies in 1910 (*Jour. Bd. Agr. [London], 19 (1912), No. 2, pp. 116-124*).—This reports the number of members, number of animals insured, amount of claims paid, and other data of the 22 cooperative cow insurance societies in England and Wales.

Hand milking, and method of reducing and regulating, P. BERGÉS (*An. Soc. Rural Argentina, 46 (1912), No. 2, pp. 127-159, figs. 18*).—A discussion of the advantages of using milking machines, based principally on the results of their use in foreign countries.

On the cost price of milk in France (*Rev. Sci. [Paris], 49 (1911), II, No. 13, p. 409; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases, 2 (1911), No. 8-10, p. 2223*).—The average cost of milk production in the Department of Yonne is stated to be 0.215 franc per liter (about 3.9 cts. per quart) for small herds and 0.188 franc per liter for large herds.

Milk in India, R. J. BLACKHAM (*Jour. Roy. Army Med. Corps, 16 (1911), No. 2, pp. 187-191*).—The average of 402 analyses of cow's milk gave the following results: Specific gravity 1.03244, total solids 13.393 per cent, and fat 4.286 per cent. Buffalo's milk was found to contain less fat than most of the analyses which have been previously reported. The average of the analyses of 124 samples resulted as follows: Specific gravity, 1.03404, total solids 15.98, and fat 5.98.

The influence of freezing on the composition of milk, C. MAI (*Molk. Ztg. Berlin, 22 (1912), No. 18, pp. 207, 208; N. Y. Produce Rev. and Amer. Cream., 34 (1912), No. 6, p. 262*).—Chemical and physical constants of a number of tests with frozen milk are reported.

In one case a 10-qt. can, kept at a temperature of 21° F. from 6 p. m. to 8 a. m., formed a layer of ice on the inside about the thickness of a finger. The can was then closed and left until the next morning. The upper layer was frozen "foamy leafy," and could be removed with a spoon. After about 4 qt. of the unfrozen liquid in the center was withdrawn, as well as the upper layer, the ice coat on the sides was thawed at 68°, and all remixed. The results of analyses are given in the following table:

*Chemical and physical constants of milk partially frozen at 21° F.*

	Specific gravity.	Refraction number.	Fat.	Solids-not-fat.	Acidity.
			<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
The original milk.....	1.0317	38.5	3.4	8.87	6.5
Upper loose ice.....	1.0233	37.5	11.1	8.57	.....
Solid ice on sides.....	1.0165	28.0	3.2	4.92	.....
Liquid in the center.....	1.0534	52.2	2.0	13.85	.....
All remixed.....	1.0321	38.5	3.3	8.95	7.3

In another case the milk was chilled to 32°, and placed in the open air at a temperature of from 4° above to zero for 30 hours. A small sample was kept unfrozen in an ice-box to control the acidity. The can appeared as before, and after separating and testing the various parts they were left for 3 days at about 39° to thaw and be remixed. The results were as follows:

*Chemical and physical constants of milk partially frozen at 4° F.*

	Specific gravity.	Refraction number.	Fat.	Solids-not-fat.	Acidity.
			<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Original milk.....	1.0318	38.6	3.7	8.94	6.2
Upper layer (0.6 qt.).....	1.0256	40.2	11.6	9.30	8.2
Liquid center (2.5 qt.).....	1.0534	53.5	3.3	14.17	11.0
Solid ice on sides (7 qt.).....	1.0201	30.1	2.9	5.75	3.8
Remixed.....	1.0320	38.7	3.6	8.97	7.2
Unfrozen control.....		38.6			7.0

The milk was not changed by freezing in any manner perceptible to smell or taste, nor to the peroxydase reaction. The author warns the police inspectors to be careful in taking samples of milk in frosty weather, and suggests prohibiting the sale of partially frozen milk.

[A froth dispeller] (*Dairy*, 23 (1911), No. 276, p. 325, fig. 1; *N. Y. Produce Rev. and Amer. Cream.*, 33 (1912), No. 21, p. 88½).—A description is given of a centrifugal machine for separating air from milk and milk froth.

In appearance it resembles the Alfa separator. The milk in its attempt to leave the bowl encounters paddle-shaped ribs in the space between the disks and is sent through this space in a thin layer out of the bowl into the cover, which it leaves by an outlet therein. The air which is separated from the milk escapes from the bowl by passing out of the bottom disk and ascends into the atmosphere. As the milk leaves the machine at a considerable force it can be elevated, if desired, over a cooler without the aid of a pump. The air is prevented from issuing with the milk by means of a regulating tap attached to the milk outlet pipe.

When separating pasteurized milk the froth dispeller is arranged to receive the milk from the pasteurizer and feed it to the separator. When cooling pasteurized milk the froth dispeller receives the milk from the pasteurizer and elevates it over the cooler.

Is it a menace to humans to drink milk obtained from cows affected with tuberculosis of the udder? E. UNGERMANN (*Tuberkulose Arb. K. Gsndhtsamt.*, 1912, No. 12, pp. 213-26¼).—In some cases no traces of tuberculosis could be found in people who were accustomed to use tuberculous milk, though in other instances the results were affirmative. The conclusion is reached that tuberculous milk is a source of infection, but that a still greater danger is the contraction of the disease from human tuberculous patients.

Report from the bacteriological department, 1911-12, J. GOLDING and W. SADLER (*Midland Agr. and Dairy Col. Bul.* 8, 1911-12, pp. 67-78).—This consists of brief notes on defects of milk and milk products.

*Bacillus lactis viscosus* was found to be the cause of a sample of ropy milk. A copper taint in milk was due to the use of a cooler from which the tin had been largely worn off. A burnt taste in milk was traced to the presence of *Bacterium lactis acidit*. Milk sold as sterilized had turned yellow and was found to contain a spindle-shaped organism, forming large spores quite resistant to heat. A yellow discoloration of Stilton cheese was ascribed to the presence of an abnormal amount of tyrosin.

**South Italian cheeses**, C. BESANA (*Ann. R. Staz. Sper. Caseif. Lodi*, 1910, pp. 49-78; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intcl. and Plant Diseases*, 2 (1911), No. 8-10, pp. 2230, 2231).—Descriptions are presented of the principal varieties of cheese as made in southern Italy.

The most popular variety is Pecorino, made of ewe's milk. Among the types of cow's milk cheeses are Provolone, a good table cheese, Caciocavallo, which is often used for grating, and Scamorze a small salted cheese, which is consumed locally. Although good cheeses are made for home consumption, they are not an important commercial product. Provature, or Provole, and Mozzarella cheeses are made from buffalo milk. Many cheeses from mixed milk are made and consumed locally. Manteche is whey butter, covered with a thin layer of cheese.

**Yellow discoloration of Stilton cheese**, J. GOLDING (*Jour. Bd. Agr. [London]*, 19 (1912), No. 3, pp. 177-186, pl. 1).—This discusses the losses caused by a yellow discoloration of Stilton cheese, and reports the results of the investigations to determine the cause.

Twenty-four cheeses were made under control conditions, with the result that those containing a large amount of salt seemed to favor the yellow discoloration, but evidently this was not the only factor. Negative results were obtained with pure cultures of bacteria. The injection of tyrosin into the normal cheeses produced discoloration, and therefore is thought to be the limiting factor. Salt is also thought to favor the accumulation of tyrosin because it retards the action of enzymes that might destroy tyrosin formed during ripening. To avoid this defect cleanliness should be observed, especially in the preparation of the rennet, so that unfavorable types of bacteria or other active agents which influence the formation of tyrosin may be excluded.

## VETERINARY MEDICINE.

**Report of the veterinarian for the State of Pennsylvania**, S. H. GILLILAND (*Ann. Rpt. Penn. Dept. Agr.*, 16 (1910), pp. 136-195).—This is a report for the year 1910 with reference to the meat inspection service, meat markets, slaughterhouses, diseases of live stock, a report of the bacteriological laboratory, results obtained in the eradication of tuberculosis (noted on page 481), the diagnosis of rabies (noted on page 479), and microscopical examinations of miscellaneous materials.

**Annual report for 1911 of the principal of the Royal Veterinary College**, J. McFADYEAN (*Jour. Roy. Agr. Soc. England*, 72 (1911), pp. 347-362).—The diseases reported upon are anthrax, glanders, hog cholera, foot-and-mouth disease, parasitic gastritis in sheep, and tuberculosis.

**Annual report of the Punjab Veterinary College and of the Civil Veterinary Department, Punjab, for the year 1910-11**, S. H. GAIGER and V. DE V. H. WOODLEY (*Ann. Rpt. Punjab Vet. Col. and Civ. Vet. Dept.*, 1910-11, pp. 14+XII).—This annual report includes accounts of the occurrence of equine and bovine contagious diseases, breeding operations, etc.

**Report of the government bacteriologist**, C. J. POUND (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1910-11, pp. 62-68, pl. 1).—This report consists largely of a discussion of tick fever and its prevention by inoculation. The parasite *Onchoerca gibsoni* is reported to have been found during the early part of the year in sheep, an animal which hitherto was not suspected of harboring this parasite.

**Surgical and obstetrical operations**, W. L. WILLIAMS (*Ithaca, N. Y.*, 1912, 3. ed., rev. and enl., pp. XII+240, pls. 40, figs. 18).—A third revised and enlarged edition of this work (E. S. R., 15, p. 719).

Practical and scientific horseshoeing, F. G. CHURCHILL (*Kansas City, Mo., 1912, pp. 127, pls. 7*).—A small handbook.

Subject and author index to *Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten*, E. RIEHM (*Centbl. Bakt. [etc.]*, 2. Abt., *General-Register für die Bände 21-30. Jena, 1911, pp. 393*).—This is the author and subject index of this publication for volumes 21 to 30, inclusive.

The bacterial cell, A. MEYER (*Die Zelle der Bakterien. Jena, 1912, pp. VI+285, pl. 1, figs. 34*).—This is a comparative and critical compilation of the knowledge in regard to the bacterial cell, and is meant for botanists, zoologists, and bacteriologists.

On the transmission of immunity from mother to offspring.—A study upon serum hemolysins in goats, F. W. FAMULENER (*Jour. Infect. Discases, 10 (1912), No. 3, pp. 332-368*).—To summarize briefly the principal results of the experiments, it was found that goats actively immunized against sheep blood corpuscles during gestation passively transmitted the specific hemolysin to their young. Colostrum was the chief agent in bringing about the passive immunization of the suckling. Sucklings which got the colostrum and first milk rapidly acquired a relatively high antibody content in their blood, which was well retained. When the immunization was done during the period of gestation the colostrum contained a high content of specific hemolysin, often much higher than the adult's serum at time of parturition. The hemolytic antibodies rapidly disappeared from the milk after the mother had been suckled by the young. The blood taken from the newly born before they were permitted the antibody colostrum showed no appreciable amount of hemolysin by the test used. The placenta played a minor rôle in the passage of hemolysins to young before birth, practically negligible in most cases. Mother goats, actively immunized against sheep-blood corpuscles immediately after birth of their young, failed to transmit any demonstrable immunity to their suckling young. The milk, in some cases, contained no demonstrable hemolysins, but in others showed fairly large amounts. Apparently a very high degree of immunity is necessary before appreciable amounts of antibodies are excreted through the milk. Older sucklings apparently did not absorb the antibodies in an unchanged condition. The young animals (kids) did not respond to any extent in production of hemolysins following subcutaneous injections of foreign blood cells (sheep)."

The production and valuation of curative sera, K. E. BOEHNCKE (*Ztschr. Angew. Chem., 25 (1912), No. 18, pp. 865-870*).—A simple and concrete discussion of the facts pertaining to the production and testing of curative sera.

The optical method and its use in serum diagnosis, H. MIESSNER and K. B. IMMISCH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 4 (1912), No. 3, pp. 160-187, fig. 1*).—This is a study of the optical behavior of normal and abnormal sera from various animals. The changes produced in the rotation as observed in the polariscope by silk-normal serum and glanders serum peptones and glanders bacilli extracts in a mixture with the serum of diseased horses were very atypical and did not greatly differentiate themselves from the value obtained for the sera from normal animals. Therefore the optical method is not considered an efficient method for diagnosing disease, especially where glanders is concerned and peptone mixtures are employed.

Dipping and tick destroying agents, H. WATKINS-PITCHFORD (*Agr. Jour. Union So. Africa, 2 (1911), No. 1, pp. 33-79, pls. 2, figs. 4*).—This is a report of dipping experiments, etc., with the brown tick (*Rhipicephalus appendiculatus*), which transmits the virus of East Coast fever, conducted in continuation of those previously noted (*E. S. R., 24, p. 393*). The investigations reported include the following subjects: Shortest periods for engorgement of the larva

and nymph of the brown tick; details of adjustment of the 3-day dip; lethal effects of 3-day and laboratory dips on distended female brown ticks; the effect of 3-day dip at intervals of 72 hours upon adult tick life generally; the lethal effect of dips ( $\frac{1}{2}$  and  $\frac{5}{8}$  strengths) at intervals of 48 hours, showing the increase of efficiency resulting from the addition of soap and paraffin; details for preparation of 3-day dipping fluid; details for preparation of 3-day ear dressing; tick migration experiment; relative tick activity during day and night; residual effect of 3-day dip in horses and cattle; the agency of the tail tuft in the collection of ticks; the suitability of 3-day dip in the treatment of scab in sheep; effect of weekly dipping process with laboratory dip upon secretion of milk; and a description of the isometer devised by the author for use in the estimation of the exact percentages of arsenic present in different samples of dipping fluid.

On the blood parasites found in animals in the zoological gardens during the four years 1908-1911, H. G. PLIMMER (*Proc. Zool. Soc. London, 1912, II, pp. 406-419, pls. 7*).—During a period of 4 years the author examined the blood of every mammal, bird, reptile, and batrachian, which died in the zoological gardens, a total of 6,430 individuals. Blood parasites were found in 447, or about 7 per cent; these animals representing 256 species. The results are reported in detail.

Amebæ as the cause of disease in domestic animals, E. LEHMANN (*Centbl. Bakl. [etc.], I. Abt., Orig., 62 (1912), No. 7, pp. 589-605, figs. 14*).—A brief review first presented is followed by a report of studies of amebic dysentery in the horse, amebæ in the walls of the fore-stomachs of bovines, and amebæ colonies in the intestines of sheep. A bibliography of 61 titles is appended.

A contribution to the pathogenesis of *B. abortus*, Bang, II, M. FABYAN (*Jour. Med. Research, 26 (1912), No. 3, pp. 441-487, pls. 7*).—In the first part of this paper (*E. S. R., 26, p. 586*) the author presents a historical review of investigations of the etiology of contagious abortion. A report of investigations of the disease produced by inoculating guinea pigs follows.

"*Bacillus abortus* may be said to cause lesions in guinea pigs of a practically constant and most remarkable character. These usually appear between the third and sixth week (within 10 days as determined in sections by the microscope), the acute changes extending over a period of 10 to 20 weeks, after which reparative processes appear. The disease is accompanied by fever and tends toward final recovery, though the animal may die from rupture of the spleen, emaciation, and exhaustion.

"All the tissues of the body may be attacked with the exception of the muscles. This universality and frequency is best seen in sections under the microscope, as only the far advanced lesions are recognized by the unaided eye. In the tissues involved and in the histological changes produced, the disease closely resembles tuberculosis. The lesions have a predilection for the perivascular and subcapsular regions of the various organs. Injections cause at first a profound disturbance of the circulation in certain organs, notably the spleen, which becomes enormously engorged. Intra-abdominal inoculations are frequently followed by adhesions about the spleen. The localization of the disease in the testicle as well as in other organs, even when *B. abortus* is inoculated subcutaneously, is quite remarkable. The proliferation of bone although not common is extraordinary when present."

Inoculations led the author to conclude that it is highly probable that *B. abortus* produces lesions in mice.

The cultivation of *B. abortus* is described at length: "The cultural characteristics of this organism are quite constant when once its ability to grow on artificial media has been established. Among these characteristics may be

mentioned the glistening iridescent colonies on agar and the variation in their size; the colonies on and the nonliquefaction of gelatin; the slow growth in bouillon; the conspicuous pigmented growth on potato; and the organism's inability to ferment dextrose, saccharose, or lactose, or to produce acid."

**Infectious abortion in bovines**, ZWICK (*Deut. Tierärztl. Wchnschr.*, 19 (1911), No. 51, pp. 781-785; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 5 (1912), No. 1, p. 855).—This work, a portion of which has been previously noted (*E. S. R.*, 24, p. 785), shows that the serum of cows which have aborted, taken at the time or shortly after, will agglutinate in a titer of from 1:100 to 1:10,000, while normal animals' serum will never agglutinate over a titer of 1:100. A complement fixation test is obtained with the serum of cows which aborted, in amounts of from 0.01 to 0.001 cc., while the serum of normal animals requires amounts varying from 0.02 to 0.1.

As the abortion bacillus when taken with the food will also produce specific antibodies, and the immune bodies remain for a long time in the serum, this finding will only show that the animals are or were infected. Abortin prepared according to procedures used for producing tuberculin does not yield constant results. It is possible to produce highly active immune serum, and active immunization is possible, although the author believes it is a good procedure to combine the active immunization process with immune serum injections.

**Contribution to Ascoli's precipitant diagnosis of anthrax**, F. RUPPERT (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 4 (1912), No. 3, pp. 243-247).—After pointing out the fact that Ascoli's serum often gives a slight ring when testing with material free from anthrax, as noted by Markoff (*E. S. R.*, 27, p. 182), the author reports several cases in which a negative reaction was obtained with positively anthracic material. The method could not be employed for detecting anthrax bacteria or spores in foodstuffs.

**Tests and observations of methods for combating foot-and-mouth disease**, E. KRONACHER (*Deut. Landw. Tierzucht*, 16 (1912), No. 11, pp. 122-124).—The preparations used in these tests were Krafft's vaccine (for protective and curative treatment), Hoffmann's euguform (for treating animals already diseased), euformal, which is a chemical combination of 18 per cent of formaldehyde and 82 per cent of dextrin (for preventing infection), antiformin, pyoktanin, acetic acid and clay, and mitisol. None of these preparations gave very satisfactory results, with the possible exception of pyoktanin, which when used in connection with acetic acid and clay, gave fair results.

**Serum diagnosis of glanders and other animal diseases**, J. R. MOHLER (*Rpt. U. S. Live Stock Sanit. Assoc.*, 15 (1911), pp. 165-172).—A discussion of the mallein reaction, complement fixation test, and the combined complement fixation and agglutination test, accompanied by a report of the results obtained in the various States. The combined test is the one recommended. See also a previous note (*E. S. R.*, 27, p. 183).

**Observations and investigations of infectious ostitis and osteomyelitis in the ox and horse**, A. BAUMGARTNER (*Schweiz. Arch. Tierheilk.*, 53 (1911), No. 3, pp. 107-123, pls. 4, figs. 3).—The author's observations and investigations have led to the following conclusions:

There is in the horse and bovine a very painful ostitis and osteomyelitis, caused by the necrosis bacterium alone or in symbiosis with a gram-positive coccus. It results in an uninterrupted motor disturbance of the most marked type, a skeletal lameness, an increased pulse rate, and often somewhat fever, but without affecting the appetite. In some cases abscess formation follows. The disease has a very destructive effect upon the bones without reactive osteophyte formation, therefore hypertrophy of the bone is never observed. The course is mostly slow and long continued. Iodin preparations have a

highly curative effect. Hitherto this disease has occasionally been classed with rheumatism.

The dissemination and action of the *Pentastomum tænioides*, S. VON RÁTZ (*Allatorrosi Lapok*, 34 (1911), No. 41, pp. 485-488; *abs. in Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 8, p. 141; *Vet. Rec.*, 24 (1912), No. 1236, pp. 582, 583).—The adult of *P. tænioides* lives in the nasal cavities of the dog, wolf, and fox, and is also found in the same position in herbivora. "The larvæ occur in the thoracic and abdominal viscera, for the most part in the liver, lungs, and mesenteric lymphatic glands, and are often found free in the pleural and peritoneal cavities of the hare, guinea pig, goat, sheep, horse, ox, pig, deer, cat, etc., in addition to those of man. . . . The ripe ova pass out from the host's nose on to plants, and with them into the stomach of (usually) herbivora. Here the embryos, and later the larvæ, penetrate the intestinal wall into the blood and lymph vessels, and pass in these to the different organs, where the larva (formerly known as *L. serrata* or *P. denticulatum*) develops further. Afterwards it becomes encysted or wanders farther into the serous cavities. The author's results do not support the view formerly held of the active wanderings of the Linguatula in the bronchi.

"Infection in carnivora occurs as follows: Carnivorous animals take up the larvæ of the parasite with the lungs, liver, etc., which they devour. The larvæ wander from the stomach through the esophagus into the mouth, and thence into the nasal cavity. Moreover, when infected food is swallowed, single free larvæ may adhere to the palate and from there migrate into the nasal cavity. Finally, the author has experimentally proved that animals may acquire young Linguatulae in their nostrils by smelling at organs containing larvæ.

"When in the nasal cavities the parasite causes bleeding. More rarely it occasions violent inflammation and nervous symptoms resembling those of rabies."

The diagnosis of rabies, J. REICHEL (*Ann. Rpt. Penn. Dept. Agr.*, 16 (1910), pp. 179-195).—The usual history, symptoms, gross appearance after death, laboratory examination, animal inoculation test, microscopic examination, and rules regulating the examination and diagnosis are considered.

Investigations of and tick eradication in Rocky Mountain spotted fever, T. B. McCLINTIC (*Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts.*, 27 (1912), No. 20, pp. 732-760).—The work of eradicating the Rocky Mountain spotted fever tick, conducted in cooperation with the State Board of Health of Montana, was begun May 26, 1911, an infected territory of about 8 square miles in the Bitter Root Valley, located about 3 miles from Victor, Mont., being selected for the work. A concrete dipping vat was constructed and 116 horses, 199 cattle, and 108 sheep were dipped and 155 redipped. Some 3,465 small wild animals, of which 3,233 were ground squirrels, were killed by shooting and trapping, and in addition many were killed by poison or carbon bisulphid.

"Out of a total of 4 badgers that were experimented with only 1 of them was found susceptible to infection with spotted fever, and of 5 guinea pigs that were inoculated with blood taken from this badger at 3 different times only 1 of them developed spotted fever. . . . The results with experiments of infecting 5 coyotes and 4 domestic cats were negative. . . . Only 2 weasels were experimented with, 1 of which was experimentally infected with spotted fever while the results obtained in the case of the other were negative but not conclusive." In a search made for the infection of spotted fever among ground squirrels in nature the results were negative.

"Rhesus monkeys and guinea pigs were infected with spotted fever and treated with different drug preparations, namely, Salvarsan, sodium cacodylate,

and urotropin. The results obtained, however, do not indicate that any of these drugs possess any value whatever either as a prophylactic or in the treatment of spotted fever, but on the contrary their administration seems on the whole rather to intensify the severity of the disease in the animals as compared with the course of the disease in the controls."

A bibliography of 76 titles is appended.

Agglutination, precipitation, and complement fixation as an aid for diagnosing trypanosome diseases, especially dourine (*Beschälseuche*), WINKLER and S. WYSCHALESSKY (*Berlin. Tierärztl. Wchnschr.*, 27 (1911), No. 51, pp. 933-936).—The above mentioned reactions can be used for diagnosing these conditions.

[Transmission of *Trypanosoma hippicum*] (*Rpt. Dept. Sanit. Isthmian Canal Com., 1912, Feb., pp. 41-43*).—Experiments here reported "indicate very positively that *T. hippicum* can penetrate the mucosa of nules, which in the mouth and vagina is much thicker in proportion to the length of trypanosome than that of guinea pigs and rats used in other experiments, and it is assumed from this that murrina may be transmitted during copulation."

[Investigations of *Trypanosoma hippicum*] (*Rpt. Dept. Sanit. Isthmian Canal Com., 1912, May, pp. 41-43*).—"A strain of *T. hippicum* that had survived in a guinea pig the exceptionally long period of 336 days showed upon sub-inoculation on the two hundred and seventy-ninth and three hundred and thirty-sixth days very feeble pathogenic powers when compared with all other strains and with the same strain at an earlier period of the infection in the guinea pig."

Diagnosis, prevention, and treatment of tuberculosis, S. J. BONANSEA (*Diagnóstico, Prevención, y Curación de la Tuberculosis. Mexico, 1911, pp. 344, figs. 23*).—This is a general summary of the methods of diagnosing, preventing, and treating tuberculosis in animals. Mexican conditions are considered in particular.

The relation between human and animal tuberculosis, H. KOSSEL (*Deut. Med. Wchnschr.*, 38 (1912), No. 16, pp. 740-744).—In an address before the Seventh International Tuberculosis Congress, held at Rome, the author maintains that the greatest source of infection for pulmonary tuberculosis in man is man himself, particularly because the human type of bacillus is almost always present. Very little tuberculosis has its origin from the consumption of milk and meat obtained from tuberculous animals. Therefore, when combating tuberculosis as a national disease it is necessary to direct efforts principally to human infection.

In regard to bovine and human tuberculosis, J. ORTH (*Sitzber. K. Preuss. Akad. Wiss., 1912, VII, pp. 155-179*).—A critical and historical discussion. Great stress is laid upon the point that tuberculosis in the human race can never be eliminated as long as the bovine type of the bacilli is conveyed from animal to man.

Differentiating the human type of tubercle bacillus from the bovine type by cutaneous injection of the guinea pig, E. TOMARKIN and S. PESCHIC (*Deut. Med. Wchnschr.*, 38 (1912), No. 22, pp. 1032-1034).—More skin infections were obtained (through shaved but intact skin) with the bovine type of bacillus (26 out of 26 animals) than with the human type (7 out of 52 animals). The method can therefore be used for differential diagnosis.

The presence of tubercle bacilli in the circulating blood.—The elimination of tubercle bacilli in the milk of tuberculous women, T. KURASHIGE, R. MAYEYAMA, and G. YAMADA (*Ztschr. Tuberkulose, 18 (1912), No. 5, pp. 433-445*).—The elimination of tubercle bacilli in the milk of 20 tuberculous women, and in 2 cases which apparently were nontuberculous, was noted. The chief

source of the bacilli was the circulating blood. See also a previous note (E. S. R., 26, p. 281).

The specific antibodies in the blood serum of tuberculous subjects, B. MÖLLERS (*Deut. Med. Wchnschr.*, 38 (1912), No. 16, pp. 745, 746).—The author maintains that for the early diagnosis of tuberculosis the serological tests thus far proposed can not be used in actual practice, and accordingly can not supplant the Koch subcutaneous reaction or the von Pirquet test.

Complement fixing bodies can be artificially produced in animals sensitive to tuberculosis just as they are produced in man by injecting large doses of tuberculin preparations. The best method of doing this, however, consists of injecting killed intact whole bacteria. The appearance of complement fixing bodies in the blood serum is an indication that a change is taking place in the humoral tissues, but whether this change has any significance as far as curing the disease is concerned must, according to the author, remain an open question. A positive prognostic significance can not be attributed to the complement fixing antibodies.

Examination of the feces of tubercular and nontubercular cattle, S. H. GILLILAND (*Ann. Rpt. Penn. Dept. Agr.*, 16 (1910), pp. 157-165).—These experiments included tuberculin-reacting cattle with physical symptoms of tuberculosis, tuberculin-reacting cattle showing no physical symptoms of tuberculosis, and immunized cattle free of tuberculosis.

It was shown as a result of these tests that the microscopic examination of feces or rectal scrapings of cattle is of no value for detecting tubercle bacilli, because many bacteria are present in the feces which have the appearance and staining properties of the tubercle bacillus but which in the end do not prove themselves to be such. The animal inoculation test when applied in this direction is a valuable but not an infallible test. "Of the 40 cattle included in the examination, 9 (22.5 per cent) were found to be throwing off virulent tubercle bacilli in the feces or rectal scrapings. Of these 9 cattle, the tubercle bacilli were found virulent for guinea pigs, and in 8 of 9, the tubercle bacilli were virulent for rabbits."

Where the bacteria detected in the rectal scrapings, etc., have been proved to be tubercle bacilli, proof is presented that either an open tuberculosis exists or tubercle bacilli are passed through the length of the alimentary tract. "The demonstration of tubercle bacilli in the feces or rectal scrapings of cattle apparently free of tuberculosis, but stabled with highly infected cattle, may be accepted as an indication that tubercle bacilli are passing through such cattle, the tubercle bacilli being ingested and thrown off in numbers large enough to be demonstrable in the feces or rectal scrapings. . . . Tuberculin-reacting cattle do not necessarily throw off tubercle bacilli in the feces until the development of 'open' lesions of tuberculosis, in which event the condition may be detected by a consideration of the history, careful observation, and a complete physical examination."

See also a previous note (E. S. R., 27, p. 382).

Results obtained with the conjunctival reaction with tuberculin, as well as the local tuberculin reaction with bovines, A. WOLFF-EISNER (*Ztschr. Tiermed.*, 15 (1911), No. 1, pp. 1-49; *abs. in Ztschr. Tuberkulose*, 18 (1912), No. 5, pp. 494, 495).—After a study of the reaction with a large number of bovines the conclusion is reached that it is more satisfactory than the subcutaneous test. An exact statement of the procedure as followed by the author is given. A 40 to 50 per cent solution of tuberculin (bovotuberculin and a dried tuberculin) was employed. Two or 3 instillations are given for the purpose of controlling the reaction.

Combating bovine tuberculosis according to the new epizootic laws in Germany, E. SCHARR (*Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 20, pp. 349-353).—A discussion of the methods for diagnosing tuberculosis in bovines in Germany. Various phases of the law are critically discussed, including the reimbursing of the owner of tuberculous cattle.

Experience in eradicating tuberculosis from a herd, N. S. MAYO (*Rpt. U. S. Live Stock Sanit. Assoc.*, 15 (1911), pp. 186-191).—This is a brief history of an outbreak of tuberculosis in the herd of the Virginia Polytechnic Institute, together with advice in regard to eradicating tuberculosis from herds.

Cultivation of the bacillus of chronic intestinal inflammation of the bovine (paratubercle bacillus), H. HOLTH (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 11 (1912), No. 5, pp. 378-387, figs. 6; *abs. in Jour. Compar. Path. and Ther.*, 25 (1912), No. 2, pp. 148-150).—In the author's investigation of John's disease cultures obtained from a case which reacted to avian tuberculin were planted upon 7 types of media. The most abundant growth was obtained on media consisting of blood serum with  $\frac{1}{4}$  volume of liver broth, 2 per cent dead tubercle bacilli, and 4 per cent glycerin.

"At 6 weeks the whole surface of the medium was covered with colonies that were visible to the naked eye, and which later attained a size varying from  $\frac{1}{8}$  to 1 mm. By reflected light the colonies were greyish-white in color, and by transmitted light yellowish-brown. They were circular in outline, and under a low magnification the surface was observed to present a slightly wrinkled appearance. The colonies were tough. In older cultures there was observed the formation of a thin delicate membrane of wrinkled growth extending round the colonies. Growth on the other media presented similar appearances, but developed more slowly. Subcultures on the same medium yielded quite abundant growth in about 4 weeks."

The inoculation of guinea pigs failed to induce the disease, producing at most a small encapsuled abscess at the seat of inoculation, the contents of which contained a few granular acid-fast bacilli. Experiments with rabbits gave similar results. In experiments with tuberculin-tested calves, inoculations made subcutaneously and intravenously caused no reaction. Three months later the calves were tested with ordinary tuberculin and did not react but with avian tuberculin typical reactions were obtained at the end of 3 weeks.

"Experiments were carried out with guinea pigs with the object of ascertaining whether John's bacillus is capable of conferring any immunity against tuberculosis. The animals received 2 comparatively large doses of culture, and a month later a dose of bacilli of the bovine type. Control animals were inoculated with the bovine bacilli alone. All the animals were weighed twice weekly, and it was found that the control animals commenced to lose weight sooner than the others. The author concludes that a slight degree of immunity was established."

The anaplasmoses of cattle, L. E. W. BEVAN (*Vet. Jour.*, 68 (1912), No. 445 pp. 392-400).—This is a general discussion of the subject. It is pointed out that while trypanblue is invaluable in checking piroplasmiasis it is ineffective against anaplasmosis, which in the present state of our knowledge can be combated only by careful nursing and a diet which can be digested, assimilated, and made use of to replace and repair the loss of tissue caused by the disease.

Anaplasmosis of sheep, L. E. W. BEVAN (*Vet. Jour.*, 68 (1912), No. 445, pp. 400, 401).—The author reports the occurrence of this disease among sheep. He states that it has a wide distribution throughout Rhodesia.

In regard to a vaccine prepared by a new method against hog cholera and swine plague, KRAFFT (*Berlin. Tierärztl. Wehnschr.*, 28 (1912), No. 15, pp. 261-266).—The preparation of the vaccine is based on the following principle:

To warmed mixtures of highly virulent organisms certain metals are added for reducing the virulency of the micro-organisms, since micro-organisms so attenuated, when injected into animals, can be borne with impunity. Metallic salts in solution can not be used for this purpose on account of their toxicity. The vaccines prepared according to the above principle are employed by the author for immunizing purposes. The results of tests conducted with the vaccines prepared in this manner on mice, guinea pigs, rabbits, and shoats are reported, and showed good immunizing properties.

The vaccine for swine plague was prepared from *Bacillus suisepiticus*, while that against hog cholera was produced with *B. suispestifer*. Some tests were also conducted, although very vaguely reported, with a vaccine prepared from *B. suispestifer* and the filtered blood from cases of hog cholera (also organ filtrates) which were exposed to the action of metals. The results of tests in veterinary practice showed that the latter preparation gave better results than those obtained with the *B. suispestifer* vaccine alone.

The diphtheria of suckling pigs, E. WYSSMANN (*Schweiz. Arch. Tierheilk.*, 52 (1910), No. 2, pp. 99-120; *abs. in Berlin. Tierärztl. Wehnschr.*, 27 (1911), No. 33, pp. 596, 597).—After describing the symptoms of this condition and the Guillebeau diphtheria bacillus which is usually present in the nasal and similar mucous membranes, the author states that this condition is either a special form of hog cholera where the diphtheria bacillus plays a secondary part, or a diphtheria proper.

## RURAL ENGINEERING.

Private irrigation enterprise compared with government reclamation, F. G. TRACY ([*Denver*, 1912], pp. 31).—The author presents the opinion that the real meaning of the Reclamation Act has been misconstrued, and he attempts to show by tables of census data that private irrigation projects under the Carey Act have accomplished considerably more for less money than the Reclamation projects in the various States.

Irrigation and irrigating canals (*Rpt. Cal. Bd. Agr.*, 1911, pp. 205-223).—This report briefly reviews the history of irrigation in California, discusses the reclamation works, dry farming, and private irrigation districts and systems, and describes the rivers, creeks, and lakes of the State, giving data of stream flow, drainage, and run-off in the different basins and drainage areas. Tabulated comparisons of irrigated farms and lands in different localities are also included.

Electric irrigation pumping in southern California (*Elect. World*, 59 (1912), No. 23, pp. 1255-1259, figs. 8).—A description is given of the use of electric pumps in the Pomona district.

About 125 electrically-driven irrigation pumping plants are operating within a radius of 10 miles, practically all the energy being supplied by a substation in the city of Pomona, connected with the general transmission of a power company by two 3-phase, 33,000 volt lines, the potential being reduced from 33,000 to 10,000 volts for local distribution among the ranches. The plants are designed for both deep-well and low-lift service, depending on local conditions, using 4 to 5 in. centrifugal pumps for the shorter lifts and double-acting cylinder pumps for the deep-well service. The cost varies from 2 to 3 cts. per kilowatt hour.

[**Drainage problems in West Tennessee**], L. L. HIDINGER and A. E. MORGAN (*Resources Tenn.*, 2 (1912), No. 6, pp. 231-249, pls. 2, figs. 2).—A report on the drainage problems of the Wolf, Hatchie, and the South Fork of the Forked Deer rivers in West Tennessee, which drain approximately 4,815 square miles,

including plans of improvements, maps of surveys, descriptions of stream basins and adjacent drained territory, discussions of methods of reclamation by surface drainage with levees and by ditches, and plans for conveying ditch water under stream beds, levees, and main drainage channels by means of inverted siphons and concrete culverts.

The information indicates that channels should be large enough to carry a run-off of 1 in. in depth from the entire area drained by the river for large areas and somewhat larger for small areas where an excavated channel is economical. Where the volume of water is so great as to make undersurface channels too expensive, levees should be constructed sufficient to provide for a run-off of from  $1\frac{1}{2}$  to 2 in. per 24 hours from the entire watershed. The cost of the works approximates from \$25 to \$30 per acre.

[A tile drainage project] (*Brick and Clay Rec.*, 40 (1912), No. 11, pp. 479-482, figs. 11).—A discussion of the planning and construction of a tile drainage system, reclaiming 500 acres of land on the Desplaines River in Illinois, in which work 250 carloads of tile and 2 years' time were consumed, and 65.3 miles of tile drains constructed. The cost of draining was approximately \$75 per acre.

Practical road building, J. N. EBY (*Municipal Engin.*, 42 (1912), Nos. 4, pp. 215, 216; 5, pp. 351-354, fig. 1; 6, pp. 436-439, fig. 1).—Brief specifications are given for the construction of sand-clay roads on a sand or clay subsurface and for the construction of gravel and macadam roads. Directions for the maintenance of these roads are also presented.

Road building with convict labor, D. GLASS (*Country Gent.*, 77 (1912), No. 16, pp. 3, 30, fig. 1).—The successful and economical use of convict labor for road building in Georgia is noted, the cost being found to be much cheaper than that of other labor. Chert roads have been built at a cost of from \$4,000 to \$5,000 per mile, while a sand and clay road costs from \$400 to \$500 per mile.

First report of the proceedings of the road board for the period from May 13, 1910 to June 30, 1911 (*Rpt. Proc. Road Bd.* [Gt. Brit.], 1 (1910-11), pp. 69).—A report on the existing physical and financial conditions of roads in the United Kingdom.

A new English tar tester (*Good Roads*, n. ser., 3 (1912), No. 22, p. 337, fig. 1).—A device is described which is intended to furnish a quick and easy method of testing bituminous materials to be used in road repair and construction. The instrument consists of a 9-in. stem carrying a weight, bulb, and 2 rings marking the beginning and end of the test. The test is based on the speed with which the instrument sinks in the liquid under examination.

Concrete costs, F. W. TAYLOR and S. E. THOMPSON (*New York and London*, 1912, pp. XXII+709, pl. 1, figs. 76).—This book gives tables and recommendations for estimating the time and cost of labor operations in concrete construction and for introducing economical methods of management.

Farm blacksmithing, G. BAXTER (*Jour. Dept. Agr. Victoria*, 9 (1911), Nos. 7, pp. 479-482; 8, pp. 545-549; 9, pp. 610-615; 10, pp. 685-689; 11, pp. 739-743; 12, pp. 795-799; 10 (1912), Nos. 1, pp. 49-54; 2, pp. 123-127; 3, pp. 192-195; 4, pp. 217-221, figs. 59).—It is the object of this article to instruct the farmer how to lay out a blacksmith shop and make simple and useful articles connected with farm work and farm machinery. The required tools are enumerated and the processes of forging, welding, etc., are discussed in detail.

[Experience with farm powers], R. E. GUNN (*Farm and Dairy [Ontario]*, 31 (1912), No. 23, pp. 609, 617, fig. 1).—The author relates his experience with the use of gasoline, steam, wind, and electric power on his farm, and states that electric power has supplanted all others.

**How horsepower is to be computed** (*Farm Machinery*, 1912, No. 1077, pp. 15, 17).—A general discussion of the methods of computing the power and efficiency of machinery with special reference to agricultural tractors, explaining the actual difference between indicated and brake horsepower, and stating as the factors to be considered in a comparison of the tractive horsepower of engines, the mean effective pressure, piston area and speed, dead weight of engine, and ground surface.

**What electricity will do for the farmer** (*Conn. Farmer*, 42 (1912), No. 21, p. 9).—Results of tests made on farms by a corps of engineers from an electrical appliance company are given, showing the different amounts of work done in a given time by different farm machines driven by electricity and the cost of the operation in each case.

**An experience with electric motors**, D. R. PALMQUIST (*Country Gent.*, 77 (1912), No. 23, p. 5, figs. 2).—Some actual cost figures for the work done by a 15-horsepower portable motor on an average farm are given and compared with the costs of doing the work by other methods. The motor cost \$260 and the power was supplied at 3 cts. per kilowatt hour. Some of the comparisons are as follows: 1,700 bu. of grain were threshed for \$6.60, the cost of doing this by steam or gas tractor being \$9; 4,000 bu. of corn were ground for \$160, the cost at the nearest mill being \$308; and fodder shredding cost \$2.74 per ton, a neighborhood custom machine charging \$3 per ton.

**Electric farm lighting plant installation**, G. D. HARRIS (*Gas Engine*, 14 (1912), No. 6, pp. 332-335, figs. 2).—A brief discussion of the practicability of small lighting plants, their successful operation, and the size, equipment, and cost of a plant most applicable to the average farm.

[Tests of implements], G. FISCHER ET AL. (*Arb. Deut. Landw. Gesell.*, 1911, No. 199, pp. 80, figs. 63).—Descriptions and the methods and results of competitive tests are given of subsoil plows and pond-weeding machinery, with the results of preliminary examinations of several improved agricultural implements, among which are improved manure spreaders, rollers, straw presses, potato diggers, turnip headers, cultivators, mowers, and stump pullers, and the results of individual tests of subsoil packers, motor threshers, manure spreaders, and road tractors.

**A new driving wheel for power plowing outfits**, A. M. LEONI (*Gas Engine*, 14 (1912), No. 6, pp. 316-318, figs. 3).—A driving wheel is described which is equipped with a number of spades, and operated by an eccentric in such a way that with the rotation of the wheel they are pushed into the soil vertically, one after another, providing fixed points of power application for the forward movement of the vehicle and causing a minimum loss of energy.

**Automobile mowing machines and motor-driven mowers**, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 23 (1912), No. 19, pp. 592-594).—These 2 types of machine and their operation are described. It is claimed that with the automobile mower about 4,000 square meters (about 1 acre) of hay or other forage can be mowed in an hour. The motor-driven mowing machine requires 1 man and only 1 horse to do the work of an ordinary 2-horse machine.

**Trials with small self-cleaning threshing machines, 1911**, C. V. BIRK and C. L. FEILBERG (*Tidsskr. Landökonomi*, 1912, No. 3, pp. 161-224, figs. 11).—Eighteen different machines were examined and tested by the committee on machinery trials of the Royal Danish Agricultural Society. The report gives the results of the trials and the judgment of the committee as to the strong and weak points of the different machines.

**Spraying apparatus**, H. A. SURFACE (*Bi-Mo. Zool. Bul. Penn. Dept. Agr.*, 2 (1912), No. 2, pp. 68-77, pls. 5).—A general discussion is given of apparatus for spraying orchards and field crops, including descriptions of various types

of hand and power sprayers. Considerable information is presented relative to the selection of spraying apparatus to satisfy special conditions.

[An automatic watering device] (*Deut. Landw. Presse*, 39 (1912), No. 39, p. 463, figs. 2).—A device for watering stock is described which is operated by the weight of the animal pressing down the approach board. This action is transmitted to a pump, thereby supplying fresh water for each animal.

Preliminary tests of new milking apparatus, B. MARTINY (*Arb. Deut. Landw. Gesell.*, 1912, No. 211, pp. 107, figs. 11).—A report of the methods and results of tests of 3 milking machines, giving a description of each machine and a general discussion of test results.

[A cream separator] (*Indus. Latt. e Zootec.*, 10 (1912), No. 10, pp. 153, 154, figs. 3).—A description is given of a separator which can be operated by hand or motor, with the results of 10 tests.

[Report of competitive tests of refrigerating and cold storage apparatus], B. MARTINY (*Arb. Deut. Landw. Gesell.*, 1912, No. 210, pp. 24, pls. 3, figs. 10).—Descriptions are given of the construction and operation of refrigerating and cold storage apparatus designed more especially for dairy use, with the methods and results of competitive efficiency tests. The machines included self-acting refrigerators, hand and motor-driven coolers, and refrigerating and cold storage apparatus operating on a large scale. Some of the test results are graphically presented.

A small dairy house (*Farmers' Rev.*, 44 (1912), No. 20, pp. 537, 541, fig. 1).—The essential factors to be considered in dairy house construction are pointed out, especially the need of drainage, cleanliness, ventilation, and sunlight, and the construction and equipment of a small dairy house recommended by this Department are described.

The silo for Missouri farmers, C. H. ECKLES (*Missouri Sta. Bul.* 103, pp. 293-305, figs. 4).—This is a bulletin of information for the Missouri silo user or prospective builder. Tables stating the tonnage capacity of silos of various sizes, and the proper capacity to build for herds of given sizes are followed by descriptions of different silo types; suggestions on crops for the silo; directions for cutting, filling, and feeding; and a brief list of bulletins on silos and silage.

## RURAL ECONOMICS.

The organization of country life, W. M. HAYS (*Farmers' Nat. Cong. U. S., Proc.*, 31 (1911), pp. 139-146).—An address delivered at the Farmers' National Congress, Columbus, Ohio, October 12, 1911, in which the author discusses at length some phases of eugenics as applied to agriculture and the rural population of this country. He suggests the organization of country life interests into a great delegate body, representing all the departments, institutions, and associations of national and state scope which are devoted to the upbuilding of country life, and this organization in turn to be federated with the Federation of Women's Clubs, the Federation of Labor, the National Manufacturers' Association, the Association of Railways, and other large organizations. Such a general federation he thinks could work out in a large way many things which would make for the prosperity and happiness of the whole people.

What is farm management? How does it help the practical man to solve his problems? W. J. SPILLMAN (*Tribune Farmer* [N. Y.], 11 (1912), No. 551, pp. 3, 17, fig. 1).—This article presents a discussion of what constitutes farm management, and the scope of its application. The author refers to it as "an old practice, but a new science—choosing the best type, organizing, and equipping the farm to the best advantage, and operation to secure the best utilization and distribution of equipment and labor are prime essentials."

**Agricultural credit and its reorganization**, TROSIEN (*Der Landwirtschaftliche Kredit und Seine Durchgreifende Verbesserung*, Berlin, 1911, pp. VII+84).—The results of an economic study of agricultural credit and its reorganization in Germany are presented and discussed. It is pointed out that the increase in running expenses in agriculture has exceeded the increase in the amount of money available for loans on land, thereby making more necessary the freeing of agriculture from debt. The privileges of mortgage holding are discussed and the necessity of their removal to the advantage of agricultural personal credit is explained.

**Adaptation of the European credit system to meet the needs of the American farmer**, D. LUBIN (*U. S. Senate, 62. Cong., 2. Sess., Doc. 855, 1912, pp. 14*).—This document presents a report made to the International Institute of Agriculture on the conference held at Nashville, Tenn., April 1-6, 1912, looking to the appointing of a select committee from the various States in the Union to go to Europe and investigate rural cooperative credit systems in operation there with a view to adapting them to the needs of American agriculture.

A number of suggestions are offered as a solution of the rural finance problem in the United States, among them the establishment of a system of agricultural national banks.

“One plan would be for the incorporation or cooperative association of groups of farmers, when they could devise and offer as security for the money they require a negotiable bond on their collective assets, a bond at a valuation and of a character which should make it acceptable in the world of commerce and in so liquid a form as to require no lawsuit for foreclosure. This bond could then be offered in the open market, and the funds for the cooperative banking be thus obtained. These funds could then be employed, first, for the use of the individual members of the cooperation, and, second, for the collective use of the cooperation as a whole in swinging its product to market; in its distribution.”

A modification of this plan might be had by the formation of rural national banks, on the order of the existing national banks. “Let the cooperative groups of farmers call on government bond owners to transfer their bonds to these farmers’ groups. Let the farmers pay the bond owners, say 1 per cent per annum for the privilege of this transfer. Let them deposit these transferred government bonds, along with their own negotiable land bonds, in the United States Treasury, where they would be held in trust for both parties by the United States. On the security of these government bonds the United States could issue national rural bank notes to these cooperative groups of farmers, just as it does in the case of national banks. The United States bond owner would then receive interest on his coupons, plus the 1 per cent per annum extra from the farmers’ cooperative groups. These groups would thus have money at 1 per cent per annum, and the government bond owner would have as security a negotiable bond on the collective property of the farmers’ cooperation, security which would exceed in value the United States bond deposited in the Treasury. In substance, the negotiable bond for this property and the government bonds would both be held in trust by the United States Government, which would simply act as umpire between the bond owners and the farmers, and thus this transaction would be free from any phase of so-called socialism.”

**A cooperative sugar factory in Holland**, J. W. ROBERTSON-SCOTT (*Jour. Bd. Agr. [London], 18 (1912), No. 12, pp. 1014-1017, pl. 1*).—This article notes what is being done in the way of cooperative manufacture of sugar by farmers in Holland. One of the first factories established was in 1909 with 3,000 shares and

300 members, each paying £8 4s. per share. The figures in the following table show results of its working since beginning operation:

*Work of cooperative sugar factory at Dinteloord, 1909-1912.*

Years.	Number of members.	Number of shares.	Beets handled per season.	Beets handled daily.	Price paid per ton.
1909-10.....	644	3, 150	<i>Tons.</i> 65, 000	<i>Tons.</i> 1, 038	21s. 8d.
1910-11.....	704	3, 368	87, 000	1, 333	25s. 1d.
1911-12.....	720	3, 430	119, 000	1, 400	28s. 4d.

"From the farmers' point of view, the cooperative factory is no doubt the ideal way of going to work." In this way the farmer gets his profits as beet grower and his dividend as a sugar manufacturer, it being stated that for the season 1911-12, "the members will be paid about 8s. 4d. more per ton for their beets than they would have got . . . from the joint stock companies."

[Compulsory insurance against sickness and unemployment] (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intl., 3 (1912), No. 4, pp. 103-119*).—This article presents a discussion of the national insurance act of Great Britain and Ireland, which provides for the compulsory insurance of practically all persons employed in the United Kingdom under any contract of service or apprenticeship. The fund from which the insured are paid is raised by contributions from the State, employers, and the insured persons. The compensation for men is 7d. per week, for women 6d. "Where the rate of remuneration exceeds 1s. 5d. but does not exceed 2s. a working day, the State will pay 1d. per week, the employed contributor 1d. per week, and the employer 5d. for men and 4d. for women." Other data pertaining to the provisions and enforcement of the act are given, also a lengthy bibliography.
